ABSTRACT BOOK
SETAC Europe 29th Annual Meeting

TABLE OF CONTENTS

This book compiles the abstracts from the platform and poster session presentations at the 29th Annual Meeting of the Society of Environmental Toxicology and Chemistry- Europe (SETAC Europe), conducted at the Messukeskus Helsinki, Expo and Convention Centre, Helsinki, Finland, from 26–30 May 2019.
The abstracts are reproduced as submitted by the author and accepted by the Scientific Committee. They appear in order of abstract code and alphabetical order per presentation type. The poster spotlight abstracts are included in the list of poster abstracts. The presenting author of each abstract is underlined.

SOCIETY OF ENVIRONMENTAL TOXICOLOGY AND CHEMISTRY
In the 1970s, no forum existed for interdisciplinary communication among environmental scientists, biologists, chemists, toxicologists, managers, engineers or others interested in environmental issues. The Society of Environmental Toxicology and Chemistry (SETAC) was founded in North America in 1979 to fill the void, and quickly saw dynamic growth in the Society's membership, meeting attendance and publications.

A unique strength of SETAC is its commitment to balance the scientific interests of government, academia and business. The Society by-laws mandate equal representation from these three sectors for officers of the World Council and Geographic Unit Boards of

Directors and Councils, and in the composition of committees and other society activities. The proportion of members from each of the three sectors has remained nearly equal over the years.

The Society is concerned about global environmental issues. Its members are committed to Environmental Quality Through Science®, to timely and effective communication of research, and to interactions among professionals so that enhanced knowledge and increased personal exchanges occur. Therefore, SETAC publishes two globally esteemed scientific journals and convenes annual meetings around the world, showcasing cutting-edge science in poster and platform presentations. Because of its multidisciplinary approach, the scope of the science of SETAC is broader in concept and application than that of many other societies.

SETAC's growth is reflected in the founding of geographic units around the world. SETAC Europe was established in 1989 as an independent organisation, followed by SETAC Asia-Pacific in 1997 and SETAC Latin America in 1999. In 2002, the four existing organisations joined together under the governance of the SETAC World Council. SETAC Africa is the most recent geographic unit, which was adopted in 2012. As evidence of international acceptance of the SETAC model and of the great interest at the local level, regional chapters and branches have emerged in a number of countries.

SETAC publishes two journals: *Environmental Toxicology and Chemistry* (ET&C) and *Integrated Environmental Assessment and Management* (IEAM). Environmental Toxicology and Chemistry is dedicated to furthering scientific knowledge and disseminating information on environmental toxicology and chemistry, including the application of these sciences to risk assessment. Integrated Environmental Assessment and Management focuses on the application of science in environmental decision-making, regulation, and management, including aspects of policy and law, and the development of scientifically sound approaches to environmental problem solving. Together, these journals provide a forum for professionals in academia, business, government, and other segments of society involved in the use, protection, and management of the environment for the enhancement of ecological health and human welfare.

SETAC books provide timely in-depth reviews and critical appraisals on scientific subjects relevant to understanding a wide range of contemporary topics pertaining to the environment. These include any aspect of environmental chemistry, toxicology, risk assessment, risk management, or environmental policy.

SETAC has two administrative offices, in Pensacola, Florida, USA, established in 1992, and in Brussels, Belgium, established in 1993.

Keynote Sunday

One Health, Persistent Organic Pollutants and the Arctic

Cynthia A. de Wit, Department of Environmental Science and Analytical Chemistry, Stockholm University, Stockholm, Sweden

The One Health concept is based on understanding how human, wildlife and ecosystem/planetary health are interconnected and the Arctic has long served as an early warning system in this regard. Persistent organic pollutants will be used to illustrate this, for example, the early discovery of PCBs in the Arctic in the 1970s, and subsequent studies of PCBs in wildlife and humans in the Canadian Arctic in the 1980s. The very high levels found in top predators and some indigenous populations in what was supposed to be a pristine environment was devastating news. Indigenous peoples' traditional foods, crucial for their health, society and culture were now highly contaminated. These and other findings led the eight Arctic countries to call for an assessment of the Arctic environment. A report on POPs, other contaminants and human health in the Arctic environment was presented by the Arctic Monitoring and Assessment Programme in 1998.The science presented led to new understanding of pathways and processes for POPs into and within the Arctic, including biomagnification in food webs and humans, and effects of exposure. It illustrated succinctly how interconnected the Arctic was to the rest of the world, and was a driving factor in development of regional and global POPs regulation, such as the Stockholm Convention. Further protection of the Arctic from new chemicals is thus crucial to protecting humans, wildlife and ecosystems globally.

Keynote Monday

Can One Environment, One Health and Many Chemicals be Sustainable?

Bjorn Hansen, European Chemicals Agency (ECHA), Finland

With the adoption in 2015 of the Sustainable Development Goals the world embarked on an ambitious journey to obtain a sustainable future by 2030. Chemicals management has a specific target within Sustainable Development Goal 14 is "By 2020, achieve the environmentally sound management of chemicals and all wastes throughout their life cycle, in accordance with agreed international frameworks, and significantly reduce their release to air, water and soil in order to minimize their adverse impacts on human health and the environment". The EU is settings its chemicals and waste policies, within the EU and internationally, to meet this goal.

The EU has also set an ambitious goal of moving towards a circular economy. Achieving circularity requires significant advances in product design, in material development, in collection and recycling/recovery. At the core are materials –as it is the material which gives the product its desired functionality and enables recycling or recovery. For those working in the chemicals area a material is a mixture.

To achieve the sustainable development goals in an EU moving towards a circular economy, requires innovation in chemistry to develop the chemicals which make up circular materials and which minimize the adverse impacts on human health and the environment. There is though much which needs to be put in place to achieve this: from chemicals and waste legislation, from research and industry. But meeting the challenge is a necessity if we want to protect our one environment, provide protection for all citizens and ensure that chemicals can be used to maintain our wellbeing!

Keynote Tuesday

Environmental Pollutants and Health

Jorma Toppari, University of Turku, Finland

Environmental effects on health are in many cases preventable in contrast to genetic impact. Industrial chemicals have been produced only during the last 150 years and the production has multiplied during our time. Unfortunately many of the good products turned out to be bad pollutants affecting our health. Thanks to the Stockholm convention, the amount of persistent organic pollutants is declining, and now the main attention is on less persistent compounds that interfere with physiology, including endocrine and immune systems, central nervous system, and most importantly, their development. The incidence of non-communicable diseases in increasing and many environmental chemicals are associated with their pathophysiology. Endocrine disrupting chemicals can contribute to reproductive disorders and cognitive development by inhibiting hormone production and action at critical developmental phases. Anti-androgenic chemicals cause genital malformations and poor semen quality experimentally and most likely in humans, too. Anti-thyroid chemicals can cause severe adverse effects in central nervous system in fetuses and infants. Currently the greatest problem is the lack of knowledge about the health effects of the majority of chemicals in use.

Keynote Wednesday

Innovation Where Everyone Wins: A Call for a New Dialogue in Environmental Toxicology, Chemistry and Risk Assessment

Juan Gonzalez Valero, Syngenta, Switzerland

Since the early days in environmental sciences we have constantly increased our understanding off the impacts of human activities and technologies on the environment. We are experts in exploring risks and it is only logical that we focus our effort on avoiding the risk from those activities. We know that we don't have all the answers and have to apply precaution. But we shouldn't confuse precaution with avoidance. Avoiding innovation means avoiding progress, and without progress there will be no better outcome: not for humans and not for nature. As environmental scientist we are in a dilemma. The possible trade-offs are complex and require a different form of dialogue that pushes us all out of our comfort zone. A common reaction is to push decisions to the political level with detrimental effects on safeguarding and improving the quality and credibility of science in environmental toxicology and chemistry. We should rather shape a better and more inclusive science dialogue that focuses on the multiple facets of innovation benefits and risks based on reproducible science, unbiased data, analysis, interpretation and disclosure.

Micro(Nano)plastic Pollution: Tackling the Plastic Problem by Identifying Sources, Investigating Fate and Novel Approaches (I)

1

Tracking the origin of fiber micro-fragments in textiles and understanding the release mechanism during washing

Y. Cai, T. Yang, Empa Swiss Federal Laboratories for Materials Science and Technology; D.M. Mitrano, Eawag - Swiss federal Institute of Aquatic Science and Technology / Process Engineering; M. Heuberger, Empa Swiss Federal Laboratories for Materials Science and Technology / Laboratory for Advanced Fibers; R. Hufenus, Empa Swiss Federal Laboratories for Materials Science and Technology; B. Nowack, Empa Swiss Federal Laboratories for Materials Science and Technology / Technology and Society Lab

As an important source of microplastics into the environment, many efforts have been made to understand the release (mechanisms) of fiber micro-fragments (FMFs) from synthetic textiles during washing. However, the factors of the materials, finishing processes and washing conditions controlling these releases still remain unclear. The aim of this work was to investigate the formation of FMFs during fiber and fabric manufacturing and the mechanism controlling the FMF release during washing. An extraction method was developed to investigate the FMFs formed through the production chain of textiles. Several representative polyester products along the production line including a sliver, three types of yarns and eleven kinds of fabrics were collected. The extraction was performed by sequential ultra-sonication and the released fibers were collected on filter. In this way, we developed a method to decouple the release of FMFs that were already in the textile sample from the potential formation of new FMFs from mechanical stress during washing. The FMFs were imaged and analyzed to obtain the length and the number. The second experiment was performed with a gyrowash machine and a standard wash cycle mainly based on an ISO washing standard. Additional experiments were performed to understand the influence by washing time, mechanical stress and concentration of detergents. The extraction experiment showed that after three to nine 10-minute sonication steps, the release of FMFs dropped to almost zero, indicating that sonication less than 90 minutes did not produce FMFs but was rather releasing what is already present inside the fiber or fabric. The release was affected by the type of fiber (e.g. staple fiber), the fabric structure and the cutting method. Those fabrics which showed higher releases in the extraction experiment also shed more FMFs during washing. We observed a decrease of the released FMFs with the number of washing cycles, indicating that formation of FMF during washing is very low. The number of FMFs extracted by ultrasound and the FMF release during washing was in the same magnitude and demonstrated a linear correlation suggesting that the washing process is likely only shedding FMFs embedded in the fabric instead of producing new ones. The results of this work will establish a deeper understanding of the origin of the FMF released from textiles and may form the basis for engineering options to reduce FMFs in new fabrics being produced.

2

PLASTIC-Seine research project: Microplastic Flux and Impact on biota in the Seine estuary

j. gasperi, S. Alligant, LEESU; B. Tassin, LEESU / LEESU laboratoire eaux environnement et systèmes urbains; M. Revel, C. Mouneyrac, Catholic University of the West; M. Mouloud, A. Chatel, H. Perrein-Ettajani, M. Bruneau, Catholic University of the West / UBL Mer Molécules Santé; M. Halm Lemeille, A. Gangnery, f. galgani, M. Bégout, IFREMER; X. Cousin, IFREMER / Laboratoire de Ressources Halieutiques de La Rochelle; C. Dreanno, M. El Rakwe, IFREMER; J. Thery, C. Bialais, S. Souissi, M. Kazour, R. Amara, Université de Lille; M. dutertre, SEBIO UNIVERSITE LE HAVRE; R. Coulaud, SEBIO UNIVERSITY OF LE HAVRE; T. Monsinjon, SEBIO UNIVERSITE LE HAVRE / UMR-I 02 INERIS-URCA-ULH Environmental Stress and Aquatic Biomonitoring (SEBIO); B. Xuereb, SEBIO UNIVERSITY OF LE HAVRE; C. Clérandeau, F. Le Bihanic, c. vignet, P. Pannetier, University of Bordeaux / EPOC UMR; B. Morin, J. Cachot, University of Bordeaux / EPOC

Microplastics (MP) pollution is of emerging concern. Although numerous studies were recently carried out on freshwater and biota contamination, studies focused on estuary ecosystems are scarce. Estuaries can indeed play a significant role in the transport and transfer of MP to the ocean and the estuarine hydrodynamics and salinity gradient can greatly affect both MP distribution and concentrations, as well as the occurrence and levels in biotic compartments. In this context, the Plastic-Seine project (2017-2020) involving six French laboratories was launched to study the occurrence and levels of MP in all compartments of the ecosystem of the Seine River estuary (France). The objectives are: i) to study the occurrence and levels of MP in the Seine estuary for abiotic compartments (water column and sediment), ii) to study the ingestion and levels of MP for seven emblematic species of the Seine estuary, i.e, the worm *Hediste diversicolor*, the copepod *Eurytemora affinis*, the mussel *Mytulis edulis*, the prawn *Palaemon longirostris* and 3 fish species *Platichthys flesus*, *Solea solea* and *Dicentrarchus labrax* and iii) to assess the potential impacts of MP exposure on biology traits, physiology and behavior of three species (*Hediste diversicolor*, *Eurytemora affinis* and *Solea solea*). Preliminary and main results are here presented and discussed. First results on abiotic compartements highlighted the presence of fibers and fragements in both the water colonn and sediments. Particles exhibited different forms depending on their origin and/or fragmentation. Most of particles were inferior to 1 mm and a high proportion of fragments and films was higlighted. Slight MP distribution changes were also observed between surface water and subsurface water. For the seven species, MP including fibers and fragements were found. The others analyses are in progress. For all species, a high variabilities between species and individuals was highligted. High presence of fragments were noticed for seabass and worms in comparison to other species. In the case of prawns, a large amount of MP and especially of fibers were also observed on the cuticle surface. Futher studies will investigate the potential impacts of MP exposure on biology traits, physiology, and behavior of three estuarine species and the MP trophic transfer to common sole's food chain.

A comprehensive investigation of microplastic contamination in Lake Mjøsa, Norway's largest lake

A. Lusher, NIVA Norwegian Institute of Water Research / Environmental Contaminants; N. Buenaventura, NIVA Norwegian Institute for Water Research / Environmental Contaminants; D. Eidsvoll, Norwegian Institute for Water Research NIVA / Ecotoxicology and Risk Assessment; J. Thrane, NIVA Norwegian Institute for Water Research / Pelagic freshwater ecology; A. Økelsrud, NIVA Norwegian Institute for Water Research; M. Jartun, NIVA Norwegian Institute for Water Research / Environmental Contaminants

Plastic is a ubiquitous contaminant in the environment, this includes microplastics (< 1 mm) which have been found globally. Some microplastics are released directly into the environment whereas others break down from larger plastic items because of environmental processes. The widespread presence of microplastics in the environment highlights the need to understand the sources for microplastics and the consequences of this contamination. In this current project, our aim was to contribute to knowledge concerning microplastic contamination in freshwater environments. To do so, an assessment of microplastic contamination in the largest lake in Norway, Lake Mjøsa, was carried out looking at sediments, biota and water samples. Microplastics were identified in all core slices (0-1cm, 1-2cm, 2-3cm) across twenty stations with varying anthropogenic sources of input. Polymer composition varied between sites and core depth. For example, polyamide was less abundant in deeper core slices, polycarbonate was found at three sites and polyvinyl chloride was only found at one site. In addition, microplastics were identified in 9/12 historical plankton samples dated 1973 to 2017. Only a single duck mussel was found to contain an orange synthetic rubber fragment (339 x 233 μm). In forthcoming months, the deeper core slices (3-4 cm, 7-8cm) will be assessed and compared to the currently complied data. This study will also be essential for sealing the knowledge gaps in microplastic studies, which will enable this field to be further developed and provide a better understanding of the effects and impacts of microplastics in the environment. The results from this study will form the basis for a recommendation for further monitoring of microplastics in Lake Mjøsa, and in freshwater in general.

4

Assessing the relevance of wastewater and agricultural runoff as microplastic sources for freshwater ecosystems: A case study in central Spain

T.C. Schell, IMDEA Water Institute / Ecotoxicology; R. Hurley, NIVA - Norwegian Institute for Water Research; A. Rico, IMDEA Water Institute / Aquatic Ecotoxicology; L. Nizzetto, Norwegian Institute for Water Research NIVA; M. Vighi, IMDEA Water Institute / Earth and Environmental Sciences

Microplastics (MPs) in wastewater are mostly retained in the sludge during wastewater treatment. Despite the high trapping efficiency of wastewater treatment plants (WWTPs), treated wastewater can act as a considerable source of MPs if large quantities are discharged. Sludge applied as fertilizer on agricultural fields may act as an additional MP source for freshwater ecosystems if MPs are transported by water runoff. However, no data is indicating the relevance of this environmental pathway. This study aimed to comparatively assess the contribution of WWTP effluents and runoff from agricultural fields as sources of MPs into freshwater ecosystems, and to assess MPs concentrations and composition in streams receiving such pollution sources. The study was conducted in the Henares River Watershed (central Spain). MP concentrations were monitored in treated and untreated wastewater and sludge from five different WWTPs. An experiment was performed to assess the MP concentrations in runoff from agricultural fields. For this, three plots (2 m^2) with comparable soil characteristics but differing sludge applications were prepared: control soil (never treated with sludge), soil treated in the past (in 2013), and soil treated at the start of the experiment (in November 2017). Runoff samples were collected throughout one year. Additionally, the MP concentration was monitored at three different river sites: i) low human impact; ii) agricultural impact; and ii) urban, agricultural and

industrial impact. All water samples were taken by filtering sufficient amounts of water (river or wastewater) through a battery of plankton nets with different mesh size (300, 150, 55, 20 μm). Following MP extraction, the number and polymer composition per sample were assessed. Initial results (based on MPs > 150mm) show that 58% to 99% of MPs are retained during wastewater treatment, but still, up to 400 MPs/m^3 are emitted. The runoff experiment shows that MPs are present and mobilized via runoff water from all plots, but the highest concentration (1.36 MP/L runoff or 14.5 MPs per m^2) was observed in the most recently treated plot. To our knowledge this is the first study evaluating the contribution of sewage sludge to MP freshwater contamination. The results indicate that both, treated wastewater and runoff from sewage sludge treated fields, can act as a MPs source for aquatic ecosystems and should be taken into account in risk assessments performed at the watershed scale.

5

Matrix-adapted methodologies for qualitative and quantitative study of microplastics in marine bivalves and sediment

N. Phuong, Universite de Nantes / MMS; A. Zalouk-Vergnoux, Univeristé de Nantes / MMS; f. lagarde, Institute of molecules and materials of Le Mans / Institute of Materials and Molecules of Le Mans IMMM UMR CNRS; C. Mouneyrac, Catholic University of the West / UBL, Mer Molécules Santé; L. Poirier, Universite de Nantes / MMS

About 335 million tons of plastics were produced in 2016 and this production is increasing every year, due to their numerous properties and resulting societal benefits. The distribution of MPs in the environment depends on various inherent factors. The omnipresence of MPs has been demonstrated by scientists in recent years, particularly in marine ecosystems. Sediments are generally recognized as a large contaminated environmental compartment. But fauna is also affected, especially filter-feeder species. The aim of this work was to develop and validate rapid methodologies for assessing the MP contamination in sediment and bivalves (mussels: *Mytilus edulis* and oysters: *Crassostrea gigas*) from the French Atlantic coast (Pays de la Loire region, France). Surface sediments (0 to -5 cm) and bivalves were sampled at three locations and in two seasons: October 2015 and March 2016. Ten replicates of 25 g of sediment, 10 pools of 3 mussels and 10 individual oysters were analyzed per sampling location and season, leading to a global analysis of 60 sediment samples, 180 mussels and 90 oysters. In order to analyze the MPs, rapid protocols were adapted to the matrix and validated using spiked samples for isolation and identification of MPs without visual sorting. Good recoveries were obtained in the validation tests with values ranging from 78 % to 107 % depending on MP types. A total of 10 different types were found with a majority of PP and PE. Average levels ranged from 38 (± 47) to 102 (± 105) MP per kg of dry sediment (N = 10; 250 g). The whole abundance of MPs found in mussels and oysters respectively were about 0.23 (± 0.20) and 0.18 (± 0.16) MP per gram of wet weight soft tissues and about 0.60 (± 0.56) and 2.10 (± 1.71) MP per individual. It exists inter-compartment and interspecific differences on type, size and color of MPs. Globally, more than 80% of MPs were fragments, the remaining were filaments. None of granule or pellet were found. MP color showed high proportion of grey to light-grey. This littoral region adjacent to the Atlantic Ocean gathers significant areas of aquaculture at national level, for which the characterization of MP contamination is of great concern. Therefore, monitoring the presence of MPs in marine areas is currently of high importance as some of the organisms, such as mussels and oysters, are harvested by humans. This work provided the first dataset for this aquaculture area of great socio-economic importance.

6

Microplastic debris in an Italian river: first monitoring results

c. campanale, National Research Council, Water Research Institute; G. Bagnuolo, C. Massarelli, Italian National Research Council; V. Uricchio, Italian National Research Council / Water Research Institute

Plastic and microplastic pollution is one such emerging concern. Plastic pollution in the marine environment is well documented, however, there is a lack of knowledge for freshwater and terrestrial environments in terms of the extent, occurrence and impacts. Herein we report results from a monitoring study aimed to investigate about abundance, type, composition, and potential implications of microplastic in an Italian river (Ofanto river), evaluating at the same time the presence of temporal trends in response to hydrological parameters (flow velocity, water level of river and precipitation). River surface microplastic samples were collected during five monitoring campaigns (February, April, October, December 2017 and May 2018);all of them were taken from the same point located at 6 km from Ofanto river mouth. In order to reduce the spatial variability, microplastics were collected by three surface plankton nets of 333µm mesh size fixed in the middle of the river simultaneously for two different time slot for a total of six replicates for each campaign. Chemical digestion was performed to each sample in order to remove the labile organic matter and extract all the particles. After processing, a visual and chemical characterization has been carried out. Each particle visually identified, was counted, photographed, enumerated, and categorized according to size, color and morphology. Microplastics were found in each net sample for a total of 42,725 items counted, photographed, enumerated and categorized. Microplastic content measured in Ofanto river (expressed as mean value ± dev.st.) ranged from 0.9 ± 0.4 p/m^3 to 12 ± 5 p/m^3 showing values comparable to or greater than those reported in other studies, although there are few other freshwater studies to which to compare. A statistically significant difference in the average microplastic concentrations found in different campaigns of this study, has been observed, suggesting thus a temporal variation in plastic abundances. These differences could be explained by the hydrology of the river that influence, with physical forces the concentrations of particles. Microplastics were found at higher concentrations during wet periods (February 2017 and May 2018) indicating a presumable land-based origin probably from surroundings agricultural areas. The work reported here is the first study showing an Italian river context that provides an initial assessment of the extent and nature of this pollution in Ofanto river.

Effect Modelling for Regulatory Risk Assessment: Current Applications and Future Directions (I)

7

Integrating Semantic Technologies in Environmental RiskAssessment: A Vision

E.B. Myklebust, NIVA - Norwegian Institute for Water Research / Enviromental Data Science; K. Tollefsen, NIVA / Ecotoxicology and Risk Assessment; E. Jimenez-Ruiz, University of Oslo / Department of informatics; Z. Rudjord, R. Wolf, NIVA

Extending the scope of risk assessment models is a long-term goal in ecotoxicological research. However, biological effect data is only available for a few combinations of species–chemical pairs. We aim at designing tools based on semantic technologies to improve risk assessment analysis.\n\nRisk assessment requires the use of different metadata, e.g., from taxonomies, chemicals, or toxicity data. In addition, data collected by researchers in the field or the lab is used as direct input. A partial goal of our work is to effectively use semantic technologies to link these datasets together. These metadata form the basis of a knowledge graph. We add an ontological layer onto the knowledge graph, this includes rules and axioms to either validate or expand the data.\n\nExpanding the data can be done by two approaces, inductive and deductive.\n\nFirst approach considers adding axioms (e.g. ``all Solibacteres is also Bacteria") to the data ontology such that we can use reasoning to increase the available data for the risk assessment.\n\nThe alternative takes a probabilistic approach, using a machine learning model to give a probability of a entity beeing similar to another based on the data. To replace the function of the axioms as an explainer for adding new data, we introduce a new module, that uses the metadata ontology to inform the user about the uncertainty involved in the prediction.\n\nWe develop robust case studies to test system development. We need cases with a complete qualitative performance analysis, compared to previous single compound analysis. A simple such study could include pesticide montoring, NCBI taxonomy, and effects data in the for of ECOTOX.\n\nThis approach will yield new insight by combining and inferring from available data and subsequently improve the quality of risk assessment.

8

QSAR models in ecotoxicology: why such lack of faith?

P. Bicherel, F. Sahigara, KREATiS

Quantitative Structure-Activity Relationship models (QSARs) is one of the powerful alternatives to experimental tests. These statistical models based on semi-empirical approach are used to predict chemical properties based on their molecular structure. These tools are supported by the 3R principle promoting the Refinement, the Reduction and the Replacement of the experimentation performed on animals. Since decades, several QSARs have been developed to predict ecotoxicological and physico-chemical properties. Today many models are available through free software like EPISUITE, ECOSAR, T.E.S.T., VEGA etc. Despite their clear advantages, they have not been massively used as alternatives for REACH registration dossiers between 2009 and 2016. For the endpoints requested for Annexes VII-X and needing to test on vertebrates, QSARs were never the preferred option compared to in vitro studies, Read-Across or Weight of evidence strategies except for the bioaccumulation. In average they represent less than 5% of the endpoint study records. This striking under-use of the QSAR models has been investigated. Several free QSARs have been analysed through the 5 criteria of QSAR validation settled by the OECD among other criteria in order to highlight the main reasons of their feeble use. The principal causes identified are: the lack of transparency about the scientific method on which relies the modelling, the access of the statistics ensuring the performances of the model, the definition of the applicability and its systematic analysis for each prediction and finally the accuracy of the result and the measure of its uncertainty. Good and transparent modelling practises combined to the assessment of the prediction are essential to give credibility to QSARs outcomes.

9

Application of TKTD models in aquatic ERA for pesticides

T. Brock, Wageningen Environmental Research / Environmental Risk Assessment Team; M. Arena, EFSA - European Food Safety Authority / Pesticides; N.

Cedergreen, University of Copenhagen / Plant and Environmental Sciences; S. Charles, University Lyon 1 / Laboratory of Biometry and Evolutionnary Biology; S. Duquesne, German Environment Agency; A. Focks, Wageningen Environmental Research / Environmental Risk Assessment Team; A. Ippolito, EFSA - European Food Safety Authority / Pesticides Unit; M. Klein, Fraunhofer IME; M. Reed, HSE; I. Teodorovic, University of Novi Sad / Department of Biology and Ecology, Laboratory of Ecotoxicology (LECOTOX)

In 2018, the Panel on Pant Protection Products and their Residues (PPR) of the European Food Safety Authority (EFSA) published a scientific opinion on the state of the art of Toxicokinetic/Toxicodynamic (TKTD) models in prospective environmetal risk assessment (ERA) for pesticides and aquatic organisms (*EFSA Journal 2018;16(8):5377*). In this scientific opinion it is concluded that GUTS models (General Unified Threshold models of Survival; *Jager et al. 2011. Environmental Science and Technology, 45, 2529–2540*) are sufficiently developed to use them in the acute risk assessment scheme for aquatic invertebrates, fish and aquatic stages of amphibians to assess the risks of time-variable exposure. This presentation aims to illustrate the possible use of validated GUTS models, in combination with step 3 or step 4 FOCUSsw exposure profiles, as tools in the aquatic Tier-2 environmental risk assessment for an organophosphorus insecticide. This insecticide is characterised by short-term pulse exposures in edge-of-field surface waters. Experimental lower tiers indicate that aquatic arthropods (crustaceans and insects) in particular are at risk. The case study presented compares the outcome of the experimental effect assessment tiers (standard test species approach; geometric mean approach; species sensitivity distribution approach) with results of GUTS modelling to put these results into perspective. For the example insecticide selected, it appears that the application procedure of GUTS models in prospective ERA for pesticides as proposed by EFSA PPR (*EFSA Journal 2018;16(8):5377*) is promising to refine the risk of time-variable exposures. In addition, this Tier-2 assessment based on GUTS models was not in conflict with the principle of the tiered approach that lower tiers should be more conservative than higher-tiers. It is recommended that similar exercises are conducted with a representative number of substances differing in field exposure dynamics and toxic mode of action.

10

A roadmap for the use of TKTD models in ERA of pesticides

A. Ippolito, EFSA - European Food Safety Authority / Pesticides Unit; M. Arena, EFSA - European Food Safety Authority / Pesticides; T. Brock, Wageningen Environmental Research / Environmental Risk Assessment Team; N. Cedergreen, University of Copenhagen / Plant and Environmental Sciences; S. Teodorovic, University of Novi Sad / Department of Biology and Ecology, Laboratory of Ecotoxicology (LECOTOX)

Tier-1 risk assessments for pesticide active substances and Plant Protection Products (PPPs) in surface waters rely on the quantification of treatment-related responses from standard protocol tests, where exposure is continuous. When a low risk cannot be demonstrated with this conservative Tier-1 data, one possibility is to address the mismatch between the constant exposure regime used in standard ecotoxicity tests and the time-variable concentrations predicted in the field. Toxicokinetic-toxicodynamic (TKTD) models can be used to help in refining the assessment by predicting individual-level effects under untested time-variable exposure conditions. In order take stock of the state of the art and to provide some guidance about the use of TKTD models in the risk assessment, the EFSA Panel on Plant Protection Products and their Residues (PPR) developed a dedicated Scientific Opinion (SO). This presentation aims at introducing the assessment strategy suggested in the opinion, focussing specifically on GUTS models. Ten different evaluation areas have been identified and organised in checklists for each TKTD model type. For GUTS, due to the standardised nature of such models, some of these have been considered addressed once for all in the remit of the SO. On the contrary, other areas need to be carefully considered in the context of any substance-specific assessment. Among those, particular attention is paid to the parameter estimation (model calibration), to the evaluation of the sensitivity and uncertainty, and to the evaluation of the model by comparison with independent measurements (model validation). Finally, some implications for the testing strategy are also discussed in relation to the application of TKTD models for risk assessment purposes.

11

Measure or extrapolate? Extended parameterisation of TKTD models for population modeling under outdoor conditions

T. Strauss, Research Institute gaiac / gaiac - Research Institute for Ecosystem Analysis and Assessment; J. Klein, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Ecotoxicology; K. Rakel, Research Institute gaiac / gaiac- Research Institute for Ecosystem Analysis und Assessment

Recently, the toxicokinetic-toxicodynamic (TKTD) model framework GUTS is recommended to be used in regulatory risk assessment by EFSA. In the last few years, individual-based population models (IBMs) are being increasingly applied in risk assessment that take into account physiological temperature dependencies as well as the size structure of populations. These models are often coupled to TKTD effect models, and can be used for extrapolating variable exposure scenarios to population effects under outdoor conditions. However, TKTD models usually take neither temperature nor size dependencies into consideration, although temperature and animal size can have a strong influence on the parameters of TKTD models. TKTD models normally coupled to individual-based population models describe only the sensitivity which has been measured for one specific organism size at only one constant temperature. For practical reasons, it is not always possible to test the smallest and most sensitive stages of organisms in the laboratory. In addition, for a realistic effect modeling with dynamic population models, it is necessary to know the sensitivity of all relevant body sizes. Measuring sufficient combinations of size and temperature is expensive and time consuming. An alternative could be the extrapolation of the required TKTD parameters from laboratory standard tests. Therefore, we examine concepts which seems to be suitable for extrapolation from the size analyzed to other life stages or size classes and between different temperatures. This presentation exemplarily examines the influence of seasonality on population-level toxicity under realistic field conditions, which considers the dynamic and variable timing of toxic exposure, body size composition in a population, and environmental stressors over the year. For this purpose, an individual-based population model for *Daphnia magna* is used, which has been coupled to a lake ecosystem model, including the TKTD model GUTS, which now has been extended by temperature and body size dependencies. This model approach was used to analyse different scenarios with i) measured, ii) extrapolated, and iii) ignored temperature and size dependencies of the TKTD parameters. Therefore, ecological as well as exposure scenarios for summer and winter conditions were selected, and population size and recovery time were considered as model endpoints to assess toxic effects on the population level.

12

Toxicokinetic-toxicodynamic modelling of the effects of pesticides on growth of the laboratory rat, Rattus norvegicus

T.O. Martin, Environment Department, University of York / Environment Department; R. Ashauer, University of York / Environment; H. Thompson, Syngenta Ltd / Environmental Safety; P. Thorbek, Syngenta

Ecological risk assessment is carried out for chemicals such as pesticides before they are released into the environment. Such risk assessment currently relies on summary statistics gathered in standardised lab studies however, these statistics extract only very limited information and depend on duration of exposure so extrapolation to realistic ecological scenarios is inherently limited. Mechanistic effect models simulate the processes underlying toxicity and so have the potential to overcome such issues. Toxicokinetic-toxicodynamic (TK-TD) models operate at the individual level, predicting the internal concentration of a chemical over time and the stress it places on an organism. TK-TD models are particularly suited to addressing the difference in exposure patterns between lab (constant) and field (time varied) scenarios. So far we know very little about predicting sub-lethal effects of pesticide exposure to mammals, even though such effects are of particular interest with respect to longer term exposure. We demonstrate that TK-TD models based on the dynamic energy budget (DEB) theory can be used effectively with regulatory toxicity test data sets to predict toxic effects on the growth of rats over time. Model predictions can separate the impacts of feeding avoidance and toxic action, highlighting which was the primary driver of effects on growth. Such information is highly relevant to the ecological risk posed by a compound because in the environment alternative food sources may or may not be available to focal species. While this study focused on a single endpoint, growth, this approach could be expanded to include reproductive output. The framework developed is simple to use and could be of great utility for ecological research and to risk assessors in industry and regulatory agencies.

Latest Developments and Future Needs for Higher-Tier Studies, Risk Assessment and Risk Management in the Regulation of Biocides, Pesticides and Pharmaceuticals (I)

13

Investigating the lethal and sub-lethal effects of anti-sea lice therapeutants, used widely on salmon farms, on the European lobster (Homarus gammarus)

A. Parsons, University of Exeter / Biosciences; R. Escobar, A. Agnalt, O. Samuelsen, Institute of Marine Research

Sea lice are naturally occurring marine ectoparasites common in salmonid species, but in high numbers they present a serious problem for the salmonid farming industry. Sea lice infestations reduce the welfare of farmed fish and cause significant economic losses to the industry, estimated at €300 million annually around the globe. The industry heavily relies on the use of therapeutants added to the water or incorporated into fish feed to control sea lice infestations. These therapeutants enter the aquatic environment both directly, following the release of bath treatment effluents, or indirectly via the deposition of uneaten food pellets and/or faecal matter to the sea floor below the salmon pens. Although widely used, the acute and sub-lethal effects of these compounds on non-target crustaceans are not well known. We carried out a series of acute toxicity tests to assess the lethal and sub-lethal effects of deltamethrin and azamethiphos, two important neurotoxic pesticides, on European lobster (*Homarus gammarus)* larvae (stage I and II) following an environmentally relevant exposure scenario (1 h). Mortality and immobility were selected as lethal and sub-lethal toxic endpoints. We found that exposures to azamethiphos and deltamethrin were lethal to both larval stages examined, with 1h-LC_{50} values well below the concentration recommended to treat sea lice on salmon farms. Interestingly both compounds also caused significant immobilisation of larvae, and once immobilised the larvae were unlikely to recover up to 24 h post exposure. In field situations, immobile individuals would be incapable of maintaining their position in the water column, unable to avoid predators and unable to feed and therefore are considered to be ecologically dead. Since EC_{50} values (based on mortality + immobility) were substantially more sensitive than LC_{50} values, our results suggest that these compounds may pose a significant threat to non-target species and highlights the importance of considering EC_{50} values in risk assessment analyses of pesticides, particularly neurotoxic compounds such as azamethiphos and deltamethrin. We have also carried out an experiment examining the uptake and sub-lethal effects of emamectin benzoate (EMB), the leading in-feed anti-sea lice drug, in juvenile European lobster following a chronic (49 day) exposure. Sub-lethal effects examined included changes in gross morphology (body weight, carapace length) as well as transcriptional responses.

14
Micro-dams on potato fields: consideration in environmental risk assessment as part of the MAgPIE toolbox
S. Sittig, knoell Germany GmbH / E-Fate Modelling; R. Sur, Bayer AG - Crop Science Division / Environmental Safety; D. Baets, Bayer AG Crop Science Division / Sustainable Operations
On sloped agricultural fields, water and sediment can be transported downhill as run-off and erosion. This process can cause loss of valuable top soil material as well as transport of plant protection products (PPP) into adjacent surface water bodies. Farmers may use commercially available equipment to establish so called micro-dams between the rows of e.g. potato or maize fields to prevent run-off and enhance water infiltration. In European and US risk assessment for the registration of PPP, run-off is numerically calculated with the simulation model PRZM which uses the USDA run-off curve number (CN) concept for predicting the downhill transport of water and PPP with the runoff water movement. Results from run-off field trials were used to determine the effect of micro-dams between the ridges of potato fields on model input parameters. To this end, the relation between precipitation and runoff was used to derive CN. The impact on the actual risk assessment is shown with standard FOCUS-PRZM calculations of predicted environmental concentrations. A numerical study using the spatial model for runoff, floods and erosion openLISEM is shown to present an alternative way to estimate the run-off-reducing effect of micro-dams on potato fields. The results presented here support the approach to quantitatively consider in-field risk mitigation measures in the context of regulatory surface water exposure calculations, as proposed by the MAgPIE workshop. In the case of micro-dams, their mitigating effect can be quantitatively considered by reducing the CN in the exposure scenarios appropriately.

15
Higher tier testing- When reality does not meet expectations: a tale of two copepods
M. Staggs, Smithers Viscient / Ecotoxicology; M.J. Bradley, Smithers Viscient, LLC / Ecotoxicology; T. Mathieu, M.L. Johnson, Smithers Viscient / Ecotoxicology
Higher tier testing is a valuable tool in assessing the risk of plant protection products (PPP) to aquatic and terrestrial organisms; however, higher tier testing comes with a unique set of challenges. One of these challenges is determining which species to use when developing a species sensitivity distribution (SSD) based on standardized laboratory tests. When selecting species, there are some aspects to consider, such as whether or not there is a published guideline or test method, if there are defined endpoints and acceptability criteria, and if the organisms are readily available from a reliable supplier. While these are all critical aspects of a higher tier test, the most critical question for the performing laboratory is "can we successfully conduct this test?" Smithers Viscient conducted a series of full life-cycle toxicity tests to produce an aquatic invertebrate SSD for a PPP. Among the species selected for this program were two copepods, *Tisbe battagliai* and *Amphiascus tenuiremis*. Guidance for copepod testing exists in the form of a new guidance document in the OECD Series on Testing and Assessment, Number 201. The methods described in this guidance document are specific to *Amphiascus* and have been developed and validated through a series of inter-laboratory tests. *Tisbe* was initially included as a possible species during development of the test method, but was ultimately excluded due to inconsistent performance and a lack of interest among validation participants. Published literature on the use of *Tisbe* for laboratory toxicity testing is available, but no formal test method exists; therefore, several modifications to the 201 guidance document were necessary to conduct testing with *Tisbe*. With a formal, validated guidance document supporting *Amphiascus* as an appropriate test species, an expectation for success was set. Given the lack of supporting information on test methods with *Tisbe*, there was a greater uncertainty of success with this species and its fit within the SSD. This presentation will review the results of the toxicity tests conducted with these two species.

16
Optimising mesocosm study design to derive reliable and robust community endpoints
M. Brown, Cambridge Environmental Assessments (CEA); J. Ashford, Cambridge Environmental Assessments; N. Taylor, Cambridge Environmental Assessments (CEA) / Ecotoxicology
Aquatic freshwater mesocosms are designed to represent edge of field water bodies by creating a habitat that will support communities of aquatic macrophytes, algae, zooplankton and macroinvertebrates in a contained system. The EFSA guidance document on tiered risk assessment for plant protection products for aquatic organisms in edge-of-field surface waters [1], makes recommendations for a minimum of 8 sensitive/vulnerable taxa with acceptable minimum detectable difference (MDD) values to be tested. MDD values are useful in the interpretation of mesocosm data as they provide information on the probability that the statistical test will find differences between the treatment and controls. If MDD values are >100%, the power of the test is too low to demonstrate treatment related declines, therefore Brock provides further recommendations on the EFSA guidance for the improvement of MDD values and statistical power of mesocosm studies through improving the efficiency of sampling [2]. Sampling techniques that increase the number of individuals and reduce variability can reduce %MDD values. Therfore, it is vital to design and set up a mesocosm study that will support high species richness and abundance to achieve these requirements. Furthermore, the design of the individual mesocosm itself has an important role to play in the success of a study and the reliability of the data obtained. Here, we present case studies using historical CEA mesocosm data to highlight how improvemtents to mesocosm study designs based on the recommendations by Brock *et al*. affect MDD values. We will do this by conducting univariate statistics to calculate MDD values and comparing data from old mesocosm designs and new and updated mesocosm study designs. Improved mesocosm designs and sampling methodologies include using multiple plant health and growth measures, counting a higher proportion of phytoplankton sub samples and increasing the number of macroinvertebrate and emergent insect traps per mesocosm. Using these case studies we hope to demonstrate that our improvements to mesocosm study design will result in data that has the statistical power required to show community level effects. This is achieved by increasing the number of individuals counted in order to increase the statistical power and reduce %MDD values. In addition the improvement of measurement or sampling techniques that increase the number of endpoints can reduce variability and provide more reliable and robust data.

17
The field study conundrum
F.M. Bakker, Bakker Consultant; S. Aldershof, Bioresearch & Evaluation
Arthropod field studies are unique in providing comprehensive ecological complexity at a relatively small spatial scale. Arthropod communities are not only highly speciose, they also cover a broad spectrum of activity patterns, habitat use and autecological traits that ensure full coverage of potential exposure scenarios. This diversity at the scale of the farm or below suggests a high degree of spatial variability that may be at odds with replicated plot study designs. Indeed, variability is an epithet applied to field studies and usually in negative connotation, however mostly without specification. We evaluate different parameters that may describe different aspects of variability, in particular abundance, species composition and response to exposure. First, we look at pre-treatment variability in species abundance and discuss strategies to cope with pre-treatment variability. In addition to variability in abundance, arthropod communities may also vary in species composition. Again, this is often regarded as a potential issue when it comes to extrapolating study results. We compare an array of arthropod communities at different sites over a period of 10 years and evaluate their compositional similarity at an appropriate taxonomic level. Subsequently, we compare community responses to reference insecticide treatment for a range of field studies and evaluate the variability in observed response. Although definitely more realistic than any lower tier study or model, a field study still represents a worst-case situation. The direct overspray of hay meadows to simulate spray drift events ensures uniform exposure over extended areas. Likewise, the high spray volumes and restrictions on maintenance treatments in studies in commercial cropping systems are worst case. In technical regard field studies can be considered sufficiently protective. However, the match of spatial scale with species mobility traits may constrain the practical scope of field study results. We investigate whether plot sizes chosen for typical study durations match with motility records and evaluate the temporal pattern of recovery from insecticide treatment for a suite of arthropod taxa. Finally, for certain species, effects at larger spatial scales can be expected on theoretical grounds. We evaluate the potential for overlooking such "action at a distance" by comparing mobility and sensitivity of different taxa relative to most sensitive species endpoints.

18
Avian reproduction under real conditions: how to deal with variability and extrapolation in bird nest monitoring studies
A. Russ, Tier3 Solutions GmbH; R. Dittrich, Tier3 Solutions GmbH / Wildlife Ecology; M.M. Benito, Tier3 Solutions GmbH; S. Norman, RidgewayEco
According to the relevant guidance in the EU (EFSA guidance document 2009, GD) nest monitoring is an option to verify acceptable risk of plant protection products (PPPs) to the reproductive performance of birds. Such a higher-tier study provides a maximum level of realism as all routes of exposure are included. Moreover, there are a range of well-established methodologies and statistical approaches for nest monitoring studies and sufficient sample sizes are relatively easy to obtain. However, as no detailed information is given in the GD about the appropriate study design there are concerns whether the natural variability can be covered and the extrapolation of results among different studies is questioned. Nest monitoring studies are thus an ideal example to discuss the regulatory expectations on higher tier studies and to demonstrate how guidance on the study design will help to deal with the issues of variability and extrapolations. A case study is used to illustrate the basic approach of nest monitoring studies in ERA for PPPs. Breeding parameters were monitored for tit species in conventional (applied with organophosphate [OP]) and organic pome fruit orchards in 2013 and 2014 in UK. The fate of nests was monitored at fixed intervals. The data evaluation included endpoints used in avian reproduction lab tests and advanced statistics for nest survival (logistic exposure models) for each species. The breeding parameters obtained for great tit pairs were compared with published literature for the same species in pome fruit orchards in France. In total, the fate of 465 active nests was monitored. Despite of the natural variability, the main pattern underlying the nest survival could be identified. The model of nest survival revealed a significant effect of the breeding date and year. The nest survival probability was not significantly affected by the OP application. The values of the measured breeding parameters in the pome fruit orchards in UK are very similar to those obtained in France. This similarity shows that a typical situation was studied and provides great confidence that the observed absence of effects can be extrapolated to pome fruit orchards in general in the central zone. These results and the comparison with published data shows that nest monitoring studies can be a valuable tool in ERA of the PPP risk to birds and therefore they should be part of the revision of the EFSA GD on birds and mammals.

Endocrine Disruption in Invertebrates: Historical Perspectives, New Developments, and Key Research Needs

19
Levels and trends of tributyltin (TBT) and imposex in dogwhelk (Nucella lapillus) in Norway from 1991 to 2017
M. Schøyen, Norwegian Institute for Water Research (NIVA) / Centre for Coastal and Marine Research; N.W. Green, NIVA Norwegian Institute for Water Research / marine pollution; D. Hjermann, Norwegian Institute for Water Research NIVA / Oceanography; L.A. Tveiten, Norwegian Institute for Water Research NIVA / Marine Biology; B.A. Beylich, S. Øxnevad, Norwegian Institute for Water Research NIVA / marine pollution; J. Beyer, NIVA Norwegian Institute for Water Research / marine pollution
The banning of organotin biocides, such as tributyltin (TBT), from use in marine antifouling paints is leading to reproductive health recovery in marine gastropod populations all over the world. TBT induces so-called imposex (superimposition of male sexual characters onto females) in certain marine gastropods, such as the common dogwhelk *Nucella lapillus*. Imposex is caused by the ecotoxic non-target effect of organotin antifoulants. In this study, the results of the Norwegian TBT and imposex monitoring in *N. lapillus* from the period 1991-2017 are presented. TBT-exposed females can develop irreversible and non-functioning male sex characteristics such as a vas deferens and a penis like organ. In late stages of development, females may become sterile or even die prematurely causing imposexed snail populations to decline and sometimes go extinct. This biological effect in *N. lapillus* is quantified by the Vas Deferens Sequence Index (VDSI) and Relative Penis Size Index (RPSI). The TBT/imposex monitoring was conducted at eight coastal stations representing the Norwegian coast. Subsequently, 50 specimens from each station was analysed individually for imposex/VDSI and pooled (only females) for TBT. In 2017, no sign of imposex (VDSI=0) was found in *N. lapillus* in any of the monitoring stations along the Norwegian coastline, for the first time since the monitoring started in 1991. There were significant downward trends for both TBT and VDSI, or low levels. Good correlations between TBT and VDSI, TBT and RPSI, and VDSI and RPSI in *N. lapillus* were found. The legislation banning use of TBT (in 1990, 2003 and 2008) have been effective in reducing imposex/VDSI in *N. lapillus* and have re-established some of the populations. This monitoring data confirm the rationale of implementing strict international regulations on industrial chemicals when these can be linked to ecological perturbations in coastal ecosystems.

20
Do we need a paradigm shift in how we view mollusc endocrinology to protect molluscs from possible endocrine disruption?
A. Baynes, Brunel University London / Institute for the Environment
Molluscs make up a large and diverse phylum, second only to arthropods in the number of species. Molluscs are vital components of most ecosystems and are of great economic significance across the world both in terms of their value in aquaculture (e.g. oysters) and their impact as agricultural pest species (slug and snail damage) and as intermediate hosts for parasites (transmitting flukes and trematodes). Molluscs have also been subject to one of the best known cases of wildlife endocrine disruption caused by environmental chemicals, namely, the masculinisation of female marine gastropods, known as 'imposex', by the anti-fouling compounds such as tributyltin (TBT). Given the above, surprisingly there are still large fundamental knowledge-gaps in our understanding of mollusc developmental and reproductive endocrinology and misconceptions still prevail. For example, early gastropod imposex research initially suggested that TBT's masculinising effects were due to disruption to the steroid enzyme aromatase, and a subsequent increase in circulating androgen (e.g. testosterone) levels. In a vertebrate system this would certainly make sense as a driver of masculinisation. However, subsequent research has shown TBT's imposex effects are initiated via peroxisome proliferator–activated receptor (PPAR) and retinoid X receptor (RXR) interactions, and recent whole genome assessments for a number of mollusc species have found no homologous genes for aromatase and no mollusc nuclear androgen receptor. Nevertheless, ecotoxicology studies are still being published with mollusc 'aromatase' and testosterone levels given as biomarkers of chemical exposure. Recent research in our lab suggests that another steroid enzyme, 5-alpha-redutase which genomic evidence suggests molluscs do have, can be disrupted and has striking and highly reproducible developmental effects. I suggest that there is a pressing need to stop viewing mollusc endocrinology through a vertebrate lens and start focusing on the receptors, enzymes and transport proteins we know they have. We now have powerful molecular tools to investigate mollusc endocrinology, in order to understand the possible effect of environmental chemicals – we just need to start using them.

21
Daphnia as a test organism for endocrine disruption
D. Basili, Marche Polytechnic University / Deparment of Life and Environmental Sciences; P. Antczak, University of Liverpool / Institute of Integrative Biology; T. Iguchi, National Institute for Basic Biology / Molecular Environmental Endocrinology; K. Tollefsen, NIVA / Ecotoxicology and Risk Assessment; F. Falciani, University of Liverpool / Institute of Integrative Biology
Recently, there has been increasing evidence that chemicals that act as endocrine disruptors may have an effect in invertebrates, mainly insects and crustaceans. *Daphnia magna* has been proposed as a model organism for environmental ecotoxicology being a good biosensor for endocrine disruption because these chemicals may act by the juvenile and moulting hormone, endocrine hormones controlling development and growth. However, so far there is no direct evidence that all chemicals that are known endocrine disruptors in vertebrates truly act on this *D. magna* pathways. Here we address this question by first constructing gene expression signatures representing Daphnia response to both Juvenile and moulting hormones and then by comparing a panel of chemicals to the reference expression profiles of these two hormones. Interestingly, we identified Diazinon and Atrazine on one side and l-cyhalothrin and bifenthrin on the other one, to have a similar expression profile to either juvenile and the moulting hormone, respectively. We also set to experimentally validate our hypothesis. This finding is consistent with the working hypothesis that ED's act affecting these hormones signalling pathways. Our findings suggest that the approach we have developed could be used to identify novel endocrine disrupting compounds hence supporting the use of *Daphnia magna* for rapid screening in risk assessment

22
Disruption of Biological Rhythms by Environmental Stressors: An Ecdysteroid-Regulated Biorhythm
G.A. LeBlanc, S.M. Street, S.A. Eytcheson, North Carolina State University / Biological Sciences
Biological rhythms are maintained by molecular clocks that regulate diverse biological processes that maximize individual survival and population sustainability. Disruption of these rhythms by environmental chemicals and other stressors can compromise population-relevant processes such as development, growth, and reproduction. The molecular constituents of some of these molecular clocks have been well described (e.g. circadian clocks); while, others remain poorly understood. Among the latter are infradian clocks, time-keepers that maintain biological rhythms of greater than 24 hours. We used the infradian rhythm of molting in the crustacean *Daphnia magna* to develop a model for the regulation of this rhythm and to identify possible targets of disruption of the rhythm by environmental stressors. Results generated to date, support a molecular model for the regulation of the molt infradian rhythm as follows. Each cycle within the molt rhythm is initiated by a pulse of the hormone 20-hydroxyecdysone. This hormone induces the expression of two known clock proteins E75 and HR3. E75 suppresses the transcriptional activity of HR3 through dimerization. This dimerization stalls the clock mechanism and allows for sufficient time to pass for the development of embryos prior to their release at the

end of the cycle. Nitric oxide binds to E75 causing the release of HR3 from the E75 causing the resumption of the clock. HR3 induces the expression of the transcription factor FTZ. FTZ then induces the expression of enzymes involved in the next 20-hydroxyecdysone pulse. This pulse demarcates the end of one cycle and the beginning of the next cycle within the rhythm. Exposure of daphnids to suppressors of E75 expression or function extended the time required for the sequence of molecular events, increased time to reproductive maturation, reduced growth, lengthening of the period between molts, and reduced offspring production. All effects were consistent with our model for the regulation of this infradian rhythm. Results indicate that E75 may function as a target of chemically-induced disruption of this, and possibly other biorhythms. The simultaneous disruption of the multiple processes regulated by the infradian rhythm by environmental chemicals could have profound adverse consequences on population sustainability

23

Endocrine regulation and disruption of molting in arthropods: Mechanistic understanding and adverse outcome pathway development

Y. Song, Norwegian Institute for Water Research (NIVA) / Ecotoxicology and Risk Assessment; K. Toyota, Kanagawa University; C. LaLone, U.S. Environmental Protection Agency / Mid Continent Ecology Division; . Evensen, Norwegian University of Life Sciences; T. Rundberget, Norwegian Institute for Water Research; N. Reyero, US Army Engineer Research and Development Center; E.J. Perkins, U.S. Army Engineer Research and Development Center / Environmental Laboratory; T. Iguchi, YOkohama City University / Molecular Environmental Endocrinology; D.L. Villeneuve, U.S. Environmental Protection Agency / Mid-Continent Ecology Division; K. Tollefsen, NIVA / Ecotoxicology and Risk Assessment

Molting is key to growth, development and reproduction in arthropods, and is precisely regulated by ecdysteroids through activation of the ecdysone receptor (EcR). Endocrine disrupting chemicals (EDCs) mimicking the actions of ecdysteroids have therefore been developed as pesticides to combat harmul arthropods. These chemicals, however, may also affect nontarget organisms due to highly conserved endocrine systems in arthropods. Due to the high number of potential EDCs and arthropod species in the environment, it is not possible to perform hazard assessment for all chemical-species combinations. Better mechanistic understanding of molting disruption by different EDCs and in different taxa, and the development of universal models for arthropods in general are needed. The present study therefore employed the adverse outcome pathway (AOP) concept with the main aims of investigating the molting regulatory pathways in arthropods and evaluating a conceptual AOP for molting disruption using the aquatic crustacean *Daphnia magna*. An extensive literature survey was performed to summarize existing knowledge and develop a conceptual pathway network (CPN) for understanding the molting regulatory processes in arthropods. The conservation of key proteins involved in the regulation of molting was assessed using the SeqAPASS tool. A conceptual AOP was developed based on the CPN and a number of key toxicity pathways leading to lethal molting disruption were highlighted. The AOP was submitted to the AOPWiki (AOP #4). Experimental evaluation using *D. magna* showed that four known insect EcR agonists were able to bind to the *D. magna* EcR. The *in vivo* study revealed an apparent increase and subsequent decrease of the ecdysteroid titer required for a succesful molt cycle in *D. magna*, which complied with knowledge from insects and other crustaceans. Exposure of *D. magna* to the endogenous ecdysteroid 20E showed impaired molting, ovulation, feeding, cuticle structure, and increased mortality. Multiomics analysis (RNAseq, iTRAQ proteomics and lipidomics) further revealed that a number of genes, proteins and lipid metabolites were mapped to the CPN, indicating similar endocrine regulation of molting in *D. magna* compared to other arthropods. The present study has provided substantial mechanistic insights into molting regulation and disruption in arthropods and developed the first invertebrate endocrine disruption AOP to facilitate next generation hazard and risk assessment of EDCs.

24

Using endocrine disrupting parasites to inform endocrine disrupting chemicals: a molecular to population level approach

A. Ford, University of Portsmouth / Biological Sciences; S. Short, Cardiff University; Y. Guler, M. Bossus, University of Portsmouth; A. Green Etxabe, CEH Wallingford; I. Martins, CIIMAR University of Porto; S.A. Kohler, University of Portsmouth / Aquatic Biology; P. Kille, Cardiff University

Many aquatic invertebrates are prone to infections by parasites which can alter sex ratios and behavior along endocrine-mediated pathways. These parasites, despite sometimes ignored or considered an inconvenient ‘noise’ in environmental monitoring have the capacity to inform and conceptualize the impacts of endocrine disrupting chemicals. For example, incomplete feminization by parasites can sometimes leave populations with a very high prevalence of intersexuality. Intersex specimens carry of a burden of altered growth, reproduction, and immunity which can be modelled. In addition, behavior-altering parasites utilizing serotonin-mediated pathways can leave organisms with a 20-fold increased likelihood of predation. The molecular, individual and population-level impacts of these parasites have been well characterized within the fields of ecological research. Here we provide a body of research into crustaceans which have feminizing and behavioral altering parasites that are being used to determine adverse outcomes (AOs) for reproductive and neurological endocrine disruption using transcriptomic and population modeling approaches. Using the amphipod (*Echinogammarus marinus*) as a model, we have determined the differential gene expression of specimens with parasite and non-parasite mediated intersexuality. We highlight that existing vertebrate biomarkers of feminization should not be applied to crustaceans, as orthologous genes are not induced in feminized amphipods. Furthermore, in contrast to vertebrates, where feminization and intersexuality are often associated with deleterious de-masculinization, we find males maintain masculinity even when unambiguously feminized. This reveals a considerable regulatory separation of the gene pathways responsible for male and female characteristics and demonstrates that evidence of feminization (even if detected with appropriate biomarkers) is not a proxy for de-masculinization in crustaceans. Moreover, we have used behavioral and serotonin altering parasites to develop behavioral tests to inform serotonin altering pollutants such as antidepressants. These intern have revealed insightful biological pathways using high-throughput sequencing approaches. All these reproductive and behavioral costs have been used to parametrize a dynamic deterministic population model over 10-year scenarios striking effects on long-term populations.

Measuring the Sustainability of Circular Economies: the Potential of LCA

25

Improving the effect of circular procurement: Three aspects of measuring sustainability impact

M. Zijp, J.T. Quik, RIVM / DMG; E. De Valk, E. Dekker, National Institute for Public Health and the Environment RIVM; L. Posthuma, RIVM / Centre for Sustainability, Environment and Health

‘He who pays the piper calls the tune”. The Dutch government spends 73 billion Euro per year, while at the EU level the amount totals to 1.8 trillion Euro per year. This large public spending power is strategically supportive to stimulate sustainable procurement, forwarding policy goals such as increased resource efficiency through a circular economy and climate change reduction. Sustainable procurement is already practiced for more than 15 years in the Netherlands and other EU countries a-like. And circular procurement, which is one form of sustainable procurement, attention. For circular procurement sustainability impact measurement has three applications during the procurement procedure. These are 1) potential impact assessment in order to determine for which products or services circular procurement (which is often an investment in terms of capacity) is most beneficial; 2) comparative impact assessment, to choose between optional products and services; 3) to evaluate the actual impact of the sustainable and circular procurement during and after contract management and stir for further improvement. Life Cycle Analysis (LCA) plays a role in all three aspects, but different with regards to scope, requirements for the inventory, and quality assessment. In 2018 the actual effect of this policy instrument, sustainable procurement, among which circular procurement, was evaluated in the Netherlands for 16 product groups. 150 procurements where analysed, of which 117 showed to take sustainability into account. The contracting authorities of these procurements were contacted to check if the finally supplied products or services where indeed more sustainable than the market average. LCA was used to estimate the difference between the supplied and the market average. This difference is an indication of the effect of sustainable procurement, which was e.g. expressed in CO_2 equivalents 5 megaton over the whole contracts of the products and services supplied. Hence, public procurement has great potential to contribute to sustainable transitions, like toward a more circular economy. By measuring the actual impact, lessons can be learned for realising this potential.

26

Interpreting LCA results from a life cycle and circular economy perspective: Application of the Life Cycle Gap-Analysis

M. Dieterle, Fraunhofer Institute for Chemical Technology ICT / Environmental Engineering; T. Viere, Pforzheim University / Institute for Industrial Ecology

The interpretation of LCA results from a LCG-A perspective allows to analyze the consequences of product innovations & new technologies with regard to both, the vision of circular economies and the actual consequences for current life cycle systems. In other words: the LCG-A visualizes the distance between an ideal closed system and the status quo in a simplified way, without ignoring trade-offs across the entire life cycle. LCG-A thereby supports various stakeholders from research and development, industry and politics by analyzing the consequences of their ideas and decisions for individual products. The application of the LCG-A is demonstrated based on a virtual case study of a lithium-ion (li-ion) battery for e-mobility.

27

Using relative market prices to better evaluate the environmental benefits of the circular economy

D. Schrijvers, ISM / ISM CyVi; P. Loubet, CyVi-ISM / ISM CyVi; G.

Sonnemann, University of Bordeaux / ISM CyVi
To verify whether recycling or other Circular Economy strategies are environmentally beneficial, we need to compare the life cycle impacts of the CE activity with a scenario in which this activity is not implemented. Functional comparability is a key issue in any comparative LCA – especially comparing a recycled (or reused, remanufactured, etc.) product with a primary alternative – but also in the modelling of substitution related to the use or the supply of a recycled material. A general assumption in LCA is that a recycled product is 1:1 comparable to its primary equivalent. However, this assumption is often inaccurate due to differences in quality or even image. Furthermore, changes in material properties can cause that the recycled material is competing with a primary material of a completely different nature. We propose to use the relative market price between the recycled product and the substituted primary product (A) as an indicator for functional comparability. If the products have the same price (i.e. $A = 1$), the products are fully comparable, and substitution could be modeled according to the end-of-life recycling method. A different price (i.e. $A \neq 1$) could indicate that the recycled product substitutes a product in a different market segment due to a changed functionality, quality, or a different image. In this case, a closer substitute could be identified in a different market segment. Alternatively, the use of the recycled product could lead to downstream drawbacks and/or benefits, which should be integrated both into the calculation of the market-price ratio and into the life cycle inventory. Finally, if the user of the recycled product experiences a financial benefit (i.e. $A < 1$), the demand for the recycled product is (partly) constrained, which is especially relevant in a consequential LCA. The latter implies that there is a surplus of the material and substitution is (partially) modelled by avoided or additional waste treatment. This approach enables to make two product systems more comparable by considering realistic substitutes and downstream effects of using a recycled product. The market-price ratio A can be easily integrated into the "Circular Footprint Formula" of the Product Environmental Footprint Guide of the European Commission to better model substitution in an LCA. Finally, this approach provides the perspective to put a price on externalities, which would improve the representation of factor A.

28
Quantifying net environmental and economic benefits of food waste prevention actions
V. De Laurentis; C. Caldeira, EC JRC / Directorate D Sustainable Resources, Bio-Economy Unit; T. Sinkko; S. Sala, European Commission - Joint Research Centre / Bioeconomy unit
A methodology to evaluate the effectiveness of food waste prevention actions based on Life Cycle Assessment (LCA) and cost benefit analysis is presented. This enables to quantify the net environmental benefits of an action by considering three components: (i) the environmental impact embedded in the avoided food waste up to the stage of the supply chain where the food waste is diverted, (ii) the environmental impact associated with the waste treatment of the avoided food waste and (iii) the environmental burden of the action implementation. Similarly, a cost benefit analysis is performed considering: (i) the cost of the food items saved, (ii) the cost of the avoided waste treatment and (iii) the cost of the action implementation. Following this approach, a tool was developed to enable users (mainly non-LCA experts) to perform the evaluation of a specific food waste prevention action by introducing the following information: the amounts and types of food items diverted from waste, the stage of the supply chain at which the food waste is avoided, the country where the action takes place, the type of waste treatment that would have been used had the waste been generated, the resources used in implementing the action and the overall cost of the action. An example of application of the methodology developed and the related tool is provided, by quantifying the environmental and economic benefits of an existing food waste prevention action. The influence of some of the action parameters over the results are tested through a sensitivity analysis, to identify the most relevant aspects to consider when designing an action in order to maximise its impact in terms of environmental and/or economic gains. The adoption of a life cycle approach minimizes the risk of burden shifting (i.e. by identifying situations in which the prevention action presents a burden on the environment that outweighs the benefits achieved) and can support in the design of effective food waste prevention actions. Finally, the results provided by the tool can be used to communicate the positive impact achieved through an action.

29
Life Cycle Assessment of asphalt pavements containing plastic waste as secondary raw material
F. Rosa, University of Milano-Bicocca / Department of Earth and Environmental Sciences; G. Magatti, University of degli Studi di Milano Bicocca; M. Perucca, Project HUB 360; P. Mantecca, University of Milano - Bicocca / Department of Earth and Environmental Sciences
In Europe, in the last decade, an increasingly share and quantity of post-consumer plastic waste has been sent to recycling, the 31.1% of all plastic waste collected. Nevertheless, most of what is collected is still sent to landfill or energy recovery and even a part of plastic waste supposed to be recycled is incinerated. Therefore, to avoid the loss of potential secondary raw materials, research should explore new sustainable recycling paths, according to the circular economy approach. One of this path can be the utilisation in the asphalt mixture of plastic waste otherwise destined to incineration, in order to improve the performance and thus lifespan of asphalt pavements. The present study uses the LCA methodology to assess a new process, developed to produce an asphalt that contains a super-modifier made out of recycled plastic, which improves the asphalt performance. The main goal is to quantify the environmental impacts of the new and the conventional processes and to compare them, focusing on the Italian context. The evaluation encompasses the asphalt mixture production process, from raw material extraction/collection to the production of asphalt mixture, and, besides the conventional flows (aggregates, bitumen and reclaimed asphalt pavement), it includes the additional flow of plastic waste used to produce the super-modifier. The functional unit was defined as one kilometre of extra-urban road; impacts are also expressed in terms of performance, referring to ESALs (Equivalent Single Axle Load). Preliminary results of the ongoing analysis shows that, for all the impacts categories of both CML2001 and Impacts ILCD/PEF recommendation impact assessment methods, the environmental impacts of the asphalt containing the super-modifier is lower than the conventional one, considering also the estimated lifespan related to the performance improvement. At this stage, the assessment indicates that the use of plastic waste as an ingredient in the asphalt mixture is able to enhance the structural performance while reducing the environmental impacts. The inclusion of the phases following the production process, namely road construction maintenance and EoL, will represent the next step of the analysis and allow a more accurate and complete assessment.

Target and NonTarget Mass Spectrometry for Human and Environmental Exposure Assessment (I)

31
Complementary methods for extending chemical space coverage using EPA's Non-Target Analysis Collaborative Trial mixtures
R. Singh, University of Luxembourg / Office of Research and Development National Exposure Research Laboratory; A. Chao, Student Contractor at US Environmental Protection Agency / Office of Research and Development National Exposure Research Laboratory; X.R. Xia, North Carolina State University / CCTRP/CVM; D. Shea, Statera Environmental, Inc.; J.R. Sobus, US EPA / Office of Research and Development National Exposure Research Laboratory; E. Schymanski, University of Luxembourg / Luxembourg Centre for Systems Biomedicine (LCSB); E.M. Ulrich, U.S. Environmental Protection Agency / Office of Research and Development National Exposure Research Laboratory
The EPA's Non-Targeted Analysis Collaborative Trial (ENTACT) was designed, in part, to characterize current methodological strengths and weaknesses and enables participants to identify knowledge gaps in their analysis workflow. Composed of 1269 unique ToxCast chemicals, ENTACT samples comprise 10 mixtures (numbered 499 to 508) of varying complexity in terms analyte number and presence of isomers and/or isobars. These mixtures were analysed using hydrophilic interaction chromatography (HILIC) and reversed phase (RP) chromatography with a quadrupole time-of-flight mass spectrometer to investigate how chromatography affects analyte detection. In mixture 505, with 365 total analytes, 13 of 14 highly polar compounds (negative log K_{OW}) were not observed in RP (+ESI) but showed a marked increase in ionization efficiency (300 to 2000% improvement in ion count), and improved retention in HILIC. On the contrary, analytes like 1,1,3-trimethyl-2-thiourea and acetazolamide (log K_{OW}= -0.09 and -0.37, respectively) were observed in RP alone. Further analysis of the mixtures was performed with atmospheric pressure chemical ionization (APCI) and electrospray ionization (ESI) connected to an Orbitrap mass spectrometer; 136 compounds ionized exclusively in APCI while 192 ionized exclusively in ESI. In total 540 unique compounds were observed in both ionization modes. Cheminformatic fingerprinting was performed to determine if functional group trends may help predict whether a molecule will ionize in APCI or ESI. For example, molecules containing the following substructure groups: ring: hetero_[6]_N_triazine_generic, ring: hetero_[6]_N_triazine_(1_3_5-), bond: CN_amine_sec-NH_aromatic_aliphatic, bond: CN_amine_aromatic_generic preferentially ionize in APCI. These results can be used to predict the ionization behaviour for untested chemicals to improve the chances of successful detection and can also provide further evidence to identify unknown chemicals. In addition, adjustments to the spectral processing software RMassBank during the ENTACT trial further revealed that organometallic species should be considered in non-target studies using LC-HRMS. Taking both chromatographic and ionization approaches together, it is demonstrated that chemical space coverage is improved using complementary approaches. We conclude that HILIC should be used to complement RP instead of as an alternative. In the same manner, APCI should also be used in conjunction with ESI to expand coverage.

32

Why we can't cover industrial chemicals in mass spectrometry screening, and what to do about it

S.C. Fischer, Swedish Chemicals Agency / Development of Leislation and Other Instruments

A traditional non-target screening of an environmental sample (e.g. waste water) normally ends up in a surprisingly few industrial chemicals. The Swedish Chemicals Agency (KemI) have therefore started up a collaboration with analytical reseach laboratories to found out the reasons and what to do about it. One observtion made is that current reference libraries for identifcation are not god enough for identification of industrial chemicals. One reason for this may be that chemical identity and structure data are mainly stored in regulatory databases with limited public access. To test this hypothesis KemI created a suspect list chemicals in commerce according to our different regulatory databases, called KemI Market list. The list contains more than 30.000 susbtances. The original list contains CAS number, chemical name and monoisotopic mass. Two prioritisation score where added to support the prioritisation among all candidates. One on the probability of a correct match, based on use pattern (*Exposure Score*), and one on hazard based on the Hazard classification system CLP (*Hazard Score*). The database matching (against adduct corrected m/z data) was made at KemI. KemI made a primary prioritisation on the probability and the regulatory concern, and return the result to the laboratory for futher identification. The results show that the number of identified industrial chemicals increase. An other limitation observed is that industrial chemicals in regulatory databases normally are identified with CAS numbers. CAS numbers are not always related to a specific structure. This is especially common for industrial chemicals. This make it difficult for a authority to use CAS numbers to found the souce in the society for an identified chemical. The over all conclusion is that non-target screening for regulatory purposes demands better communication and further standardisation.

33

Quality assurance and quality control of non-target screening of emerging contaminants in human urine by LC-HRMS

N. Caballero, C. Gys, P. Vervliet, G. Malarvannan, A. Covaci, University of Antwerp / Toxicological Center

The concept of contaminants of emerging concern (CECs) refers to compounds that are not (yet) included in monitoring programs because they are new or their presence in the environment has not been elucidated or understood. However, they may have the potential to exhibit toxicity in humans and wildlife. The impacts of human exposure to mixtures of chemicals are poorly understood, because biomonitoring campaigns do not include CECs. Therefore, there is an urgent need to establish a set of representative biomarkers to assess the human exposure to mixtures of CECs. Human urine is a complex matrix and the expected concentration for most of the CECs is at trace levels. In addition, presumably many types of contaminants are metabolized through different pathways and (partially) excreted through the urine. Non-target screening analysis of human urine samples by high resolution mass-spectrometry is able to provide an overview of the presence of CECs in the population. However, despite the attractive features of this novel strategy, it is facing a lack of harmonized methods that would permit obtaining comparable and high quality results. Quality assurance(QA) is defined as a set of activities or procedures which are adopted in a laboratory to ensure that all quality requirements will be fulfilled. Meanwhile, quality control (QC) refers to operational techniques and activities that are used to fulfill requirements for quality. To facilitate the development of reliable and comparable non-target/suspect screening workflows for the assessment of CECs in human urine by liquid chromatography coupled with high resolution mass spectrometry (LC-HRMS), we will further develop a generic QA/QC framework. The achievement an actual and representative fingerprint of CECs in human urine is a challenge that requires the establishment of the proper QA/QC for each individual step of the workflow. Although the establishment of a detailed list of QA/QC represents a good starting point to get to a harmonized approach of non-target/suspect screening methodologies in human urine analysis. However, more effort in this direction is still needed owing to the premature status of the major workflows in this field.

34

Improving Confidence for Phthalate Metabolite Identification by Fragmenention Pathways in LC-HRMS Based Non-Targeted Screening of Human Urines

Y. Feng, Z. Guo, Health Canada; J. Wang, Chongqing University; Y. Li, S. Huang, Health Canada

Humans are exposed to thousands of synthetic chemicals such as plasticizers that are used in many commercial products. Targeted monitoring methods using gas/liquid chromatography – mass spectrometry are sensitive ways to provide quantitative information in surveillance of well-known chemicals in exposure science, but only a small portion of chemicals in commerce have ever been monitored by this technique. Top on hundreds of new chemicals created from industries every day, the transformation of legacy compounds under environmental conditions can also produce thousands of unknown new compounds. With growing interest in causes of human diseases from exposure to contaminants in the environment and the needs of many governments to evaluate exposure risks to emerging substances and new chemicals to ensure human health, non-targeted screening methods using high-resolution mass spectrometers have become important in suspect-screening and identification of unknown metabolites in human biofluids as exposure biomarkers of emerging contaminants for risk assessment. While workflows have been developed for these methods, high-throughput database match for suspects and structure elucidation for real unknowns in complex matrices are still challenging. Especially, the lack of first-order MSMS fragment spectra from reference compounds impedes unambiguous assignment of unknown metabolites in human samples. The fragmentation pathways in MS/MS scan from the same group chemicals with similar structural skeletons are considered to be promising tools to fill this gap with the objective of increasing the identification confidence for unknown metabolites of certain group of chemicals. In this presentation, new workflows have been established to improve the identification of unknown compounds derived from LC-HRMS-based non-targeted screening analysis in both full-scan and auto-MSMS scan modes. Different fragmentation pathways and their fragmentation patterns are compared on identification confidence of unknown metabolites. The specific fragment ions from the same structural skeleton in the same group have been applied to increase the confidence of unknown metabolite identification. The performance of the structural identification workflow has been tested and validated in groups of phthalate metabolites in human urine samples. The fragmentation pathway strategy greatly decreased the amount of false positives in screening process.

Hundreds of Unrecognized Halogenated Contaminants Discovered in Polar Bear Serum

Y. Liu, University of Alberta / Laboratory Medicine and Pathology; E. Richardson, Environment and Climate Change Canada / Wildlife Research Divsion Science and Technology Branch; A.E. Derocher, University of Alberta / Department of Biological Sciences; N. Lunn, Environment and Climate Change Canada / Wildlife Research Divsion Science and Technology Branch; H. Lehmler, The University of Iowa / Occupational and Environmental Health; X. Li, University of Iowa / Dept Occupational and Environmental Health; Y. Zhang, University of Alberta; J. Cui, L. Cheng, University of Washington; J.W. Martin, University of Alberta / Department of Environmental Science and Analytical Chemistry ACES and Science for Life Laboratory

Exposure of polar bears (*Ursus maritimus*) to persistent organic pollutants was discovered in the 1970s, but recent evidence suggests the presence of unknown toxic chemicals in their blood. Protein and phospholipid depleted serum was stirred with polyethersulfone capillaries to extract a broad range of analytes, and nontarget mass spectrometry with “fragmentation flagging” was used for detection. Hundreds of analytes were discovered belonging to 13 classes, including novel polychlorinated biphenyl (PCB) metabolites and many fluorinated or chlorinated substances not previously detected. All analytes were detected in the oldest (mid-1980s) archived polar bear serum from Hudson Bay and Beaufort Sea, and all fluorinated classes showed increasing trends. A mouse experiment confirmed the novel PCB metabolites, suggesting that these could be widespread in mammals. Historical exposure and toxic risk has been underestimated, and these halogenated contaminants pose uncertain risks to this threatened species.

36

Identification of bioaccumulative organic contaminants along the aquatic foodweb using high-resolution mass spectrometry

N. Creusot, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Chemistry; k. Huba, Eawag Swiss federal Institute of Aquatic Science and Technology; B.J. Ferrari, Swiss Centre for Applied Ecotoxicology; N. Chèvre, University of Lausanne / Faculty of Geosciences and Environment; J. Hollender, Eawag / Environmental Chemistry

Aquatic organisms are exposed to mixtures of thousands of chemicals. Among them, some legacy contaminants (PCBs, etc.) are known to bioaccumulate and biomagnify along the trophic chain raising risk for wildlife and human. However, the actual exposure of aquatic organisms to more emerging contaminants remains scarce while exposure studies mainly focused on surface water compartment that not reflect the actual internal dose. Therefore, it appears relevant to get a more comprehensive picture of the actual mixtures to what aquatic organisms are exposed. In this context, this study aims to implement and evaluate an High Resolution Mass Spectrometry (HRMS)-based strategy to identify chemicals that bioaccumulate and biomagnify in aquatic organisms. To this end, sediment, biofilm, leave, macroinvertebrates and fish samples extracted by QuEChERS were analysed by using high performance liquid chromatography coupled with electrospray to a QExactive HRMS detector (ThermoScientific). HRMS analysis consisted of data dependent acquisition (DIA) in positive mode allowing to get merged MS2 scans. First, these data were evaluated under Trace-Finder 4.1® through the comparison of our experimental data to a home made database based on the accurate mass, retention time, isotopic pattern, and MS2 scans when available. From the initial list of 359 chemicals with exact mass hits, data dependent acquisition (DDA) acquired MS2 spectra were obtained for 145 candidates allowing to confirm 56 of them that were quantified by using internal calibration. Among them, biocides, fungicides and herbicides were the more widely detected along the trophic chain. Then, DIA data were also processed for suspect/non-target screening under Compound discover 2.1® From the 503 915 identified features, filtering (area, background, predicted composition and mass list match) allowed to reduce the list to 1200 features on the basis of a Norman mass list (17500 chemicals). Hierarchical clustering analysis further allowed to identify a cluster of 20 candidates with increasing area along the trophic chain and to define an inclusion list of candidates for additional MS2 acquisition that is ongoing. Our results provide a proof of concept for the implementation of HRMS-based strategies to fill the gap of knowledge about exposure of organisms to emerging contaminants. Such strategy could be the way to identify relevant contaminants for investigating their fate into organism and along the trophic chain.

Ecosystem Services: Progress, Case Studies and Reflections

37
European Assessment and management of risks to ecosystem services: Reflections
S.E. Apitz, SEA Environmental Decisions Ltd; L. Maltby, The University of Sheffield / Dpt. of Animal & Plant Sciences
The benefits which flow from natural capital, termed ecosystem services (ES), are under threat from habitat loss, climate change, invasive species, over-exploitation and pollution. At the same time they are increasingly the focus of environmental policy. Among the top 10 research questions identified by the SETAC Europe Horizon Scanning Project was “Biodiversity and ecosystem services: What are we trying to protect, where, when, why, and how?” An ES approach has been used to frame specific protection goals for ecological risk assessment (ERA) and the inclusion of ES into the life cycle impact assessment (LCA) framework is a current activity in the LCA community. ES are also being used to frame broader sustainability, cost-benefit and stakeholder engagement. It is therefore an opportune time to bring the ERA and holistic assessment communities together. An objective of the EU 7th Environment Action Programme is ‘to protect, conserve and enhance Europe's natural capital’ and the 2020 Biodiversity Strategy has a target of ‘halting the loss of biodiversity and the degradation of ecosystem services in the EU by 2020’. Do we, however, have sufficient knowledge and understanding to assess, predict and manage the effects of anthropogenic activities on ES delivery in multifunctional landscapes that are often exposed to multiple pressures, and are the monitoring, regulatory and decision frameworks that have developed over decades fit for purpose as we seek to apply this evolving knowledge? Assessing and managing the risks that stressors, often introduced as people seek to obtain selected services from land- and waterscapes, pose to the sustainable delivery of these and other ES is a transdisciplinary challenge requiring new approaches to communication and collaboration. A recent SETAC Europe special session explored how close we are to adopting an ES approach to assessing and managing environmental risk from anthropogenic stressors. It drew on the findings of a series of SETAC-Europe sponsored workshops (**C**hemicals: **A**ssessment of **R**isks to **E**cosystem **S**ervices) and built on the recent work by EFSA and ECETOC in using ES approaches to develop specific protection goals and the outcomes of the joint ESA-SETAC Pellston workshop Ecosystem Services, Environmental Stressors and Decision Making. Thus, it reviewed the state of the practice for the use of ES (primarily) in Europe, for prospective risk assessment, chemicals regulation, retrospective risk assessment (also termed forensic ecology), remediation and restoration. This paper will summarize key points, focusing on progress, opportunities, gaps and challenges, with a focus on case studies, underlying assumptions, and the relationship with ES, sustainability and LCA thinking.

38
Building on the LCA experience to initiate a standardization process for ecosystem services
S. Quatrini, ETH Zurich (CH) / Environmental Systems Science; B. Rugani, Luxembourg Institute of Science and Technology (LIST) / Environmental Research & Innovation (ERIN); L. Inostroza, Ruhr Universitat Bochum
The demand for rigorous ecosystem services (ES) assessment approaches is tremendously growing. This mainly comes from a broad community of ES practitioners other than researchers, among which public and private sector investors, multilateral and intergovernmental authorities, regulators, landowners and land users, which require best-in-class, customized and harmonized standard monitoring and management practices, instruments and guidelines to systematically incorporate ES considerations in their decision-making processes. Channelling ES knowledge into policy and decision-making practice further requires the harmonization of definitions, the standardization of classification processes and the streamlining of methodological and epistemological properties of ES accounting, quantification, valuation and mapping approaches. Recent efforts to combine the ES concept and assessment methodologies with the life cycle assessment (LCA) method show that examples and avenues to overcome the current taxonomic and methodological gaps exist. LCA is a widespread methodology standardized by ISO 14040:2006, which is hugely applied around the world by thousands of industrial actors and decision makers across numerous economic sectors and products. LCA allows converting a variety of environmental stressors into a set of specific integrated indicators of environmental impact. This facilitates impact monitoring and communication to stakeholders. It also enables the comparison of environmental performance, the development of labels and certification schemes, as well as implementation of environmental protection policies, regulations and technological improvements. In this presentation, we discuss options and challenges to advance the application of ES science and the potential for the ES community to learn from the LCA experience in ISO-level standardization in order to promote methodological harmonization. Our objective is to initiate a dialogue and cross-fertilization exercise between the two research communities that could open up opportunities for collaboration in the development of ES management standards. <br clear="all" />

39
Soil Quality and related Ecosystem Services in Life Cycle Assessment
H. Stichnothe, Thünen Institute / Agricultural Technology
Soils are unquestionably an essential component of the global ecosystem and high quality functional soil is important for the supply of ecosystem services such as, providing biomass and regulating climate. Therefore, maintaining healthy and functioning soils is a fundamental requirement for globally sustainable production chains, particularly those related to agricultural and forestry based systems. The related land use and land use change (LULUC) are key human stressors that can affect the quality of soil and hence it’s functioning and delivery of ecosystem services. A task force working within Life Cycle Initiative hosted by United Nations (UN) environment has been working for the last two years to recommend suitable indicators which can be used within a Life Cycle Assessment framework (LCA) which can be used for soil quality and its associated ecosystem services. The dynamics of soil organic carbon (SOC) accumulation and loss are a function of soil type, climate, land-use type, and in particular land management (occupation and change), which makes it a good proxy for damages to ecosystem services. Therefore, as changes in soil organic carbon (ΔSOC) stock is interim, the task force recommends its use as an indicator of soil quality as it is a good integrative indicator of soil functions. Further suggestions by the task force are that soil loss is recommended as a separate indicator linked to natural resources, to address erosion impacts. Additional issues identified by the task force have been the need for improving the representation of forestry and permanent crops.

Biogeochemistry and Fate of Organic Pollutants in Aquatic Systems (I)

41
Assessing the contribution of biotransformation to the fate of 40 micropollutants in a lake ecosystem
A. Chalifour, N. Hoch, Eawag Swiss federal Institute of Aquatic Science and Technology / Environmental Chemistry; F. Pomati, Eawag Swiss Federal Institute of Aquatic Science and Technology / Aquatic Ecology; K. Fenner, Eawag Swiss federal Institute of Aquatic Science and Technology / Department of Environmental Chemistry
Organic micropollutants (MPs) such as pesticides and pharmaceuticals are consistently measured at the ng/L to μg/L level in freshwaters. Studies on lakes such as Greifensee in Switzerland have attempted to measure the contribution of different dissipation pathways to the mass balance of several pharmaceuticals over consecutives months. However, the contribution of biotransformation to the overall dissipation of MPs has rarely been quantitatively elucidated. This project aimed to fill this knowledge gap by conducting biotransformation experiments during several, ecologically differing phases of plankton succession in Greifensee, and at different depths. Grab samples of Greifensee water were collected during 6 sampling campaigns extending from April 2018 to October 2018. Concentrations of 40 MPs were measured at 5 different depths of Greifensee, and the original water from 3 m and 6 m (filtered at 80 μm to remove zooplankton) was spiked with the mix of 40 selected MP, each at an initial concentration of 100 ng/L, and used for biotransformation experiments as batch cultures in an environmental chamber. MP concentrations were measured at 8 different time points over the course of 3 weeks using LC-MS. No biotransformation was observed for caffeine and other conservative compounds. Moreover, compounds known to be rather efficiently phototransformed, e.g., diclofenac, were found to behave conservatively under the low light conditions used. In contrast, for compounds such as valsartan, biotransformation was observed during some experiments and biotransformation rate constants could be calculated. The kinetics obtained from the batch experiments helped to understand the observed concentration changes measured in Greifensee. For example, MPs such as valsartan and sulfamethoxazole showed strongly deviating seasonal concentration profiles, even at depths clearly extending into the hypolimnion. Their concentrations were lowest when the biomass of microorganisms was particularly high in Greifensee (i.e., late summer), suggesting that these compounds might undergo

biotransformation by the native microorganisms. By combining biotransformation rate constants measured in laboratory batch cultures with lake mass balance considerations, we were able to confirm the importance of biotransformation relative to phototransformation for the fate of several MPs in a lake ecosystem.

42

Spatial and seasonal distribution of organic micropollutants in Lake Mälaren, Sweden

A. Rehrl, Swedish University of Agricultural Science / Department for Aquatic Sciences and Assessment, SLU; S.J. Köhler, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; L. Ahrens, Swedish University of Agricultural Sciences SLU / Dept. of Aquatic Sciences and Assessment; O. Golovko, Swedish University of Agricultural Sciences (SLU) / Department of Aquatic Sciences and Assessment

The main objective of this study was to investigate the occurrence and fate of organic micropollutants (OMPs) in surface water in Lake Mälaren over one year and assess their seasonal variations and spatial (vertical and horizontal) distribution. The water samples were enriched with solid phase extraction (SPE) and subsequently analyzed by ultra-high pressure liquid chromatography tandem mass spectrometry (UPLC-MS/MS). The applied multi-residue method comprised 122 organic micropollutants (OMPs) covering a wide range of physico-chemical properties that were chosen due to their high annual usage rates and continuing major concerns regarding their adverse effects on humans and aquatic organisms. In total, 50 OMPs were detected at least once above limit of quantification (LOQ). The highest detected concentration was found for lamotrigine with 140 ng/L. The locations Ekoln and Västeråsfjärden were identified to be most affected by OMPs pollution. Seasonal patterns were observed for numerous OMPs indicating varying pollution sources and compound specific distribution and degradation processes of OMPs in the aquatic environment. Only a few vertical distribution patterns and concentration gradients were observed, for instance, the deepest sampling depth (30 m) from Ekoln showed considerable higher concentrations than the upper sampling depths in February. A strong positive correlation was found for carbamazepine and lamotrigine, but also for other OMPs indicating similar pollution sources or transport and fate processes. Two industrial chemicals, tolyltriazole and tris(2-butoxylethyl)phosphate showed very good analytical performance parameters and were detected frequently and it is recommended to incorporate these compounds more regularly in future analysis. To the best of our knowledge, this study is the first one to report the occurrence and distribution of OMPs representing such wide physico-chemical properties, including industrial chemicals, in a Swedish lake.

43

Analysing biotransformation kinetics of micropollutants across different water-sediment test systems

C. Seller, H. Singer, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Environmental Chemistry; M. Honti, Budapest University of Technology and Economics; K. Fenner, Eawag Swiss federal Institute of Aquatic Science and Technology / Department of Environmental Chemistry

To date, it remains impossible to fully prevent bioactive and therefore potentially harmful substances (i.e. pharmaceuticals and pesticides) from entering the aquatic environment. Some pathways through which those pollutants reach surface waters are hardly controllable such as agricultural runoff. The manufacturing and use of chemicals, however, could be controlled more easily. From the regulatory side, the OECD 308/ 309 guidelines represent the most relevant simulation studies to assess persistence of chemicals that may enter surface waters. There is consensus that transformation kinetics observed in those OECD studies do not directly project into compound behavior in the environment. A thorough understanding of relevant system-specific differences that govern the transferability from laboratory to field systems is still missing. This work targets the connection between persistence measured in different regulatory water-sediment test systems and for different types of sediment by investigating a persistence evaluation concept that employs a substance-specific bioavailability-corrected and biomass-normalized second-order biotransformation rate constant (k'_{bio}). Various OECD 308 and 309-type experiments were set up and the fate of 38 substances, mostly pharmaceuticals and pesticides, was followed. The measured concentration-time series and other parameters such as bacterial abundance within the test systems were used to feed an inverse modelling framework estimating transformation rate constants. The results of the model fitting suggest that k'_{bio} may be a generally valid parameter for quantifying biotransformation across different water-sediment systems and a valid indicator of a substance's aerobic biotransformation potential. The system-independency of k'_{bio} makes it a promising future tool to translate transformation kinetics from the laboratory to the field.

Long-term mercury records in a boreal lake: lake processing and the role of organic matter

H. de Wit, NIVA - Norwegian Institute for Water Research; H. Braaten, Norwegian Institute for Water Research NIVA; C.B. Gundersen, P. Krzeminski, NIVA Norwegian Institute for Water Research; R.D. Vogt, University of Oslo / Department of Chemistry

Fish in northern humic lakes often have mercury (Hg) levels higher than advisories for human consumption. The Hg in these lakes is primarily from current and legacy long-range transported air pollution sources. Foodweb exposure to aquatic Hg is regulated by dissolved organic matter (DOM) as a transportation vector, source of energy, and regulator of bioavailability. Long-term records of Hg in inlets, lakes, and outlet enable understanding of the role of catchments and lakes in regulation of foodweb exposure to Hg. The inlet and outlet streams of lake Langtjern in southern Norway have been monitored for water chemistry and hydrology since the 1970s and since 2004, for MeHg and total Hg (monthly since May 2008). Langtjern is oligotrophic, recovering from acid deposition and browning. The ratio of mean annual lateral catchment Hg inputs and direct atmospheric deposition of Hg to the lake is circa 8:1. Long-term mean concentrations of HgT and MeHg in the outlet are 3.5 and 0.08 ng/L, respectively, and show no changes over time. However, the ratio of MeHg to HgT shows a significant linear decrease ($p< 0.05$). Annual patterns in inlet and outlet concentrations are similar, suggesting that lake processing does not have a major impact on outlet Hg dynamics, but is rather driven by catchment processes. However, the Hg:dissolved organic carbon (DOC) ratio in the outlet is significantly higher than in the inlets, an indication of lake DOC removal through in-lake processing, and redistribution of Hg to remaining DOC. Size fractionation of DOM (tangential ultrafiltration) and studies of biodegradability of size fractions (measured as O_2 consumption) indicate differences between inlet and outlet in size fractionation, biodegradability of fractionated DOM and Hg associated with the different size fractions. The smallest size fraction (2 consumption per g DOC). We suggest that the base of the aquatic foodweb in the outlet is more exposed to Hg than in the inlets, especially for organisms relying on bacteria as energy source. Bacterial consumption of easily degradable, Hg-contaminated DOM is thought to be an important pathway for Hg into the aquatic foodweb.

Investigating the micropollutant biotransformation potential of differently adapted natural stream biofilms

W.L. Desiante, Eawag Swiss Federal Institute of Aquatic Science and Technology; B. Vogler, K. Fenner, Eawag Swiss federal Institute of Aquatic Science and Technology / Department of Environmental Chemistry

Micropollutants, found in complex mixtures in the environment, can pose a risk to aquatic organisms. Stream biofilms, which consist of algae, bacteria and other microorganisms, play a key role in nutrient cycling and have been demonstrated to have a large potential to act as natural sinks for micropollutants. Exposure of stream biofilms to treated wastewater has been shown to result in increased tolerance to micropollutants, possibly due to an increased biotransformation potential of those biofilms. In our research, we want to explore the ability of differently adapted natural river biofilms to biotransform micropollutants. Thus, in spring 2017, we launched a study involving stream biofilms cultivated up- and downstream of two wastewater treatment plant outfalls, which was replicated in fall 2018. The main aim of this study was to investigate the biotransformation potential of natural river biofilms towards a large mixture of environmentally relevant micropollutants. Our experiments consisted of suspended biofilms in batch reactors with adequate controls. A mixture of 55 compounds was spiked into the reactors and concentrations were monitored over time. In general, we found a broad range of micropollutants to be biotransformed. Fourty compounds showed a concentration decrease, that, given the data from the controls, could be attributed to biotransformation. Of these, six were not consistently biotransformed between all sites. Within the 34 compounds that showed decreasing concentration patterns in all of the investigated biofilms, a variety of primary biotransformation reactions were represented, such as conjugation, substitution-type, and oxidation-type reactions. Interestingly, three of the six compounds that showed different biotransformation patterns between the investigated sites belonged to the compound class of artificial sweeteners. In particular, for these compounds, biotransformation could only be found in the downstream communities. Those findings lead to the conclusion that the respective downstream communities underwent changes that lead to an increased potential to biotransform those compounds, whereas the upstream communities did not. Thus, our studies were able to point out the relevance of stream biofilms in biotransforming micropollutants and lead to some interesting open questions regarding the origin of the increased biotransformation potential towards specific micropollutants in communities exposed to treated wastewater.

Fate of atmospheric aromatic hydrocarbons into the oligotrophic ocean

B. Gonzalez-Gaya, IMDEA Water (G84912732) / Environmental Chemistry; A. Martinez-Varela, m. vila-costa, Institute of Environmental Assessment and Water Research IDAEACSIC; P. Casal Rodríguez, IDAEA-CSIC / Environmental Chemistry; E. Cerro-G�lvez, Institute of Environmental Assessment and Water Research (IDAEA-CSIC); N. Berrojalbiz, Institute of Environmental Assessment and Water Research IDAEA CSIC / Environmental Chemistry; D. Lundin, Linnaeus University; M. Vidal, University of Barcelona; C. Mompean, Spanish Oceanography Institute; A. Bode, Spanish Oceanorgaphy Institute; B. Jimenez, IQOG-CSIC / Department of Instrumental Analysis and Environmental Chemistry; J. Dachs, IDAEA-CSIC / Environmental Chemistry

Polycyclic aromatic hydrocarbons (PAHs), and other semivolatile aromatic-like compounds (SALCs), are an important and ubiquitous fraction of organic matter in the environment which fate in the ocean remains uncharacterized. Here, we report a global assessment of the occurrence and atmosphere–ocean fluxes of 64 PAHs analyzed in paired atmospheric and seawater samples from the Atlantic, Pacific and Indian Oceans. The global atmospheric input of PAHs to the ocean is estimated at 0.09 Tg/month, four times greater than the Deepwater Horizon spill. The environmental concentrations of total SALCs were 10^2–10^3 times higher, with a relevant contribution of an aromatic unresolved complex mixture. These concentrations drive a global deposition of carbon estimated at 400 Tg C yr^{-1}, around 15% of the oceanic carbon uptake due to CO_2. Furthermore, we identify the biological pump and microbial degradation as key sinks of aromatic hydrocarbons in the oceans. Plankton and seawater samples showed lower concentrations of the hydrophobic compounds in the seawater when plankton biomass was higher, consistent with the relevance of the biological pump. However, the mass balance for the global oceans showed that settling fluxes of aromatic hydrocarbons in the water were 2 orders of magnitude lower than atmospheric deposition. These observations show the relevance of PAHs degradation processes in the oligotrophic oceans. Among different processes considered (i.e. photochemical degradation) microbial degradation appeared to be the key factor for the depletion of the bioavailable hydrocarbons. We quantified the relative abundance of PAHs-degrading genes by analyzing the frequency of the alpha and beta subunits of RHD (specific biomarkers of PAH degradation) in the public metagenomic database of the oceanographic expedition Tara Oceans. Degradation genes for PAHs were found to be ubiquitous. The several lines of evidence provided support a relevant microbial degradation of PAHs, and also relevant for the largest SALCs organic carbon pool. It has been reported that large oligotrophic oceanic regions are heterotrophic, requiring sources of allochthonous organic matter. According to this work, degradation of atmospheric inputs of aromatic compounds is quantitatively relevant for the marine carbon cycle, and could help explain the observed heterotrophy of the oligotrophic oceans.

Remediation of Contaminated Environments and Innovative Methods in Biological Strategies (I)

47

Cropping trees and fiber plants at phytomanaged sites

M. Chalot, T. JEANNIN, L. YUNG, Université de Bourgogne FrancheComté; P. Evon, P. OUAGNE, L. LABONNE, Université de Toulouse; M. LECOURT, FCBA; D. Cazaux, INOVYN France; V. PLACET, Université de Bourgogne FrancheComté

Phytomanagement-based restoration programs for contaminated soils may use woody plant species that are colonized by essential microorganisms, especially in highly stressed and nutrient-poor environments, such as TE- contaminated sites. Trees from phytomanaged sites have been proposed as a potential source of biomass for bioenergy and various energy-recovery techniques such as combustion, gasification and pyrolysis, which we have recently addressed. Within previous projects, we exploit the implementation of an integrated bioremediation option that combines poplar together with mycorrhizal fungi. We implemented 3 demonstration sites in France of 1 ha each mostly contaminated by Hg and As. Four replicate field blocks were established in February (P) and March (F) 2011 using unrooted poplar cuttings Skado (*P. trichocarpa x P. maximowiczii* section Tacahamaca) and I214 (*P. deltoides x P. nigra* sectionAigeiros). Most interestingly, 5 years after the plantation, biotic and abiotic conditions have promoted the appearance of a spontaneous herbaceous cover. In the present work, we show recent data on an on-going project (http://phytofiber.fr/), which main objective is the multi-purpose valorisation of wood and plant fibres produced on mixed-metal-contaminated soils. Despite the unfavorable soil conditions, we found that poplars performed quite well at the phytomanaged sites in terms of biomass production, that was enhanced by inoculation with symbiotic fungi. The naturally occurring nettle under poplar offered a natural source of fibers, which properties are equal to or better than those of hemp and flax, making this nettle biomass very promising for composite application.

48

Operating on bioavailability processes during bioremediation: Roles of pollutant phase exchange and microbial dispersal

J. Ortega-Calvo, Instituto de Recursos Naturales y Agrobiologia / Agroquimica y Conservacion del Suelo; R. Posada, IRNAS CSIC / Agroquimica y Conservacion del Suelo; J. Garcia, M. Cantos, Instituto de Recursos Naturales y Agrobiologia de Sevilla CSIC

This overview presentation will cover innovative strategies for a controlled enhancement of pollutant bioavailability, with the aim at reducing the execution periods (and costs) of bioremediation for the achievement of acceptable limits for risk reduction, and even reach lower end-points than currently possible. For bioavailability to be incorporated into bioremediation, three questions must be addressed: (1) how is "bioavailability" defined? (2) how should it be measured? and (3) is it possible to increase bioavailability but not environmental risk of the pollutants? In a recent review, the concepts and definitions of bioavailability of organic chemicals are examined from a risk assessment perspective (*Environ. Sci. Technol.* 49:10255-10264, 2015). The main schools of thought consider bioavailability (focusing on the aqueous or dissolved contaminant), bioaccessibility (incorporating the time for exposure), and chemical activity (determining the potential of the dissolved contaminant for biological effects). These concepts are the basis for different methodologies (desorption extraction, passive sampling and biological tests) and mechanistic studies on the different bioavailability processes (contaminant soil/sediment interactions, transport and passage across cell membrane, and biological responses such as toxic effects or biodegradation). Our group has proposed different ways to operate at different levels on these processes for a better bioremediation performance in risk reduction. The approach is relevant because in some circumstances bioremediation may even increase risk of the pollutants. The prospected risk-minimizing strategies include targeting slow-desorption pollutant fractions with (bio)surfactants (*Environ. Sci. Technol.* 45:3019-3026, 2011; *Environ. Sci. Technol.* 48:10869-10877, 2014), the localized fertilization of free-oil phases or NAPLs (*Environ. Sci. Technol.* 45:1074-1081, 2011), modulated deposition and motility of microbial degraders (*Environ. Sci. Technol.* 46:6790-6797, 2012; *Environ. Sci. Technol.* 52: 10673−10679, 2018), promotion of bioavailability with plants and root exudates (*Soil Biol. Biochem.* 57:830-840, 2013; *Environ. Sci. Technol.* 49:4498–4505, 2015), and facilitated microbial (bacterial/oomycete) interactions for the colonization of pollutant interfaces (*Environ. Sci. Technol.* 50: 7633-7640, 2016; *Environ. Sci. Technol.* 51: 11935-11942, 2017).

Role of rhizoremediation in PCB contaminated areas: remediation time estimation from greenhouse experiment data

E. Terzaghi, University of Insubria (Como) / Department of Science and High Technology, Como; G. Raspa, Sapienza University of Rome / Department of Chemical Engineering Materials and Environment; E. Zanardini, University of Insubria / DSAT; C. Morosini, University of Insubria / Department of Science and High Technology; F. Mapelli, University of Milan- DeFENS / Department of Food, Environmental and Nutritional Sciences; L. Vergani, University of Milan / DeFENS; S. Borin, DeFENS University of Milan / Department of Food, Environmental and Nutritional Sciences; S. Armiraglio, Municipality of Brescia / Museum of Natural Sciences; V.M. Sale, S. Anelli, P. Iavazzo, P. Nastasio, ERSAF; A. Di Guardo, University of Insubria / Department of Science and High Technology

In the last two decades there has been a growing interest in bioremediation technologies which use plants and microorganisms to degrade organic chemicals such as PCB in contaminated sites (rhizoremediation). Different studies have been conducted to investigate the potential of plant-microbe interactions in the remediation of organic chemical contaminated soils with respect to natural attenuation, providing useful data such degradation half-lives. Such a type of data can be used to predict soil concentration temporal trend and the time needed to achieve legal limit when using plants and their associated rhizosphere microbe to remediate contaminated sites. In the present work a greenhouse experiment was performed with an aged contaminated soil coming from a National Relevance Site (SIN) for remediation located in Northern Italy (SIN-Brescia Caffaro). The soil was characterized by high concentrations of PCB at mg/kg levels. 10 different treatments (combination of different plant species and different soil conditions) were considered together with the appropriate controls (soil without plants). Soil and plant biomass were analysed at the beginning of the experiment (t0) and 18 months after the seeding (t18). The obtained soil concentrations were used to calculate concentration reduction with time and the corresponding rhizoremediation half-lives. The rhizoremediation half-lives obtained for the most efficient treatments were used to estimate the time needed to achieve legal limit considering three different areas characterized by a high spatial variability of PCB concentrations. Geostatistical techniques were used to build up remediation time maps for the three different areas. The aims were to: 1) provide a rhizoremediation half-live dataset for PCBs, 2) evaluate the effectiveness of rhizoremediation when a complex contamination gradient is present, 3) compare the influence of natural attenuation vs. plant/microbe interactions on remediation time. This study provided an important rhizoremediation half-life dataset for PCBs referred to different plant species and soil conditions. Moreover, it showed that when a complex contamination gradient (spatial variability of concentrations, contaminant mixture, etc.) is present, rhizoremediation must be accurately implemented and fine-tuned (in terms of species to be selected, their density, etc) to account for effective remediation.

50

Characterization of a rhizosphere microbial community of a poplar-assisted bioremediation strategy applied for recovering a contaminated soil from PCBs

A. Barra Caracciolo, National Research Council / Water Research Institute; P. Grenni, National Research Council of Italy (CNR) / Water Research Institute; M. Di Lenola, National Research Council of Italy / Water Research Institute; C. Campanale, G.L. Garbini, G. Aimola, Italian National Research Council / Water Research Institute; M. Lopez, Consejo Superior de Investigaciones Científicas; A.J. Fernández González, P.J. Villadas Latorre, Consejo Superior de

Investigaciones Científicas / Departamento de Microbiología del Suelo y Sistemas Simbióticos; V. Ancona, Italian National Research Council / Water Research Institute
A poplar-assisted bioremediation strategy has been applying in a historically PCB contaminated soil located in Southern Italy. At different times, PCB concentrations were evaluated in soil samples at different depths and distance from the tree trunks of selected contaminated plots. Similarly, microbial analyses were carried out on soil samples to assess total microbial abundance, cell viability, dehydrogenase activity and the phylogenetic composition of the autochthonous microbial community. An overall improvement in soil quality in terms of a significant decrease in all PCBs investigated and increases in microbial abundance, cell viability and activity was observed. The highest microbial abundance and total nitrogen content were found in the rhizosphere. In all soil samples, the PCB values are under the Italian legislation limits in each plot considered. RNA and DNA were extracted and cDNA synthesized. The hypervariable regions V4-V5 of the 16S rRNA gene were amplified using universal primers U519F and U926R. The microbial community structure was characterized by MiSeq (Illumina). Using DNA or cDNA different information was available. *Proteobacteria* was the most abundant phylum in both DNA and cDNA samples, *Acidobacteria* and *Bacteroidetes* were more present in the rhizosphere than in the bulk soil. *Firmicutes* and *Actinobacteria* were more present in bulk than in rhizosphere soil. Significant differences were found between rhizosphere and bulk soil at different hierarchical levels. In particular some genus such as *Mesorhizobium*, *Skermanella*, *Pseudomonas*, *Stenothtrophomonas* able to degrade PCBs were found in the rhizosphere, showing the role of these bacterial populations in the contaminant removal.

51
Utilizing low-cost natural waste for the removal of pharmaceuticals from water: Mechanisms, isotherms and kinetics at low concentrations
Y. LI, Environmental Research Institute, North Highland College, University of the Highlands and Islands, Castle Street, Thurso, Caithness, KW14 7JD, UK; M.A. Taggart, Environmental Research Institute, North Highland College, University of the Highlands and Islands, Castle Street, Thurso, Caithness, Scotland KW14 7JD, UK; C. McKenzie, Forensic Drug Research Group, Centre for Anatomy and Human Identification, School of Science and Engineering, University of Dundee, Nethergate, Dundee, DD1 4HN, UK; Z. Zhang, The James Hutton Institute / Environmental & Biochemical Sciences; Y. Lu, Research Centre for Eco-Environmental Sciences, Chinese Academy of Sciences, 18 Shuangqing Road, Haidian District, Beijing, 100085, Peoples Republic of China; S. Pap, S. Gibb, Environmental Research Institute, North Highland College, University of the Highlands and Islands, Castle Street, Thurso, Caithness, KW14 7JD, UK
The presence of pharmaceuticals in the aquatic environment has been well documented and is of global concern due to their adverse impacts including antibiotic resistance. Conventional wastewater treatment processes are often not sufficient to eliminate these contaminants, and hence, the need to develop effective solutions remains. To address this challenge, sorption processes may possess certain advantages in terms of effectiveness, convenience and simplicity, however, their application is sometimes limited by high cost (e.g., activated carbon costs 700-5000 US$/ton). Alternatively, other biosorbents may offer a sustainable solution. This study evaluates the potential use of low-cost materials derived from agro- and/or industrial wastes as low-cost biosorbents for the removal of priority pharmaceuticals of legislative concern. Unlike many other studies, we do not focus on the synthesis of high cost functionalized sorbents, instead we seek to demonstrate how "waste" (without additional processing) can be used to remove pharmaceuticals at environmentally relevant, low concentrations. The performance of eleven natural low-cost biosorbents to remove 17 priority pharmaceuticals from aqueous media was investigated and the biosorption behaviour of the three most efficient materials was considered using two model compounds (diclofenac and trimethoprim): biochar (pyrolyzed from orchard prune residues), macro-algae (brown seaweed, *Fucus vesiculosus*) and wood chippings (oak tree waste). This work considers the biosorption behaviour for these quite different pharmaceuticals, considering (in depth) the mass transfer principles, kinetics, isotherms and the mechanisms involved. High removal efficiencies were achieved at low initial pharmaceutical loadings, indicating the potential for application of these biosorbents at low (i.e., environmentally relevant) pharmaceutical concentrations. These materials may thus provide a sustainable (circular economy based), low cost water treatment solution, especially in rural or semi-rural areas.

52
Use of adsorbents for accelerated bioremediation of petroleum-contaminated soils
G. Vasilyeva, E.R. Strijakova, V.S. Kondrashina, Institute of physicochemical and biological problems in soil science RAS
In spite of the evident privilege of bioremediation for petroleum-contaminated soils, application of this approach is restricted due to poor adaptation of indigenous or inoculated microorganisms and plants in the highly contaminated soils. The main goal of this presentation is to outline up-to-date level of knowledge on the use of adsorbents for bioremediation of petroleum-contaminated soils as well as to share our experience of investigations in that direction. Several long-year laboratory and out-door experiments were carried out with various types of mineral soils spiked with crude oil, diesel fuel, and spent motor oil at the initial concentrations of petroleum hydrocarbons (TPH) from 5 to 15_{mass}%. We studied the Influence of soil amendment with biopreparations (BP) based on hydrocarbon degrading microorganisms as well as with natural adsorbents of various origination (mineral, organic, and carbonized) were studied. The experimental results indicate that the maintenance of optimal hydrothermal conditions, aeration, soil pH, ratio C:N:P:K are the most important factors for successful process of bioremediation. The soil amendment with BP appeared effective only in some cases: moderately high petroleum content (from 7 to 10% TPH) or in cold climate. Additional acceleration of bioremediation can be created through soil amendment with natural adsorbents of all classes. Their optimal doses deviated from 0.2 to 9% depending on the adsorbent and form or rate of contamination. Positive influence of the adsorbents is explained: 1) by the reduction of soil toxicity to microorganisms and plants due to mostly reversible adsorption of toxic petroleum components and especially their oxidized products; 2) - reduction of soil hydrophobicity followed by improving soil porosity and water capacity; 3) – localizing water soluble components in the treated soil layer. Hereby no significant accumulation of toxic polyaromatic hydrocarbons has been detected in soil and grasses grown after soil recultivation. The research was supported by RFBR grant No16-05-00617a

From Hazard Assessment to Regulatory Risk Management Action - Approach Development for UVCBs (I)

53
What makes it challenging to regulate UVCBs ? – A perspective from regulatory authorities on how to regulate in an effective and proportionate manner multi-constituent and UVCBs
C. Tissier, ECHA-European Chemicals Agency / Risk Management; J. de Knecht, RIVM / Environment Health and Safety Division; R. Cesnaitis, European Chemicals Agency; P. Lepper, ECHA-European Chemicals Agency / D.2 Classification and Prioritisation; M. Sobanska, European Chemical Agency
Environmental hazard assessment (classification, risk assessment (PNEC), PBT assessment) together with information on uses and potential for releases and exposure is the starting point for authorities to initiate regulatory risk management actions. Any decision to start a regulatory action implies some level of certainty on the hazard or risk identified. It is also important to have a clear knowledge on the composition of the substance to be regulated so that industry is able to fulfil its obligations and authorities to enforce the regulatory measures. In comparison to mono-constituent substances, the environmental hazard and risk assessment of substances of Unknown or Variable composition, Complex reaction products or Biological materials (UVCBs), can be more challenging, because (1) the number of constituents may be large, (2) the composition (partially) unknown and/or (3) variable (due to e.g., seasonal and temporal variation in sourcing of raw materials). Those specificities make it very challenging, if not impossible, to address the hazard properties and risks of those substances. Consequently, for UVCBs a different test strategy and a more weight of evidence approach is followed to assess the hazard. Indeed, testing the whole substance does often not provide information on the properties of individual constituents. Furthermore, the composition of test solution might be different from the composition of the substance added or from the environmentally relevant composition. On the other hand, when constituents are structurally similar, it may also not be necessary and efficient to test all constituents separately. However, it is of upmost importance that uncertainties associated with various approaches used for the assessment of such substances, including the weight of evidence approach, are understood by regulators to ensure that appropriate regulatory actions can be taken. Discussions are ongoing between authorities and other stakeholders to find strategies / approaches to overcome the challenges to determine the hazards and risks of UVCBs and to reflect on how to best use the data generated to serve more than one regulatory processes (Harmonised classification and labelling, PBT assessment, risk assessment). For instance generating toxicity data that would be of use for PNEC derivation, classification and the T assessment under PBT assessment. Whether this is possible is still under discussion and will be reflected together with the use of specific testing methods such as testing the water accommodated fraction (WAF).

54
Difficulties in regulating UVCBs: Industry perspective
D. Lyon, Shell Oil Company / Shell Health Risk Science Team; G. Whale, Shell Health / Risk Science Team
Chemical risk assessment is based on the hazard and exposure of the substance. The approaches for these assessments is derived predominantly from methods for single substances such as crop protection chemicals, that have the potential for long range transport, bioaccumulation and biomagnification. However, significant challenges are encountered when these same approaches are applied to substances that do not fit this profile, such as with substances of unknown or variable composition, complex reaction products and biological materials (UVCBs).

Challenges arise in the test design, the interpretation of hazard data, the determination of the fate of the material and the quantification of exposure. Although the Organization for Economic Cooperation and Development (OECD) offers guidance on how to adapt existing test methods for difficult substances, there is limited guidance on how to conduct risk assessments for UVCBs. Industry experience has shown that the nature of UVCBs defies a single approach for risk assessment, necessitating tailored hazard and fate assessments with variable regulatory acceptance. One approach is to assess the persistence (P), bioaccumulation potential (B) and toxicity (T), referred to as PBT assessment, of UVCB constituents. This approach relies on Weight of Evidence (WoE) to provide both a clear understanding of the composition of the substance and to identify when constituents meet PBT criteria. WoE is especially critical given that existing methodology for hazard assessment of UVCBs is poorly defined. Additionally, care should be taken regarding using precautionary principles to identify PBTs and consequently designate UVCB substances as a Substance of Very High Concern (SVHC) because these assessments do not account for exposure. Since >20% of the substances on existing chemical inventories are UVCBs, there is a significant need to improve the current approaches for hazard and risk assessment of UVCBs. This presentation gives a brief overview of UVCB hazard assessment approaches that are fit-for-purpose and pragmatic. These include adapting existing methodology for P, B, and T testing, grouping substances into categories, and *in silico* approaches. The issues encountered with each of these approaches will be discussed, along with an overview of proposals for improvements being developed based on recent scientific research supported by industry.

55

Petroleum substances: ongoing program to address hazard assessment including how to capture variability in composition

L. Camenzuli, ExxonMobil Biomedical Sciences

CONCAWE addresses variability in hazard assessment of UVBCs in part through development of a comprehensive library of representative constituents. These structures are expected to capture the variability of different potential isomers across substances. QSARs are used to estimate P, B, and T properties for the constituents within a block. Where available, empirical data are used to support this assessment in a tiered approach. Persistence is evaluated using primary half life data from freshwater and seawater, which are then extrapolated to soil and sediment. This database include more than 1200 individual entries across more than 10 major hydrocarbon classes. Bioaccumulation is evaluated using fish BCF data (from aquatic and dietary exposures) and BMF/TMF data in weight of evidence to evaluate secondary poisoning concerns. Blocks that are potentially indicated as P and B are then evaluated for T using empirical data and QSAR. This evaluation is updated on a regular basis as new science and data are developed. Future work plans will also be discussed.

56

The Environmental Assessment of Natural Complex Substances under REACH

K. Jenner, Givaudan / Global Regulatory Affairs & Product Safety; E. Angelini, Mane; C. Arregui, IFRA; C. Bringer-Guerin, CIHEF; M. Diop, Mane; S. Gimeno, Firmenich / Legal and Compliance; D.T. Salvito, Research Institute for Fragrance Materials (RIFM) / Dept of Environmental Science; T. Wolf, IBACON GmbH / Worldwide Regulatory Affairs for Chemistry

Natural Complex Substances (NCS) of botanical origin are a very diverse family of substances that are notably used as ingredients in fragrance formulations, which are incorporated into personal care and household consumer products. Because of their biological nature, several factors such as the region of growth, the climate within the region, the part of the plant used as source material and the process applied lead to natural variations in their chemical composition. Their complexity varies widely from simple substances with only a few constituents to very complex substances comprising more than 100 constituents which cannot be fully characterised. Further, constituents of an NCS may exhibit different physico-chemical, fate and effect properties that are relevant for their environmental assessment. The European Federation of Essential Oils (EFEO) and the International Fragrance Association (IFRA) have published guidance to help companies, many of whom are small and medium sized enterprises, fulfil their legal requirements for the environmental assessment of natural complex substances under REACH (https://echa.europa.eu/-/guidance-on-environmental-assessment-for-essential-oils-now-available). The guidance, prepared by environmental experts from the fragrance and essential oil industries in close cooperation with the European Chemical Agency (ECHA) was specifically aimed to support the 2018 REACH deadline, under which the vast majority of these substances fell (tonnage band below 10t). The ECHA Substance Identification Guidance generally considers that NCS fit the sub-category of "UVCB sub-type 3". However, they may also be considered as mono- or multi-constituent substances based on their composition and level of characterisation. The nature of the NCS will affect the approach chosen for environmental assessment. Factors such as knowledge of constituents, difference in properties amongst them, technical limitations in testing and feasibility to generate new data will influence the strategy for any given NCS. The guidance document considers assessment based on specific constituents, on the basis of blocks of constituents and on the basis of information on the NCS itself. It provides illustrations and examples of how they might be applied for the purposes of environmental classification and labelling, PBT assessment and environmental risk assessment. Specific considerations and issues related to NCS are also discussed. In this presentation case-studies taken from the guidance will be used to demonstrate the challenges in performing environmental assessments of natural complex substances.

Micro(Nano)plastic Pollution: Tackling the Plastic Problem by Identifying Sources, Investigating Fate and Novel Approaches (II)

57

Degradation and toxicity of microplastic fibres and their role as a source of emerging pollutants

A. Booth, SINTEF Ocean / Environmental Technology; L. Sørensen, SINTEF Ocean / Environment and New Resources; D.T. Rogstad, Norwegian University of Science and Technology / Biology; S. Sait, Norwegian University of Science and Technology / Chemistry; D. Altin, BioTrix; M. Wagner, Norwegian University of Science and Technology NTNU / Bioanalytical Toxicology Group; A. Asimakopoulos, Norwegian University of Science and Technology / Chemistry; I. Salaberria, NTNU University / Biology

Microplastic fibres (MPFs) are increasingly being reported as one of the dominant forms of microplastic pollution in aquatic environments. Clothing and textiles produced from synthetic fibres such as polyester (PES), polyacrylic (PAC) and nylon (PA) are considered some of the main sources of MPFs. However, there has been little focus on the environmental fate and effects of MPFs compared to microplastic particles and fragments. In the current study, the environmental fate of MPFs was studied by long-term UV degradation studies using a suite of 5 MPFs with different physical and chemical characteristics (PES, PAC and PA) under freshwater and marine conditions. A detailed chemical characterisation of the pristine test materials was conducted, using GC-MS, LC-MS and ICP-MS to identify the type of additive chemicals present. Degradation studies were conducted in sterile synthetic freshwater (algal culture medium, TG201) and sterile-filtered seawater. Exposures were conducted in 35 mL quartz glass tubes using an Atlas Suntest CPS+ with Xenon lamp generating 65 W/m^2 light intensity and fitted with a daylight filter (300-400 nm). The endpoints studied after 5 and 10 months were changes in MPF size (light microscopy and SEM), polymer chemistry and surface properties (ATR-FTIR), and the leaching and degradation of additives (colorants, UV-stabilizers, softeners). The release of additive chemicals and their possible photodegradation to intermediate products was investigated as part of the UV degradation studies. In addition, we investigate the potential for the same suite of MPFs and their leachates to elicit toxicological responses in a marine microalga. Effects on algal production, photosynthetic activity and lipid content were assessed as a function of polymer type, fibre length, concentration, as well as the additive chemical profiles of the different MPF leachates.

58

Transgenerational effects of secondary microplastics and natural particles on Daphnia magna

C. Schuer, T. Thalau, S. Zipp, Goethe University Frankfurt / Dpt. Aquatic Ecotoxicology; M. Wagner, Norwegian University of Science and Technology NTNU / Bioanalytical Toxicology Group

Most standardized ecotoxicological tests, such as the "*Daphnia magna* reproduction test" (OECD Guideline 211), cover up to one generational cycle, only. Additionally, they are not adapted to analyze the impacts of suspended particles. A number of publications so far have shown a decrease of feeding activity in Daphnia in the presence of suspended materials which may lead to adverse effects. While standard toxicity testing optimizes among other parameters food supply to ensure health and high reproductive output, these conditions are not representative of the natural environment. This is especially true if the agent under investigation is a suspended solid that is suspected to at least partially act via reducing the energy uptake. Thus, artificially high food availability during exposure plus initially high maternal energy reserves would buffer effects modulated through energy uptake during a short time frame. Accordingly, we exposed four consecutive generations of *D. magna* to three concentrations (400, 2000 and 10000 particles mL^{-1}) each of irregular polystyrene microplastics and kaolin as natural reference particle. The individuals in the treatment groups were fed a reduced amount of algae (0.05 mg carbon $individual^{-1}$ day^{-1}) while we also included a regularly fed control group (0.2 mg carbon $individual^{-1}$ day^{-1}; according to OECD 211). In the exposure to the highest microplastic concentration, we observed an extinction of the first generation daphnids within 21 d. The reproduction, growth and survival of daphnids exposed to 2000 particles mL^{-1} declined over two generations and completely collapsed in the third generation. Interestingly, exposure to a similar concentration of kaolin did not affect *D. magna* over the course of the experiment. As expected, reduced food supply resulted in a decline in reproductive output after the first generation in all treatments. Kaolin treatments showed reproduction that was higher than both the low-food control and the PS treatments. Overall, the PS particles combined with food limitation negatively affect exposed populations to the point of extinction while kaolin did not have such effect.

Potential impact of micro- and nanoplastic particles on metal speciation and bioavailability in aquatic media

R.M. Town, Systemic Physiological and Ecotoxicological Research (SPHERE), University of Antwerp / Department of Biology (SPHERE Research Group); H.P. van Leeuwen, Wageningen University and Research / Physical Chemistry and Soft Matter; R. Blust, University of Antwerp / Department of Biology (SPHERE Research Group)

Plastic particles collected from aquatic systems are typically found to carry a range of associated metal species, some of which are potentially toxic to biota, e.g. Cd^{2+} and Pb^{2+}. The metal content of microplastics (MPs) and nanoplastics (NPs) arises from a combination of the inherent components of the original polymer formulation (stabilizers, pigments, etc.) as well as the sorption of metal species from the environment onto and into the polymer matrix. Metal species may also be associated with organic matter that is sorbed on the surface of the particles. It follows that the amount of metals associated with MPs and NPs will evolve as a function of their residence time in the water column, with consequences for the chemical speciation, bioavailability and potential toxicity of trace metals in aquatic ecosystems. As a first step to gaining mechanistic insights into the involved processes, we present an elementary model, based on spherical geometry, to describe the association and release kinetics of metal species from MPs and NPs. The focus is on release kinetics of metal ions from MPs and NPs that have been immersed/suspended in an aquatic system for an extended period, in the context of their ingestion by biota. Within the body of the plastic particle, metals may be present as e.g. free (partially hydrated) ions and inner-sphere complexes with the polymer backbone and/or various additives. The overall release kinetics of metal species from the plastic particles is governed by the relative magnitude of the rate of diffusion within the particle body as compared to the rate of dissociation of inner-sphere complexes. The effective diffusion coefficients for metal species within plastic polymers are many orders of magnitude lower than those applicable for hydrated metal ions in bulk aqueous media. Thus, for not too strong inner-sphere complexes, the rate of diffusion of metal ions within the particle body will largely govern the overall release kinetics. We analyse practical examples in this context. The outcomes highlight the significance of particle size and residence time within biota for predictions of the potential bioavailability of metal species associated with MPs and NPs.

How ingestion kinetics influence microplastic bioaccumulation and toxicity in Antarctic krill (Euphausia superba)

A. Dawson, Australian Institute of Marine Science; W. Huston, University of Technology Sydney / School of Life Sciences; S. Kawaguchi, Australian Antarctic Division / Australian Government Department of the Environment and Energy; C.K. King, Australian Antarctic Division; R. Cropp, Griffith University / Griffith School of Environment; S. Wild, P. Eisenmann, Griffith University; K. Townsend, University of Queensland; S. Bengston Nash, Griffith University

The discarding of plastic products has led to the ubiquitous occurrence of microplastic particles in the marine environment. The uptake and depuration kinetics of ingested microplastics for many marine species still remain unknown despite the importance for understanding bioaccumulation potential to higher trophic level consumers. In this study, Antarctic krill (*Euphausia superba*) were exposed to polyethylene microplastics in order to quantify acute toxicity and ingestion kinetics, providing insight into the bioaccumulation potential of microplastics at the first-order consumer level. In the 10 day acute toxicity assay, no mortality or dose dependant weight loss occurred in exposed krill, at any of the exposure concentrations (0, 10, 20, 40, or 80 % plastic diet). Krill exposed to a 20% plastic diet for 24 hours displayed fast uptake (22 ng mg^{-1} h^{-1}) and depuration (0.22 h^{-1})rates, but plastic uptake did not reach steady state. Efficient elimination also resulted in no bioaccumulation over an extended 25 day assay, with most individuals completely eliminating their microplastic burden in less than 5 days post exposure. Our results support recent findings of limited acute toxicity of ingested microplastics at this consumer level, and suggest sublethal chronic endpoints should be the focus of further ecotoxicological investigation.

61

Translocation of 14C-nanoplastics in the scallop Pecten maximus at environmentally realistic concentrations

M. AL SID CHEIKH, University of Plymouth / Marine sciences and engineering; S.J. Rowland, University of Plymouth / School of Geography Earth and Environmental; K. Stevenson, Charles River; C. Roleau, Peches et Oceans Canada; T. Henry, Heriot-Watt University / The School of Energy, Geoscience, Infrastructure and Society; R.C. Thompson, Plymouth University / School of Marine Science and Engineering

Studies that investigated the uptake and effects of nanoplastics in marine organisms have been conducted at what may be unrealistically high concentrations. This is due to the analytical challenge that represents tracking plastic particles in biological matrices at environmentally relevant concentrations. Here, we present the results of pulse exposures of ^{14}C-radiolabeled nanopolystyrene to the bivalve *Pecten maximus*, at what have been predicted to be environmentally relevant concentrations (< 15 μg L^{-1}). Our results show that the uptake was rapid and greater for 20 nm than for 250 nm particles. Autoradiography of bivalves sampled after the 6 h exposures showed accumulation of 250 nm nanoplastics in the intestine, while 20 nm particles were dispersed throughout the whole-body, possibly indicating translocation across epithelial membranes. Yet, depuration was also relatively fast for both sizes; 20 nm particles were no longer detectable after 14 d, although some 250 nm particles were still detectable after 48 d. As such, the particle size apparently influences the biokinetics and recommends further work on chronic exposures. Modelling extrapolations suggested that it could take up to 300 d of continued environmental exposure to reach a steady state although the concentrations would still be below 2.7 mg g^{-1}. Comparisons with previous works in which bivalves were exposed to non-plastic (silver) nanomaterials of similar size (20 nm), suggest that nanoparticle composition may also influence its biokinetics.

Effect Modelling for Regulatory Risk Assessment: Current Applications and Future Directions (II)

63

Simplifying DEBkiss to model sublethal effects of chemicals

N. Sherborne, Syngenta / Environmental Safety; N. Galic, Syngenta Crop Protection Inc. / Environmental Safety

The recent scientific opinion published by EFSA has cleared the General Unified Threshold model of Survival (GUTS) for use in ecological risk assessment (ERA)) for aquatic invertebrates, fish, and aquatic stages of amphibians. However, in chronic toxicity studies the most sensitive endpoint is often a sublethal effect on an organism's size or its fecundity. We present a modelling approach based on DEBkiss and inspired by the procedure used by GUTS models. The simplicity of the model means that non-experts should be comfortable using and understanding the the model and interpretting its results. Using simplified DEB theory means that models can be calibrated based on standard laboratory study data alone. We demonstrate the suitability of the model using a chronic toxicity study of a hypothetical herbicide as a case study. This simplified and self-contained method could form the basis of a user friendly tool for sublethal effect modelling and prediction, following the path of projects to produce user friendly GUTS tools.

64

The combined potential of species-traits and mechanistic effect models

S. van den Berg, Namur University; A. Focks, Wageningen Environmental Research / Environmental Risk Assessment Team; P. van den Brink, Wageningen Environmental Research

A key challenge in ecological risk assessment (ERA) is to assess the potential risk of chemicals to the wide range of species in the environment on the basis of laboratory toxicity data derived from a limited number of species. Recently, it has been proposed that the inclusion of species traits in ERA could provide a useful description of species assemblages in nature and has the potential to replace classical taxonomic approaches. Additionally, there is a growing recognition that the use of mechanistic approaches in ERA, especially quantitative models, may improve predictive and extrapolative power. An example of such quantitative mechanistic effect models are toxicokinetic (TK)- toxicodynamic (TD) models of the General unified Threshold models of Survival (GUTS) framework, which link external exposure and survival effects by describing dynamically the process of TK (uptake, biotransformation, and elimination) and TD (damage/hazard, internal recovery and thresholds). We hypothesise an amplified combined potential of GUTS models and trait-based approaches, due to the mechanistic match between species traits and GUTS parameters. We test this by performing linear regressions between i) classical sensitivity endpoints (LC50 and EC50) and species traits, and between ii) GUTS parameters and species traits. Additionally, we implemented a cross-validation step that uses predicted GUTS parameters as an input for the prediction of sensitivity endpoints. The whole analysis is done for twelve freshwater arthropods exposed to chlorpyrifos. We find that neither of the standard sensitivity values, i.e. the LC50 or EC50, showed a strong correlation with traits (option i), whilst multiple quantitative links between traits and/or trait combinations and process based GUTS model parameters could be established (option ii). Our results demonstrate the combined potential of mechanistic effect models and trait-based approaches. However, results from the cross-validation and the final prediction of sensitivity endpoints from GUTS parameters show that methods still can be improved further, e.g. by the further division into functional groups or extension of trait collections. Additionally, the model should be validated more extensively by adding other species.

65
Recovery assessment in stochastic population modelling
M. Kattwinkel, S. Kunz, University of Koblenz-Landau / Quantitative Landscape Ecology; O. Jakoby, Rifcon GmbH / Regulatory Sciences - Population Modelling and Statistics
Environmental risk assessment of pesticides allows some population level effects to non-target species under certain conditions (recovery option; EFSA 2016) when it can be shown that the population under investigation recovers within an acceptable period of time. Population modelling is a valuable tool in addition to field and semi-field studies to assess recovery. However, so far there is no explicit guideline available how to estimate recovery times from simulated population dynamics, and the methods applied in the scientific literature differ greatly. In particular for stochastic population models (e.g. individual-based models, IBMs) with virtually unlimited numbers of replicates there might always be a statistically significant difference between sets of control and treatment populations. For a sound and reproducible evaluation of simulation model results with regard to population recovery it is important to understand the consequences of several choices: (1) the accepted difference between control and treatment to consider populations as recovered; (2) the method used to estimate this difference; (3) the consideration of stochastic processes resulting in short-term divergence. In this study, we investigate how robust and conservative different methods for the estimation of population recovery times are using an IBM that simulates population dynamics after the application of a hypothetical pesticide. We introduce different methods based on hypothesis testing, percentiles and quotients, and discuss their specific characteristics when assessing recovery. Additionally, we investigate the role of thresholds (maximum allowed difference between control and treatment) and other control parameters (e.g. percentiles used to aggregate over replicates and minimum time period to ensure persistent recovery). We also discuss the impact of the models variability as well as seasonal fluctuations in the population dynamics. Finally, we give recommendations on what methods lead to ecologically meaningful and robust results.

66
Evaluation of a population model for ecotoxicological risk assessment
E. McVey, J. Wassenberg, Ctgb; A. Barsi, Ctgb / Dept of Theoretical Biology; D. Kulkarni, Ctgb; A. Focks, Wageningen Environmental Research / Environmental Risk Assessment Team
In contrast to the individual protection foreseen for humans, under the auspices of the regulatory risk assessments for ecotoxicology, protection of populations is assumed to be of greater relevance than protection of individuals. This adds an extra layer of complexity to the risk assessment, as determination of what effects, and what level of those effects, would result in a population level effect remains a large unknown. As a conservative measure, it is assumed that any effects which would result in massive acute toxicity or effects on reproduction would result in population level effects. Furthermore, conservative assumptions are made for the exposure of the entire population (it is assumed that the entire population will be exposed at the same, high, level. However, while it is assumed that this is a conservative path, it is unlikely to be realistic for most uses being assessed. For that reason, population modelling has been developed in order to try to address a more relevant exposure for a population and determine a more likely population level effect. This presentation will summarize our experiences in evaluating a population model for small mammals and conclude with our vision of the pros and cons of this model as a stand-alone and in the context of the regulatory risk assessment for birds and mammals from pesticides in the EU

67
Critical Evaluation of Population Models for the Environmental Risk Assessment of Plant Protection Products
J.M. Becker, Helmholtz Centre for Environmental Research / System Ecotoxicology; T. Jager, DEBtox Research / Dept of Theoretical Biology; S. Kramer-Schadt, Leibniz Institute for Zoo and Wildlife Research / Department of Ecological Dynamics; M. Franz, Leibniz Institute for Zoo and Wildlife Research / Deptartment of Ecological Dynamics; M. Solé, UBA - Federal Environment Agency; S. Duquesne, German Environment Agency; S. Pieper, German Federal Environment Agency UBA / Plant Protection Products; M. Liess, Helmholtz Centre for Environmental Research GmbH - UFZ / System-Ecotoxicology
Individual-based mechanistic effect models are increasingly proposed in higher tier studies for the environmental risk assessment (ERA) of plant protection products (PPP). The models have been often applied to demonstrate that effects in lower tier studies will not translate into unacceptable effects on populations under more realistic conditions. We evaluated seven population models and case studies of their application in ERA from a scientific point of view. The models address the aquatic species *Daphnia magna* (IDamP, Preuss et al. 2009), *Chaoborus crystallinus* (Strauss et al. 2016), *Asellus aquaticus* (MASTEP, Van den Brink et al. 2007), the springtail *Folsomia candida* (SpringSim, Meli et al. 2013) and the small mammals *Apodemus sylvaticus* (Liu et al. 2013), *Microtus agrestis* (ALMaSS, Topping et al. 2012) and *Microtus arvalis* (eVole, Wang 2013). Model mechanisms were scientifically justified. The models address standard focal species in ERA, which are typically less ecologically vulnerable due to short generation time and high reproduction that provide high potential for recovery. The case studies did not consider to which extent the results might cover for additional species, which is not according to the claim of higher-tier studies. A considerable source of uncertainty regarding model predictions was identified because population models represent isolated populations without community context, strictly limiting their applicability in ERA. The models typically predicted fast recovery due to density-regulation and recolonisation, which can be undermined by predation and interspecific competition. Simulating ecological processes that reduce the risk of PPP (recolonisation) without also simulating processes that increase the risk (biotic stressors) may not increase realism but result in unbalanced ERA. An extension to community models would be the next logical step. While the population dynamics without PPP exposure have been validated for most models, more effort should be devoted to test the predictions of PPP effects. The case studies applied models in ERA without assessing to which extent relevant predicted endpoints (extinction risk, recovery time) match real-world data. Environmental properties (landscape composition, farming practices) can significantly affect the model output. We conclude it is crucial to establish specific environmental scenarios and protection goals for higher-tier modeling that can be addressed by modelers and risk assessors.

Latest Developments and Future Needs for Higher-Tier Studies, Risk Assessment and Risk Management in the Regulation of Biocides, Pesticides and Pharmaceuticals (II)

69
Latest developments of guidance and guidance-related documents on exposure assessment for biocides and introduction to the risk assessment tool EUSES 2.2.0
H. Schimmelpfennig, ECHA-European Chemicals Agency / D1 - Biocides; E. Nogueiro, European Chemical Agency ECHA / D1
The aim of the talk is to (1) provide an overview on the latest development of guidance and guidance-related documents and to (2) introduce the new EUSES version 2.2.0. (1) Guidance and guidance-related documents related to exposure assessment like the emission scenarios or emission scenario documents (ESD) are continuously being developed by different parties involved in the biocide assessment (i.e. member state, ECHA or industry). During 2017 and 2018 the focus was on the following items: Revised BPR guidance Volume IV Environment (Part B+C) v2.0 - changes in exposure assessment ($PEC_{initial}$ versus PEC_{TWA}); Revised Emission Scenario Document for PT 6 - In-can preservatives; Revised Emission Scenario Document for PT 14 - Rodenticides; Revised scenarios for PT 18 (Insecticides); WG recommendation on the assessment of precursors of in situ generated active substances; Guidance on aggregated exposure assessment; Single emission scenarios for several product types (PT 3, PT 18, PT 2, PT 4, PT6); Development of core emission scenarios. (2) EUSES is a decision-support instrument for the quantitative assessment of exposure and risks of biocides (and other chemical substances). It is based on the EU Technical Guidance Documents (TGD) (→ Vol. IV Part B for Biocides/REACH R16). Since 2014, JRC is no longer involved in EUSES related legal frameworks and developments/revisions after 2012 were no longer implemented (→ 6 ESDs + several single emission scenarios). EUSES update was initiated by ECHA in 2017 resulting in EUSES version 2.2.0, published in Q1 2019. The focus of the update was on biocides only. The IT technology and User interface remained unchanged. Missing emission scenarios were added in the release module, the release module as such was revised for the already existing emission scenario in EUSES. In addition, direct release was implemented in the Fate and distribution module as well as in the Risk characterisation module. The new SimpleTreat version 4.0 was implemented.

70
Could a spatially distributed modelling approach enhance post approval considerations for veterinary medicines?
C. McMillan, G. Hughes, J. Carnall, Cambridge Environmental Assessments
The environmental risk assessment framework adopted in Europe for assessing the surface and groundwater risk from veterinary medicines used to treat livestock follows a tiered approach. The initial exposure assessment is a simplistic approach, with the FOCUS suite of models (FOrum for Co-ordination of pesticide fate models and their USe) often subsequently required for higher tier surface and groundwater refinement. Standard FOCUS scenarios defined within the guidance are intended to represent realistic worst case scenarios for assessing leaching behaviour and surface water risk. However, this approach does not help inform post approval considerations such as identifying the regions most vulnerable to groundwater contamination or surface water risk. In this presentation we consider how this could be achieved for groundwater assessments by conducting a scoping

assessment using the current Okehampton scenario and comparing it to a spatially distributed version of the metaPEARL model (Tiktak et al., 2006). This implementation of the metaPEARL model was underpinned by an environmental database at 1 km resolution describing (i) land cover using the CORINE 2012 dataset (ii) soils data sourced from the EU Soil Data Centre e.g. EFSA spatial dataset v1.1 (Heiderer, 2012) and OCTOP (Jones et al., 2004) and (iii) climate data from WORLDCLIM (Hijmans et al., 2005). In some cases soil properties were modified to represent permanent grassland soils. The spatially distributed PECgw values produced were analysed at a range of spatial scales including NUTS2, Member State, pesticide registration zones defined by directive 1107/2009/EC and climatic zones. The results indicate that the current approach used in the registration process for veterinary medicines masks a wide variation in the risk as predicted by a more detailed, spatially distributed approach. This presentation illustrates how a more spatial approach to the environmental risk assessment of veterinary medicines could help provide clarity on the environmental risk posed by authorised products in regions within Europe, particularly in situations where environmental risks are identified but the veterinary medicine product is approved due to other considerations (e.g. animal welfare). This type of approach could help inform decisions on risk management and facilitate a more targeted approach to ecopharmacovigilance and drinking water protection.

71

Addressing the knowledge gap in relation to ecotoxicological impacts of biocidal active substances and environmentally relevant metabolites

M. BLAZQUEZ, INKOA SISTEMAS / RTD; I. Ranero, INKOA SISTEMAS; O. Andreu-Sánchez, Xenobiotics; D. Hernandez-Moreno, INIA / Environment; M. Fernandez-Cruz, INIA - National Institute for Agricultural and Food Research and Technology / Environment

The approval of biocidal active substances (BAS) in agreement with the Biocidal Products Regulation (BPR) requires, as a part of the core data set, single species toxicity data on a number of selected organisms assumed as representative of the natural ecosystems. Such information is also needed for the ecotoxicologically relevant metabolites, which are defined by the ECHA as any minor or major metabolite which poses a comparable or higher hazard than the active substance^[1]. Within the LIFE COMBASE Project, chemoinformatic approaches are being developed for the assessment of the ecotoxicological impacts of BAS and their corresponding environmentally relevant degradation products. With the aim of generating new data to validate developed *in silico* models, four different *in vivo* ecotoxicological studies to aquatic organisms have been carried out including: acute toxicity testing on fish, short-term toxicity testing on *Daphnia magna*, growth inhibition study on algae and inhibition of microbial activity. Fish acute toxicity test has been carried out using *Oncorhynchus mykiss* (rainbow trout) as target species, following the OECD TG 203 whereas assays on *Daphnia*, algae and microorganisms have been carried out in agreement with the OECD TG 202, OECD TG 201 and OECD TG 209 tests, respectively. The present work includes data obtained on three BAS: 2-phenoxyethanol (currently in approval process for Product Types –PTs- 1; 2; & 4 and not authorized for PT13), chloramin B (currently in approval process for PTs 2; 3; 4 & 5) and sodium pyrithione (currently in approval process for PTs 2; 6; 7; 9; 10 & 13 and not authorized for PT3), and also data corresponding to five metabolites: 3-phenoxybenzyl alcohol (metabolite from D-Phenothrin); benzimidazole (from thiabendazole); cyanoacetamide (from DBNPA); benzenesulfonamide (from chloramine B) and cis-2,6-dimethylmorpholine (from fenpropimorph). In general, results obtained are coherent for the different trophic levels considered, although in some cases fish and microorganisms are the most and least sensitive species, respectively. The results obtained allow stablishing a PNEC for these substances which can be used for risk assessment and management purposes. **Acknowledgements:** LIFE-COMBASE project (LIFE15 ENV/ES/000416) <br clear="all" /> [1] REF: Guidance on information requirements – GUIDANCE ON REGULATION (EU) Nº 528/2012 COVERING THE MAKING AVAILABLE ON THE MARKET AND USE OF BIOCIDAL PRODUCTS (BPR) Version 1.0. 72

Risk Mitigation Measures for Pesticides in the EU (MAgPIE project) - challenges and recommendations from the workshop experts

A. Alix, Corteva Agrisciences / Risk Management

The MagPIE project initiated in 2012 allowed the development of a toolbox to mitigate environmental risks posed by plant protection products used in agriculture. The proceedings were published in 2017, which propose an inventory of the risk mitigation measures in place in European Member States as well as recommendations to facilitate further development and implementation. These proceedings reflect the view of 95 experts from 24 European countries, together with experts from Switzerland, Norway, the United States of America, the European Commission and the European Food Safety Authority, and representing regulatory agencies in charge of the risk assessment of plant protection products, regulatory authorities in charge of the risk management and decision making, crop protection industry, universities and research institutes, technical institutes involved in the development of risk mitigation tools, or the measurement of their performances, farmers and agriculture advisors, and Non Governmental Organisations. The project allowed to identify the most promising tools for the mitigation of pesticide transfers and possible environmental risks, which gathered risk mitigation measures and tools already impleneted in European countries but also the most promising tools for a short term implementation. The proceedings also discuss the challenges met along the stakeholder chain when implementing, by farmers, regulators, risk assessors, or decision makers. This poster aims at listing these challenges were identified during the MAgPIE workshop together with the recommendations of the expert group to tackle them, including illustrated examples.

73

From national to regional risk mitigation measures - opening the toolbox for conditions of use for plant production products

G. Czub, Federal Office of Consumer Protection and Food Safety BVL / Plant Protection Products; C. Kula, Fed. Office for Consumer Protection & Food Safety / Department of Plant Protection Products

In the EU Member States, an authorisation of plant protection products (PPP) is only granted if the risk assessment demonstrates that by application of appropriate mitigation measures the risk for the environment remains acceptable in any of the landscapes in which the product might be used. In general, an authorisation is granted on a national scale in conjunction with risk mitigation measures to be applied independent on the regional conditions. For several reasons it might be worse to consider a revision of this approach: (i) active substances might exhibit characteristics critical only under certain circumstances but otherwise effective and preferable means for the plant protection and agricultural production, (ii) certain regional structures might require specific protection or have characteristics impeding the application of common national mitigation measures, (iii) the number of active substances available in authorised PPP decreases remarkable, hampering an effective pest control and resistance risk management. Regions in focus for specific mitigation measures include, among others, drinking water abstraction areas, sites of high biodiversity value, but also highly trenched areas of small field sizes. For a sustainable plant protection a paradigm shift might be required, allowing for an authorisation (or rejection) of PPP for use in specific regional areas instead of an authorisation on an entire national scale. Challenges of such an approach are, among others, technical prerequisites such as detailed regional data compilations (e.g. GIS-mapping), its consideration in the regulatory risk assessment, the communication of measures and restrictions to the end user and the possibility to control these specific mitigation instruments. Monitoring programmes might become an essential prerequisite in order to evaluate the applicability and effectiveness of regional mitigation measures. Taking into account the current developments and the associated consequences for plant protection, a shift from nationally applied restrictions of use and mitigation measures to restrictions and mitigation measures on a regional scale might be required to maintain a high environmental protection level.

74

New Approaches to Environmental Risk Assessment of Veterinary Pharmaceuticals at US Food and Drug Administration's Center for Veterinary Medicine

H. Zahner, E.M. Silberhorn, U.S. Food and Drug Administration / Center for Veterinary Medicine

This presentation will discuss current regulations, guidance, policy, and approaches used at the US Food and Drug Administration's (FDA's) Center for Veterinary Medicine (CVM) to prospectively evaluate the potential for environmental impacts of new animal drugs. Under the National Environmental Policy Act (NEPA), FDA is responsible for determining whether the agency's actions (e.g., approval of a new drug) will result in potential environmental impacts. NEPA provides tools, such as environmental assessments (EA) and categorical exclusions from the requirement to prepare an EA, for evaluating the environmental safety of agency actions. In addition, CVM has published a Guidance for Industry (GFI) with recommendations on how to conduct an EA that was developed and harmonized with regulatory agencies in the European Union and Japan, and has since been adopted by others. This guidance recommends a tiered approach to testing that includes an evaluation of the fate, transport, and effects of animal drugs in the environment, and recommends using a traditional risk quotient approach when assessing risk. However, CVM's GFI is not applicable to the evaluation of some new animal drugs. For example, the current GFI does not provide agency recommendations on how to estimate potential environmental concentrations in soil or water, or on how to evaluate an animal drug that has an unusual route of exposure (e.g., dietary), is known to be toxic at very low concentrations (e.g., endocrine active compounds, parasiticides), those that bioaccumulate in organisms, or those that persist in the environment. Examples of novel approaches used by the animal drug industry and CVM to address current issues will be presented. In addition, CVM's current and future scientific perspectives regarding the EAs for animal drugs will be discussed.

Alternative Approaches to Animal Testing for Ecotoxicity Assessments: Exploring New And Novel Approaches (I)

Setting the baseline in in vitro bioassays

B. Escher, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology; F.C. Fischer, Hemholtz Centre for Environmental Research - UFZ / Cell Toxicology; L. Glauch, Helmholtz Center for Environmental Research UFZ / Cell Toxicology; L. Henneberger, Helmholtz centre for environmental research - UFZ / Cell Toxicology; M. Koenig, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; R. Schlichting, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology

Cell-based bioassays have become popular in chemical risk assessment and monitoring of environmental samples. With a suite of simple short-term reporter gene activation assays it is possible to obtain a picture of potential chronic adverse effects and information on the modes of action of chemicals and samples in an adverse outcome pathway framework. Recent advances in high-throughput screening such as the Tox21 initiative and ToxCast have generated a large database of effect concentrations for hundreds of endpoints suitable for various risk assessment applications. Despite the rapid advances in this field, some practical questions remain as well as issues with the interpretation of the effect concentrations derived from concentration-response curves. Robotic pipetting platforms increase throughput and permit decrease in bioassay volumes to as little as a few μL but the trade-off are higher evaporative losses and a reduced applicability domain. We derived a cut-off for volatility, which is actually a cut-off related to the medium-air distribution ratio, that is driven not only by the vapour pressure but also by solubility and the protein- and lipid-water partition constants. Further, many reporter gene assay results are compromised by the so-called cytotoxicity burst, where close to cytotoxicity, various reporter genes are activated in a nonspecific fashion. We have not only improved quantification of cytotoxicity but also experimentally derived baseline toxicity QSARs for eight mammalian cell lines. We concluded that any effect concentration that is higher than the inhibitory concentration for cytotoxicity is likely to be an artefact of the cytotoxicity burst. It is notable that the baseline toxicity QSARs were fairly similarly for all cell lines and mass balance modelling demonstrated that the small differences are related to differences in bioavailability and make up of cells and medium, with virtually constant critical membrane concentration, which are also in the same range as the critical membrane concentrations for narcosis in aquatic species. The developed baseline toxicity QSARs help to design experiments, which should always be run up to baseline toxicity concentrations to assure that no effects are overlooked, and to interpret effect data with respect to the degree of specificity of the effect and for *in-vitro* to *in-vivo* extrapolations. This study is part of the CEFIC ECO36 project.

76

Performance of three-dimensional rainbow trout (Oncorhynchus mykiss) hepatocyte spheroids for evaluating biotransformation of pyrene

M.T. Hultman, Norwegian Institute for Water Research; K. Løken, M. Reid, NIVA Norwegian Institute for Water Research; A. Lillicrap, NIVA / Environmental Toxicology

Hydrophobic organic compounds have the potential to bioaccumulate in tissue and lipid reservoirs of aquatic organisms such as fish, potentially causing both short and long-term biological effects. The assessment of a compound's potential to bioaccumulate in fish involves its physicochemical properties (e.g. Log K_{ow}) and rate of biotransformation, using conventional animal (*in vivo*) test methods (e.g. OECD TG 305). Due to the ethical and economical concerns, development of non-animal computational (*in silico*) bioaccumulation assessment models (e.g. Quantitative Structure Activity Relationships) for aquatic vertebrates (fish) have been proposed. To improve existing computational predictions, various *in vitro* tests (e.g. S9 fractions and primary hepatocytes) have been proposed for their suitability as alternative bioaccumulation models. One recently developed model, is the three dimensional (3D) hepatic spheroids of rainbow trout (*Oncorhynchus mykiss*). The aim of present study was therefore to evaluate the metabolic competence of 3D-spheroid hepatic cultures of rainbow trout when incubated with the model compound pyrene (PYR). The results were compared with previously published intrinsic clearance (CL) results for S9 and primary hepatocyte assays. In addition, two different sampling procedures, estimating the total- (i) and free (ii) concentration of PYR and its primary metabolite OH-PYR were assessed. Extraction of total (bound and free) PYR (i) suggested that the spheroids had depleted 33% of the added PYR within 4 h of exposure, further metabolizing a total of 85% and 91% after 24 and 30h respectively. However, when applying the second (ii) sampling procedure, a substantial amount (36%) of the PYR was, within 2 h of exposure, bound to the glass wall of the exposure vial. The PYR continued to be bound (33% and 2%) to the glass wall for the duration of the exposure (6 and 30h, respectively). Log-linear formation of OH-PYR was obtained throughout the study, displaying the 3D-spheroids metabolic competence. The two sampling procedures yielded differently measured $CL_{in\ vitro,\ spheroid,}$ where PYR depletion in the cell+media was highly similar to previously published studies using cryopreserved hepatocytes. The 3D-spheroids demonstrated high reproducibility, log-linear biotransformation of PYR and formation of OH-PYR, indicating that 3D-spheroids are highly metabolically comptetent for 30 h or more.

Integrated alternative approaches for bioaccumulation and toxicokinetics: from in vitro data to in silico models

A. Sangion, University of Insubria / Department of Theoretical and Applied Sciences (DiSTA); L. Bertato, University of Insubria; I. Casartelli, University of Insubria / Department of Theoretical and Applied Sciences DiSTA; K. Foster, Karen Foster Environmental Research / Adjunct Professor, Trent University, Applications of Modelling & Quantitative Methods (AMOD); J.A. Arnot, ARC Arnot Research & Consulting / Adjunct Professor, Department of Physical & Environmental Science/Department of Pharmacology and Toxicology; J.M. Armitage, AES Armitage Environmental Sciences, Inc / Physical and Environmental Sciences; A. Looky, ARC Arnot Research and Consulting Inc.; L. Toose, Liisa Toose Environmental Research; M. Embry, Health and Environmental Sciences Institute HESI; E. Papa, University of Insubria / Department of Theoretical and Applied Sciences

Under REACH, more data for chemicals have been assembled than ever before. Unfortunately, the quality of data is not always adequate and, in many cases, critical information, mainly related to toxicokinetic (TK) processes (i.e., biotransformation rates) is not available. Testing programs are expensive and require a high number of animal lives per chemical, which is why REACH advocates *in vitro* assays as a means to reduce animal-testing. Integrated Testing Strategies (ITS) comprise both testing and non-testing methods, such as *in vitro* testing and computational methods that aim to reduce animal testing and optimize intelligent use of available information to improve chemical hazard and risk assessment. The CEFIC LRI ECO44 "Integrating Bioaccumulation Assessment Tools for Mammals (iBAT-Mam)" project's primary objective is the integration of multiple data streams of TK data in a coherent framework for the assessment of bioaccumulation in mammals. Here, more than 30 years of *in vitro* and *in vivo* TK data (rodents and human) are assimilated and critically evaluated. Then *in vitro-in vivo* extrapolation (IVIVE) models and Quantitative Structure-Activity Relationships (QSARs) are developed to maximize the information available from *in vitro* and *in vivo* measurements. In addition, Quantitative Activity-Activity Relationships (QAARs) are used to examine interspecies correlations and predict missing information by extrapolating from one species to another. This presentation will describe on-going methods to address data gaps in biotransformation rates at multiple levels of biological organization through the development of validated QSARs following OECD guidance. Preliminary correlation analysis performed between intrinsic hepatic clearance measured *in vitro* in rodents and humans revealed high interspecies correlation $R^2 > 0.70$. QSAR models were generated for different structural groups to predict the hepatic clearance in human and rodents. All models are stable, robust ($R^2 > 0.70$ and $Q^2_{loo} > 0.65$), externally validated and predictive when they are applied to generate different splitting schemes with particular attention to the structural applicability domain (AD). In conclusion, *in vitro* biotransformation rate data can be obtained to systematically address uncertainty. New QSARs and predictive methods for rates and half-lives are in development within this project.

78

Detoxification capacity of zebrafish (Danio rerio) early life stages: Characterization of the glutathione conjugation pathway by targeted proteomics and metabolite analysis

A. Tierbach, Eawag / Department of Environmental Toxicology; K. Groh, Food Packaging Forum Foundation; R. Schönenberger, Eawag / Department of Environmental Toxicology; M.J. Suter, Eawag Swiss Federal Institute of Aquatic Science and Technology / Department of Environmental Toxicology; K. Schirmer, Eawag Swiss Federal Institute of Aquatic Science and Technology / Environmental Toxicology

Zebrafish early life stages offer an important model for the study of disease and chemical risk assessment due to their genetic similarity to humans and the availability of well-established high-throughput techniques for toxicity analysis. However, in order to understand the validity of this model for comprehensive assessment of bioactive compounds, it is important to characterize the biotransformation capacity of zebrafish embryos. Here, we focused on detoxification pathways mediated by glutathione S-transferases (GSTs). This enzyme family plays a major role in phase II biotransformation processes, and GST-catalyzed conjugation reactions are a critical contributor to detoxification and clearance of various intracellular metabolites, but also natural toxins and xenobiotic compounds. First, we developed multiple reaction monitoring (MRM) assays that enable monitoring specific GST isoenzymes and GST classes through a combination of proteotypic peptides and peptides shared within the same class. Our analyses showed that a few representatives of the four GST classes (alpha, mu, pi and rho) are present in zebrafish embryos as early as 4 hours post fertilization (hpf). The majority of GST enzymes, however, only become expressed at 72 hpf, followed by a continuous increase in expression [1]. Next, we studied the biotransformation capacity of the expressed GSTs in zebrafish embryos and early larvae exposed to non-toxic concentrations of the reference substrate 2,4-dinitrochlorobenzene (CDNB). CDNB and its mercapturic acid pathway biotransformation products were measured by LC-MS. In parallel, changes in protein expression of cytosolic GSTs were monitored. Our results demonstrate that early zebrafish life stages are able to perform glutathione conjugation reaction with CDNB and to further process the product within the mercapturic acid pathway. The early expression of a wide range of cytosolic GST classes and the functionality of the mercapturic acid pathway supports the functionality of the zebrafish early life stages as an alternative model in toxicology and chemical hazard assessment. [1] Tierbach A, Groh KJ, Schönenberger R, Schirmer K, Suter MJ-F. 2018. Glutathione S-Transferase Protein Expression in Different Life Stages of Zebrafish (Danio rerio). Toxicological Sciences.162(2): 702–712

Developing in-silico predictions of toxicity

C. Iosif, University of Liverpool; P. Antczakp, University of Liverpool / Computational Biology Facility

Human activities, including manufacturing and pharmaceutical processes, increase the abundance of different toxins. The potential environmental impact of the manufacture and use of pharmaceuticals is still not known, and as the number of compounds in the environment is increasing, not all compounds can be tested. *In–silico* approaches, such as quantitative structure-activity relationships (QSARs) models, can be used to address these issues. This type of models have been used for the prediction of the biological activity, toxicity, and other properties, using the chemical structure of the compounds based on the assumption that the structure of a molecule is responsible for the physical, chemical and biological properties. Zebrafish have been exposed to a variety of toxic compounds, including endocrine disruptors, at different concentrations for up to 96h. A log-logistic model was used to calculate the LC50 and the slope of the dose-response curve of each compound. In addition, the General Unified Threshold (GUTS) model of survival, will also be used in order to validate the LC50 values that are going to be used in the generation of a predicting model. For the generation of the model a list of molecular descriptors was obtained using Dragon 7 software, for over 150 toxic compounds. Descriptors such as ALOGP (degree of hydrophobicity), spectral moments and autocorrelation of topological structure (ATS) descriptors, increase the accuracy of our predictive models. Heart-rate data, for up to 96 hours, will be used to generate a model that can predict the heart-rate of the zebrafish, based again on the structure of the molecule. The quantitative structure-activity (QSAR) models will be integrated into the web application, which can take any compound and will be able to provide the user with the predicted LC50 and the slope values and the expected change in heart-rate. The application will help predicting missing experimental data and prioritize chemicals for toxicity testing, which can save time, effort and reduce the number of experimental animals.

QSARs for thiochemicals - a case study of using alternative information for REACH registrations

M. Nendza, Analytisches Laboratorium; J. Ahlers, Consultant; D. Schwartz, Bruno Bock Thiochemicals

A case study on acute aquatic toxicity of thiochemicals is presented to show the possibilities and limitations of filling data gaps with alternative information in accordance with the requirements of REACH [1]. Experimental studies with fish, daphnia and algae are available for several case study chemicals. It is the objective of this study to extract as much information as possible from the available experiments to estimate required data by QSARs, read-across and trend analyses. Thiochemicals are considered to be toxic with an unspecific reactive mode of action (MOA) causing so-called excess toxicity, i.e. the effects are much higher than estimated from baseline QSARs. Differences in toxicity between the groups of thiochemicals are thought to be due to differences in reactivity of the respective sulfur moiety, i.e. toxicodynamic differences. Within each group the thiochemicals share the same reactivity due to the identical sulfur function, but are different with regard to partitioning between biophases related to increasing aliphatic chain length, i.e. toxicokinetic differences. Due to the toxicodynamic and toxicokinetic differences, QSARs, read-across and trend analyses are limited to thiochemicals within the same group. Scientifically valid QSARs for thiochemicals are not available and the present data base is too small to derive new QSAR models that fulfil the OECD principles for the scientific validity of QSARs. Most of the 36 data gaps for 16 thiochemicals to be registered by 2018 were closed by estimates using trend analyses and read-across for thiochemicals within the same group, e.g., thioglycolates or mercaptopropionates. The testing strategies to fill remaining data gaps recommend tests with algae (6 substances) and daphnia (6 substances). Only for two substances experimental (limit) fish studies are recommended. Thus, a substantial (>60%) reduction of animal experiments is possible. [1] Ahlers J, Nendza M, Schwartz D. 2019. Environmental hazard and risk assessment of thiochemicals. Application of integrated testing and intelligent assessment strategies (ITS) to fulfil the REACH requirements for aquatic toxicity. Chemosphere 214:480-490.

Abiotic depletion potentials (ADPs) for elements revisited

J. Guinee, University of Leiden / Institute of Environmental Sciences CML; L.v. Oers, R. Heijungs, Leiden University / Institute of Environmental Sciences CML

In 1995 the original method for calculating the Abiotic Depletion Potentials (ADPs) was published [1]. The ADP of resource i was defined as the ratio of P_i and the square of R_i for resource divided by the same ratio for a reference resource (Antimony (Sb)); hereby P_i represent the annual production (kg/yr) of resource , and R_i its ultimate (crustal-content based) reserve (kg). In 2002 ADPs were updated based on most recent USGS annual production data. In addition, the ADP was sub-divided into two categories and two sets of ADPs: $ADP_{fossil\ fuels}$ and $ADP_{elements}$. Since then, the $ADP_{elements}$ has not changed despite ongoing annual updates of production data and also a few updates of crustal-content data that constitute the basis of the ultimate reserves. Moreover, it was known that the coverage of elements by ADPs was incomplete. These three shortcomings can affect relative ranking of elementary resources and also normalized indicator results for ADP-based abiotic resource depletion. This was realized during the European Commission Product Environmental Footprint pilot project modeling process in 2018, where it was realized that incomplete ADP normalization was incorrectly dominating single score results. On top of this, dealing with annually changing production may need new calculation procedures for the ADP. The present study describes an effort to update the data (P_i and R_i), but with wider ramifications, including an analysis of the changes over time, the resulting variations and a proposal for a more robust updating procedure.

82

Assessment of resource uses with dynamic stock models: ADP as a marginal approach from Hubbert peak theory

A. Helias, INRA LBE / LBE ELSA; R. Heijungs, Vrije Universiteit Amsterdam / Faculty of Economics and Business Administration

In LCIA, the resource issue is still debated and remains the least consensual area of concern. The currently popular assessment models for resource depletion are based on “heuristic” considerations. This presentation deals with the use of a stock dynamic model to address the resource depletion by marginal approach. Based on empirical data simulating the evolution of the exploitation rate, stock dynamics models have been proposed in the literature. It is thus possible to define a mathematical relationship linking the human intervention (the resource extraction) to the impact (the stock depletion). The partial derivative is then used expressing the marginal change and determining the Characterization factors (CFs). This approach was used on fish stocks, and the similarities of the result with the Abiotic Depletion Potential (ADP) proposed by Guinée and Heijungs in 1995 lead us to look at the parallel we can draw. The fish population dynamics model is based on the very common logistic function. This is also the relation used in the Hubbert peak theory. We use the shape of the model to describe the current depleted resource fraction. This fraction equals to zero for a never exploited resource and tends towards one with the depletion. The use of partial derivative therefore makes it possible to define the CF of the resource depletion on the basis of the Hubbert theory. The difference between ADP and Hubbert-based CFs lies only in the constant part of the equations with a fixed (antimony-based) unit conversion factor for ADP and a resource-specific parameter for Hubbert-based CFs. We show here that the original ADP is a very good estimator for the CF derived as a marginal depletion characterization factor from the Hubbert curve with an high correlation (r=0.99 with p-value

Regionalized Global Life Cycle Impact Assessment of Natural Resource Extraction and Processing

L. Cabernard, ETH Zurich / Environmental Engineering; S. Pfister, S. Hellweg, ETH Zurich / Institute of Environmental Engineering

Over the past decades, the continuous growth in human population and economic welfare has increased the pressure on natural resources and the environment to an extent that is not sustainable. Thus, decoupling the environmental impacts from economic growth has been defined as a policy objective by the United Nations Environment Program. For this purpose, detailed assessments that quantify the impacts of global resource production from a life-cycle perspective are crucial, but are lacking so far. Here, we provide a globally regionalized impact assessment of multiple environmental and socio-economic indicators, such as water stress, land-use related biodiversity loss, health impacts due to particulate matter emissions (PM health impacts), together with climate change impacts, value added, compensation of employment, workforce and risks for employment. Further, we developed a new method to allocate these impacts to the extraction and processing of resources, called resource-related impacts in the following. This allowed us to assess the temporal development of multiple resource-related footprint indicators between 1995–2011 for the entire globe and for single nations. The regionalized assessment showed, that all nations have achieved a decoupling of the environmental impacts of their economic growth, but most nations did not achieve a decoupling from their population growth, meaning that the per capita impacts have increased over the past. Further, we discuss the global trade pattern of resource-related impacts over three stages of the supply chain to identify hotspots of production, consumption, and trade of the environmental impacts of key resource types. Results of this regionalized global impact assessment are important to assess progress towards national and global environmental policy targets, and serve as a basis to establish policy options for a more sustainable production of resources. The method developed in this study can be applied on any industrial sector(s) and region of interest to trace its regionalized impacts over the global supply chain from a production, sector output as well as final demand perspective.

Extending the Geopolitical Supply Risk method: Potential for recycling as a risk mitigation strategy

J. Santillán-Saldivar, Université de Bordeaux / The Life Cycle Group CyVi; A. Cimprich, S. Young, University of Waterloo / School of Environment, Enterprise and Development SEED; G. Sonnemann, University of Bordeaux / The Life Cycle Group CyVi

Criticality indicators are being used to inform management decisions on supply risk and use of critical raw materials needed for emerging technologies. Improving and promoting recycling processes is suggested as one of the strategies to support the transition to a circular economy and address the concerns linked to supply risk. Existing methods to assess supply risk of materials based on geopolitical considerations do not consider the potential effects of recycling. This can be overcome by enhancing the Geopolitical Supply Risk (GeoPolRisk) methodology, which can be integrated into a Life Cycle Impact Assessment (LCIA) characterization model. The aim of this study is to provide a measure for the potential reduction of supply risk that can be achieved with domestic recycling. The GeoPolRisk method measures the supply risk of a commodity based on the supply mix to a country and the global production shares of suppliers. A previously published study was used as a baseline for further assessment of potential supply risk reduction attributable to domestic recycling from the perspective of the European Union (EU-27) including recycling indicators made available by the European Commission. A comparison is made between the previous GeoPolRisk results and the updated values after the inclusion of recycling considerations. Two scenarios were studied: a best case scenario (BCS) that assumes a preference for low-risk suppliers and a worst case scenario (WCS) that results in the selection of high-risk suppliers. Independent simulations were developed for the analyzed materials. With the inclusion of recycling considerations into the GeoPolRisk methodology it is possible to obtain a measure of potential supply risk reduction. A powerful feature of this enhanced methodology is the provision of a range that captures the effect of domestic recycling on the supply risk of materials under different scenarios that depend on the purchase decisions made by buyers of raw materials. A novel tool integrated into a LCIA characterization model is provided to help guide decisions regarding the adoption of recycling technologies and the selection of suppliers for product systems. Further application of the methodology can also provide organizations with indicators to promote recycling practices on a national and regional level in order to support the transition towards a circular economy.

Metal and mineral resources in LCIA - The SUPRIM project

J. Guinee, University of Leiden / Institute of Environmental Sciences CML; L.v. Oers, R. Schulze, Leiden University / Institute of Environmental Sciences CML; R.A. Alvarenga, Ghent University / Department of Green Chemistry and Technology; J. Dewulf, EC JRC - IES / Sustainability Assessment unit; J. Drielsma, Euromines

Over the past two decades, life cycle impact assessment methods have received extensive attention and developed into mature methods mostly reflecting the state of the art in the relevant scientific field. Despite these achievements and harmonization efforts by the UNEP-SETAC Task Force on natural resources, there is still a lack of consensus on how to assess abiotic resource use in life cycle impact assessment (LCIA). This lack of a broadly accepted method, likely attributable to the lack of a common perspective on resource use and a common understanding of the potential problem(s) related to the use of resources, was the starting point of the SUPRIM project. The aim of SUPRIM is to obtain an understanding of different stakeholders' views and concerns regarding potential issues which result from the use of resources. The gained insights will be provided in the form of a structured overview of those different views, which will then be used as a basis for further method development. This is being achieved by 'taking a step back' to a structured discussion about potential problems with resource use, and different motivations behind resource management concepts. The project focuses on impacts which occur directly from the use of abiotic resources - more specifically, abiotic resources such as minerals, metals, and natural materials - e.g. sand or natural stone. As one of its first activities, the SUPRIM consortium developed a framework for a structured discussion of different perspectives on resource use. The framework consists of an overarching perspective, a conceptual level ("Modelling Concept"), and a practical implementation level. The framework was first used as basis for a workshop discussion with external stakeholders. Prior to the workshop, the framework was introduced to the external stakeholders by way of a discussion paper including a number of pre-defined perspectives for discussion. Next, the workshop results were adopted as basis to propose best modelling options matching the perspectives and problems identified and prioritized by the workshop participants. The SUPRIM work is currently still ongoing but expected to be finalized in Spring 2019, and we aim to present first details of preferred methods at the conference.

86

Development of a conceptual framework and its associated indicator to take the dissipation of non-energetic abiotic resources into account within Life Cycle Assessment (LCA)

A. Charpentier Poncelet, Université de Bordeaux; P. Loubet, CyVi-ISM / ISM CyVi; B. Laratte, Université de Bordeaux / ENSAM I2M; G. Sonnemann, University of Bordeaux / The Life Cycle Group CyVi

Recent developments for the Natural Resources Area of Protection (AoP) in Life Cycle Assessment (LCA) have put current methods tackling resource use under review by many (e.g. Drielsma et al., 2016; Klinglmair, Sala, & Brandão, 2014). It has been proposed that the safeguard subject for mineral resources is their capacity to fulfill provisioning functions for humans (materials, energy, food, space, etc.) (perspective 2 from Dewulf et al. (2015)). Therefore the damage on resources should be quantified as the reduction or loss of this capacity caused by human activity. Dissipation has been identified as a relevant approach for this perspective compared to methods based on resources depletion (Zampori & Sala, 2017). It allows a better identification of where resource are lost (dissipated), including within the technosphere, and as a consequence lose their potential value for human use. However, no consistent method has been developed to include dissipation within LCA thus far. In this regard, we propose to build a conceptual framework to include dissipation of metals and minerals within LCA. "Key elements", such as dissipation occurring during extraction, production and use, quality limits (e.g. physicochemical limits, including thermodynamics, after which the resource will be permanently lost as an emission or as a final stock within mine tailings or end of life discharge), resource occupation in the technosphere, recycling rates and quality loss are defined in order to make this approach functional. Approaches to measure or evaluate such key elements, and the way their implementation within Life Cycle Inventories (LCI) or Life Cycle Impact Assessment (LCIA) can be done, are presented. Feasibility of the implementation of these elements within the LCA methodology is evaluated and planned future works based on this initial framework are presented. The developed framework represents the first steps towards evaluating dissipation rather than depletion of mineral resources in an LCA context, with an appropriate inventory and impact method. This will lead to the possibility to distinguish between dissipated minerals and recycled ones, which are kept within circular economy and contribute to resource efficiency, and help to support decision-making based on such criteria.

Target and NonTarget Mass Spectrometry for Human and Environmental Exposure Assessment (II)

87

High resolution mass spectrometry to investigate the fate of pesticides during microalgae-based bioremediation treatment of water

E.L. Garcia, IDAEA-CSIC / Department for Environmental Chemistry; C. Postigo, Institute of Environmental Assessment and Water Research IDAEA CSIC / Environmental Chemistry; R. Avila, Universitat Autonoma de Barcelona (UAB) / Departament dEnginyeria Quimica, Biologica i Ambiental; P. Blanquez, UAB / Enginyeria Química; T. Vicent, UAB; M. López de Alda, Institute of Environmental Assessment and Water Research IDAEA-CSIC / Department of Environmental Chemistry

Pesticides are substances highly used for many purposes worldwide. After their use, they may end up in the aquatic environment, representing a risk to exposed organisms. To reduce their environmental impact, it is necessary to develop technologies capable of removing them before their release into the environment or from pesticide-containing waters. In this context, the objective of this work was to study a bioremediation technology based on microalgae to remove pesticides from water. For this, microalgae-based degradation studies were carried out at lab-scale with three different pesticides: acetamiprid, propanil and bentazone. All experiments were performed in triplicate, and controls were used to quantify adsorption and photodegradation. Pesticide degradation was monitored at time zero, and after 2 and 7 days of treatment using liquid chromatography coupled to heated electrospray-high resolution mass spectrometry (LC-HESI-HRMS) detection using a hybrid quadrupole-Orbitrap (Q-Exactive) analyzer. Mass acquistion was carried out in full scan and data-dependent MS/MS mode. This type of analytical approach also allowed the investigation of the degradation products (TPs) formed during the process. The results obtained showed that propanil and acetamiprid were degraded in the presence of the microalgae. Propanil was fully degradated after 2 days of treatment, whereas complete degradation of acetamiprid required 7 days. On the contrary, no degradation at all was observed for bentazone. As for the formation of TPs during the process, only one TP could be identified so far. This TP was found in acetamiprid containing waters and its accurate mass and assigned molecular structure corresponds tentatively to the hydroxylation of the parent compound. Additional chromatographic peaks present in t=2 days and t=7 days samples are under evaluation. Identification of additional TPs would assist in describing microalgae biodegradation mechanisms. *Acknowledgement* - This work has received funding from the Government of Catalonia (2017 SGR 01404 and 2017 SGR 00014), the Spanish State Research Agency (AEI) and the European Regional Development Fund (ERDF) through the project BECAS (grant number CTM2016-75587-C2-2-R), and the European Union's Horizon 2020 Research and Innovation Programme under grant agreement No. 727450. This presentation only reflects the authors' views and the Commission is not responsible for any use that may be made of the information it contains.

Pharmaceuticals and their Transformation Products in Hospital Wastewater and Conventional Wastewater Treatment Plants

L. Niemi, M. Taggart, K. Boyd, Environmental Research Institute North Highland College University of the Highlands and Islands; Z. Zhang, The James Hutton Institute / Environmental & Biochemical Sciences; S. Gibb, Environmental Research Institute North Highland College University of the Highlands and Islands

Pharmaceuticals (pharma) are extensively used and introduced into our wastewater where inadequate removal leads to release into surface waters. Hospitals have been identified as a major point-source for pharma entering municipal sewers and waterways, and rural hospitals are of concern as subsequent treatment may be carried out with smaller, less advanced wastewater treatment plants (WWTPs). The importance of characterising pharma degradation products is becoming more evident as there is little information available on their presence, behaviour and biological activity. Characterising the effect hospitals have on pharma pollution in municipal wastewater and understanding pharma degradation behaviour and removal in WWTPs are necessary to inform future decision making regarding required infrastructure upgrades to mitigate risks to the environment. Samples were collected from Caithness General Hospital (Wick, UK) and from separate stages of the receiving WWTP. Liquid chromatography-tandem mass spectrometry was used for quantitative analysis of eight compounds: paracetamol, diclofenac and ibuprofen (analgesics/anti-inflammatories), clarithromycin and trimethoprim (antibiotics), carbamazepine and fluoxetine (psychiatric drugs) and 17α-ethynylestradiol (synthetic hormone). Pharma concentrations were in the mid-high ng/L range, with the analgesics/anti-inflammatories and antibiotics detected in the highest concentrations. High resolution mass spectrometry was used for suspect-screening and non-target analysis to identify pharma degradation products and elucidate transformation behaviour within the WWTP. Removal efficiency was calculated from the influent and effluent concentrations, and indicated that the conventional treatment techniques employed are ineffective for pharma, most notably antibiotics. A risk assessment was carried out by comparing observed concentrations, eco-toxicity data and prescription rates in Scotland. This suggested that the compounds of most environmental concern are paracetamol, fluoxetine, diclofenac, clarithromycin and 17α-ethynylestradiol in our study, and source control may be the best preventative measure to reduce burdens on WWTPs and protect water quality. The distribution and degradation of these compounds in WWTPs and effluent-receiving surface water should be further investigated.

89

Occurrence and seasonal variation of pharmaceutical compounds from four therapeutical classes in the influents of two Portuguese wastewater treatment plants

J.E. Rodrigues, EPAL S.A. / Direção Laboratórios e de Controlo da Qualidade de Água - Department of Organic Chemistry; S. Silva, iMed.UL, Faculdade de Farmácia da Universidade de Lisboa; V.V. Cardoso, Empresa Portuguesa das Águas Livres, S.A. EPAL / Direção Laboratórios e de Controlo da Qualidade da Água; M.E. Cardoso, Águas do Tejo Atlântico - Departamento Laboratório de Águas Residuais; M.R. Coelho, Águas do Algarve Ada; M.J. Benoliel, Empresa Portuguesa das Águas Livres, S.A. EPAL / Direção Laboratórios e de Controlo da Qualidade de Água; C.M. Almeida, iMed.UL, Faculdade de Farmácia da Universidade de Lisboa

Pharmaceutical compounds (PhCs) are one of the major classes of emerging contaminants due to their intrinsic biological activity. Their presence, even in trace concentrations, raise the possibility of causing adverse effects on both aquatic ecosystems and humans due to chronic exposure. Although the occurrence of PhCs in the urban water cycle has been extensively studied, the understanding of the effects of conventional wastewater treatment processes on PhCs removal is still scarce. Wastewater treatment plants (WWTPs) are crucial barriers against PhCs, with their efficiency depending of several factors such as contaminants psychochemical properties, climate conditions, technology, operational conditions and contaminants concentration in the raw influents (WWI). Therefore, a detailed characterization of WWIs load is important and mandatory towards improving WWTP efficiency. In this work, a SPE-LC-MS/MS method was optimized and validated for the measurement of 24 PhCs (10 therapeutical classes) in WWIs from two Portuguese WWTPs: Beirolas and Faro Nw. Under project LIFE IMPETUS, a total of 41 sampling campaigns were performed between September 2016 and July 2018. These two WWTPs showed similar concentration PhCs profile, being the most representative therapeutical classes analgesics (acetaminophen, APAP), psychostimulants (caffeine, CAF), NSAIDs (diclofenac, DCF, ibuprofen, IBUP, and naproxen, NPX) and antibiotics (erythromycin, ERT, sulfadiazine, SDZ, sulfapyridine, SPD, and sulfamethoxazole, SMX). Based on these results, these therapeutical classes were the main focus of this work. Regarding seasonal behavior in Beirolas WWIs, median concentrations varied between 1.6 μg/L (antibiotics, winter 2017) and 87.2 μg/L (analgesics, winter 2018). Seasonal variations were observed in analgesics (APAP), antibiotics (mainly due to SDZ) and, in less extent, NSAIDs (mainly IBUP), particularly in autumn and winter seasons. Regarding Faro Nw WWIs, median concentrations varied between 0.95 μg/L (antibiotics, spring 2018) and 78.3 μg/L (analgesics, winter 2018). Seasonal behavior was subtler in Faro Nw, possibly due to milder climate conditions, and the variations were observed in analgesics (APAP) and, in less extent, antibiotics. For both WWIs, psychostimulants showed no clear seasonal variations. Overall, this approach enables a comprehensive overview of PhCs profile in WWIs, and consequently, giving relevant information towards improving the WWTPs removal efficiency.

Beyond freshwater ecosystems: bioaccumulation of emerging contaminants in plants growth in Saudi Arabia oasis impacted by wastewater

Y. Pico, University of Valencia / Environmental Quality and Soil; R. Alvarez-Ruiz, University of Valencia; M.A. El-Sheikh, King Saud University / Department of Botany and Microbiology, College of Science; A.H. Alfarhan, King Saud University; H.O. Alshahrani, King Saud University / Department of Botany and Microbiology, College of Science; D. Barcelo, ICRA / Department of Environmental Chemistry

There is increasing concern on food safety because of environmental pollution. Soil pollution with anthropogenic emerging contaminants (CECs) coming from urban areas, industry or agriculturel such as pesticide, fertilizers, pharmaceuticals, personal care products, illicit drugs has received much attention in recent year. CECs in soils can not only be biodegraded, but also bioaccumulated and biotransformed by plants, and pose toxicity beyond certain limit. This study aims at assessing the problem of environmental contamination in two areas of Saudi Arabia (Al-Hayer and Al-Asfar) heavily affected by the use of non-conventional water resources (mostly treated wastewater) through the assessment of these compounds in water, soil and sediments. Furthermore, the potential uptake and bioaccumulation of those CECs found in soil was also evaluated. To this end, pharmaceuticals (carbamazepine, ibuprofen, gemfibrozil, etc…), personal care products (parabens, bisphenol A, etc…) and pesticides (diazinon, chlorpyriphos, etc..) were determined using extraction with methanol and a solid-phase clean-up (SPE) followed by liquid chromatography-tandem mass spectrometry with a triple quadrupole (LC-MS/MS). Microplastics were also determined in water samples by filtration of 20 L though a 150 μm net. Once isolated in the filters, several treatments with oxidants and counting visually using microscope. The results pointed out the widespread contamination of water, soil and sediments by these CECs, including microplastics. The assessment of crops and other plant material showed that several CECs, including six pharmaceuticals (atenolol, caffeine, carbamazepine and its metabolites 10,11-epoxycarbamazepine, gemfibrozil, and naproxen) and seven pesticides (acetamiprid, atrazine deethyl, azoxystrobin, bupirimate, diazinon, malathion, pirimicarb and some of their metabolites) were detected in plants. Up to our knowledge, this is one of the pioneering studies demonstrating the CECs' accumulation in crops irrigated with treated wastewater under non-controlled environmental conditions. *Acknowledgement* – The authors thanks the financial support from the Distinguished Scientist Fellowship Program (DSFP) from King Saud University, Saudi Arabia. The mass spectrometry section of the SCSIE of the Universitat de València is also acknowledge for the help R. Álvarez acknowledge the Spanish Ministry of Science, Innovation and Universities for his FPI grant BES-2016-078612.

Determination of personal care products in wild fish bile using hybrid solvent precipitation and dispersive solid phase extraction cleanup with UPLC-MS/MS and GC-MS analysis

J. Zhao, South China Normal University; L. Yao, Guangzhou Institute of Geochemistry, Chinese Academy of Sciences; Y. Liu, South China Normal University / Environmental Research Institute; G. Ying, Chinese Academy of Sciences/South China Normal University / SCNU Environmental Research Institute

Personal care products (PCPs) are ubiquitous in aquatic environments owing to the continuous discharge of domestic wastewater from highly urbanized regions. These PCPs can be adsorbed by wild fish and thereafter usually enter the bile of the fish through biliary excretion. In this study, a quick and sensitive method based on a combination of hybrid solvent precipitation and dispersive solid phase extraction (d-SPE) purification was developed to simultaneously extract and detect 24 PCPs, namely, 16 biocides, 4 synthetic musks, and 4 benzotriazoles, from wild fish bile. Hybrid precipitation on solid phase extraction (SPE) tubes was applied to remove phospholipids and proteins, and a d-SPE procedure was used for further purification. The extraction solvents for the hybrid precipitation/SPE tubes and d-SPE materials were optimized. The method

performances for bile samples both with and without enzyme hydrolysis using β-glucuronidase/aryl-sulfatase were validated. The 24 PCPs in fish bile were spiked with standard concentrations of 10 ng/mL, 20 ng/mL, 100 ng/mL, and 200 ng/mL to evaluate recoveries, which ranged from 70–120% for 16, 16, 22, and 21 analytes with hydrolysis, respectively, and 70–120% for 14, 15, 23, and 23 analytes without hydrolysis, respectively. The quantification limits for target PCPs were in the range 0.26–6.45 ng/mL [excluding musk xylene (MX) and musk ketone (MK)] and 0.20–8.62 ng/mL (excluding MX and MK) for bile samples with and without enzyme hydrolysis, respectively. After enzyme hydrolysis, 12 PCPs were detected in bile from wild fish collected from the Yangtze River, with a maximum detected concentration of 460 ng/mL, for triclosan (TCS). The hydrolysis reaction indicated that high percentages of glucuronide and sulfate metabolites for some PCPs, four parabens, and TCS, existed in the bile.

92
Using column chromatography to assess mobility of natural toxins in the aquatic environment
C.D. Schoensee, Agroscope / Environmental Analytics; K. McNeill, ETH Zurich / Institute of Biogeochemistry and Pollutant Dynamics; S. Droge, University of Amsterdam/IBED Institute / IBED; T. Bucheli, Agroscope ART / Environmental Analytics
Over 34% of recently evaluated plant secondary metabolites (natural toxins) were found to fulfil the criteria for aquatic persistency, mobility and toxicity based on predicted property data.[1,2] However, as prediction tools show limited applicability,[3] experimental evaluation of the organic carbon-normalized sorption coefficient (K_{oc}) as a primary mobility parameter is a crucial step to determine if natural toxins end up in potential drinking water abstraction sites. Column chromatography was applied in the systematic evaluation of sorption behavior of a large diverse set of natural toxins to organic matter. Experiments were generally performed as described previously.[3] However, in this study the method was applied to a substantially larger set of compounds and experimental conditions varied to study effects of e.g., temperature and pH on K_{oc}. In addition, method performance parameters were evaluated to ensure method applicability. The case of natural toxins shows that column chromatography is a suitable method for quantitative, reproducible analysis of sorption to organic matter. It is generally applicable to large sets of mobile compounds (log K_{oc} between 0.5 and 3.5). According to the obtained data, most analyzed phytotoxins can be categorized as mobile in the aquatic environment with log K_{oc} values well below the defined cut-off criterion for mobility of log K_{oc} = 4.5.[2] Many toxins are also ionizable and appear in the more water-soluble cationic form in the environmentally relevant pH range and thus show even higher mobility. The very short analysis time and little material requirements easily allow systematic investigations of differing influences on sorption. Thus, detailed mechanistic insights are gained that are of great value for understanding transport and fate processes in the environment. Applying the method to other different sorbents in the future (e.g., minerals, activated carbon) will help to determine their individual contribution to the natural toxins' overall mobility on their path from source to tap (drinking water).

Your Science or my Science? When the Sides taken on a Research Topic are Impacted by Different Philosophical Positions and Values (I)

93
The Role of Philosophical Positions and Values in Scientific Controversies
K. Elliott, Michigan State University / Lyman Briggs College
Scientific controversies often stem from underlying philosophical disagreements. This talk will provide a starting point for the SETAC Special Session, "Your Science or My Science? When the Sides Taken on a Research Topic Are Impacted by Different Philosophical Positions and Values," by clarifying three major ways in which philosophical positions and values can impact scientific controversies. First, those involved in scientific controversies may hold different background assumptions, which result in differing interpretations of the available evidence. For example, recent controversies about endocrine-disrupting chemicals like bisphenol A (BPA) may stem in part from differing assumptions about how to interpret apparent evidence of effects at low doses that are not seen at higher doses. Second, controversies can stem from disagreements about levels or standards of evidence. For example, conflicting views about the toxicity of glyphosate appear to stem at least in part from disagreements about whether particular kinds of studies and trends in data provide sufficient evidence for its carcinogenicity. Third, controversies may stem in part from different ways of framing a problem situation. For example, conflicting views about the acceptability of genetically engineered crops may arise when some analysts are focused on human health effects while others are considering broader social impacts and alternatives. The talk will conclude by discussing ways of addressing these philosophical positions and values in a fruitful manner, both by communicating about them more effectively and by fostering forums in which they can be brought to light.

94
The use of pesticides should be critically considered: the emblematic case of neonicotinoids
J. Bonmatin, Centre National de la Recherche Scientifique
Research on pesticides and their impacts has increased in recent decades because of pollution and impacts generated by pesticides for the environment. Experimental data can be interpreted differently, depending on experimental design, sources (for example, unpublished studies and/or peer-reviewed studies), values and conflicts of interest. This can then influence decisions made on a scientific basis, or simply reduce the credibility of science. Is destroying biodiversity and ecosystems a sustainable strategy? Because research on neonicotinoid insecticides is one of the best documented, because these relatively new insecticides are used prophylactically (preventive treatment) and not as a last resort, neonicotinoids illustrate the issue of mass use of pesticides as opposed to sustainability. Science is often a contradictory process where data must be accumulated before a general consensus can be reached. Several meta-analysis are presented on these insecticides. They illustrate the impacts of neonicotinoids on biodiversity and ecosystem services. Paradoxically, these ecosystem services include the services needed for agriculture (for example, soil quality and pollination). Therefore, the current use of these pesticides needs to be critically examined. The assessment should not be limited to private and short-term benefits, but also to a more comprehensive approach which includes increasing pest resistance, limited resilience of the nature, and quality and richness of our environment. Agronomic alternatives must be favoured because they have proved their effectiveness in a vast majority of cases. In addition, it seems increasingly risky to claim that what destroys biodiversity would have no effect on our health.

95
Principles to enable farm productivity and conservation through modern crop protection
J.F. Gonzalez-Valero, Syngenta Crop Protection AG
Farmers today face many challenges from climate change, soil erosion and biodiversity loss to changing consumer expectations and views on agricultural technology. In particular the use of pesticides to protect crop quality, safety and productivity are challenged by many. There is an undeniable demand for a shift in crop protection, and a clear call for innovation and more action to address these challenges in ways where everybody wins – from growers to consumers and the environment. Arguably, crop protection products regulation has the highest levels of consumer and environmental safety and it has constantly evolved for more precautionary measure. Environmental Toxicology Science has evolved the safety of pesticides and the role they play in protecting food quality and safety. However, there is a strong believe that technology in agriculture is not needed and hence any safety and risk assessment will biased. At the same time, there is no agriculture without crop protection, be it mechanical, chemical- or biological-designed molecule based, or build in through genetics. All these technologies need to follow the same principles in order to be safe for humans and environment and to protect food quality and quantity: 1) provide solutions for safe and nutritious food, feed, fibers and fuels; 2) Improve soil health for climate-resilient agriculture; 3) Enhance human health and well-being; 4) Protect natural resources; 5) be developed in open communication and partnership to increase the shared value.

96
Promoting sustainable use of pesticides and innovation: the Finnish experience
T. Jern, Ministry of Agriculture and Forestry / Department of Food
Finland has a long history of sustainable use of pesticides. The Finnish authorization system has been strict and many old pesticides were phased out already in the eighties and in the nineties. We have statistics on pesticide sales since the early fifties. We have always had a low use of plant protection products and a low occurrence of pesticide residues, both in vegetable products and in surface and ground water. Our first action plan for a sustainable use of pesticides was, published in 2011. We focused on training and information. Our goal was to reduce the health risks from pesticide use through maintaining the good situation with pesticide residues and reducing the environmental risks of pesticide use by developing and steering pesticide use, so that the risk to the environment and to nature would be small. This included developing measures for water protection, promoting a more diverse crop rotation and fostering better practices in handling and storage of pesticides and remnants. We built a training system, which was voluntary for the users of plant protection products. The exam to show that the person really mastered the subject was compulsory. This way a professional user could acquire his/her knowledge either by attending a training course or in another way. The competent authority approved the providers of training and the exam organizers. The second great challenge was to renew the system for testing of application equipment. The first action plan was analyzed in 2017 and in 2018 our second action plan was published. The new program has the same goal – to reduce the risks from pesticide use - but it is more detailed, more ambitious and contains quantitative or qualitative goals. The new plan includes clear actions but also

reviews or assessments, that have to be done to clarify what sort of action needs to be taken. Both for the first and the actual action plan we have sought to involve as large an amount of stakeholders as possible to get them involved and committed to the work. By getting people involved, we hope to see a good commitment to the work, as it is our shared responsibility to achieve a sustainable use of pesticides.

Determination of cyclic volatile methylsiloxanes in German wild fish via a GC-ICP-MS/MS method

G. Radermacher, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Environmental Specimen Bank and Elemental Analysis; H. Ruedel, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Department of Environmental Monitoring; J. Koschorreck, Umweltbundesamt

Keywords: methylsiloxanes, cVMS, fish, retrospective monitoring Cyclic volatile methylsiloxanes (cVMS) are widely applied industrially produced chemicals. For example, cVMS are ingredients in personal care and household products. In addition, they are used as intermediates for silicon polymers. The general structure is a ring built of alternating oxygen and silicon atoms which are substituted with two methyl groups at each silicon atom. Due to their physical and chemical properties (e.g. high hydrophobicity, vapour pressures and Henry's Law constants, relatively long modelled and measured half-lives), cVMS have the potential for long-range atmospheric transport, environmental persistence and bioaccumulation in food webs. It has been shown that cVMS octamethylcyclotetrasiloxane (D4), decamethylcyclopentasiloxane (D5) and dodecamethylcyclohexasiloxane (D6) are present in freshwater fish from several countries (e.g. Canada, Norway and Sweden). In 2018, D4, D5 and D6 were listed as Substances of Very High Concern under the EU REACH regulation. Hence, the target of this study was to investigate the occurrence and distribution of D4, D5 and D6 in fillets of German freshwater (bream) and marine (eelpout) fish from major German rivers and the North and Baltic Sea, respectively. Samples of the German Environmental Specimen Bank (ESB) provide the opportunity to analyse time series. First, a solid/liquid extraction method with acetonitrile and hexane mixture was performed. Then, speciation and quantification of cVMS was carried out with a new GC-ICP-MS/MS coupling method. The application of the triple quadrupole technique allows the elimination of interferences, such as CO^+ or N_2^+ ions, on the main silicon isotope (m/z=28) by the use of hydrogen as reaction gas. D5 was found in all samples from the riverine sampling sites. Furthermore, the results show that D5 concentrations were clearly higher than the observed D4 and D6 concentrations. In total, the highest cVMS burdens were determined in samples from the river Saar. In contrast, at ESB reference sampling site Lake Belau as well as in eelpout muscle tissue from the North and Baltic Sea no cVMS were found.

99

Analysis and occurrence of organophosphate esters in fish

L. Han, China Agricultural University / College of Science; Y. Sapozhnikova, U.S. Food and Drug Administration / ARS

Organophosphate esters (OPEs) are high volume production chemicals used as flame retardants and plasticizers in many consumer and commercial products. OPEs have been reported in the environmental samples, *i.e.* indoor dust, air, wastewater, marine and river water, ground water, soils and sediments. Most published reports on OPEs' occurrence thus far focused on their levels in air, water, soil, sediments, biota, and humans, and several recent publications emerged on OPEs' occurrence in foods. The goal of this study was to develop a fast and simple method for analysis of the fourteen most commonly used OPEs in fish and apply the developed method for the analysis of fish samples from the USA markets to generate data on their occurrence. Fourteen OPEs selected in this study were: trimethyl phosphate (TMP), triethyl phosphate (TEP), tri-n-butyl phosphate (TnBP), tris (2-chloroethyl) phosphate (TCEP), tris (2-chloro-isopropyl) phosphate (TCPP), tris (1,3-dichloro-2-propyl) phosphate (TDCPP), cresyl diphenyl phosphate (CDPP), tri-cresyl phosphate (TCrP), tri-propyl phosphate (TPrP), tri-phenyl phosphate (TPP), 2-ethyl-hexyl-diphenyl phosphate (EHDPP), tris (2-butoxyehtyl) phosphate (TBEP), tris (2-ethylhexyl) phosphate (TEHP); tri-isobutyl phosphate (TiBP). The developed method was based on QuEChERS extraction, automated mini-SPE cleanup, and UHPLC- and fast low pressure (LP)GC-MS/MS analyses. 14 OPEs were analyzed by UHPLC- and 8 OPEs were analyzed by LPGC-MS/MS. Two isotopically labeled internal standards: TPP-d_{15} and TCEP-d_{12} were used. Method detection limits were 0.5 - 1 ng/g, and OPEs' ubiquitous presence in laboratory environment and materials presented a challenge to their accurate quantitation at levels below 1 ng/g, especially in LC- vs. GC-MS/MS analysis. The method was validated at four spiking levels (5, 10, 20 and 40 ng/g), and satisfactory recoveries (70-120%) and RSDs (< 20%) were achieved for 13 OPEs. The validated method was applied for analysis of different fish samples to generate needed data on OPEs occurrence in fish. TCPP was found in flounder, monk fish and catfish in concentrations 0.3-8 ng/g. More data on occurrence of these emerging contaminants are needed to advance our understanding of their potential risks and aid in future risk assessments and regulations.

Tracing microbial turnover of pesticides in water-sediment with stable isotope probing

K. Nowak, TU Berlin / Institute for Environmental Research (Biology V); S. Wang, Helmholtz Centre for Environmental Research UFZ / Dept of Environmental Biotechnology; A. Miltner, Helmholtz Centre for Environmental Research UFZ

Pesticides and their transformation products are frequently detected in freshwater sedimentary environments, but there are no comprehensive studies on their behaviour in these systems. Microorganisms can use C and N from a pesticide to synthesize their biomass compounds, e.g. amino acids. Their biomass compounds after the death can be stabilized in the organic matter of sediment forming harmless biogenic non-extractable residues (bioNER). The conversion of a pesticide to carbon dioxide and bioNER leads to their ultimate detoxification. The objective of this study was therefore to investigate the turnover of model pesticides (glyphosate and metamitron) in the water-sediment systems with a particular focus on its biodegradation pattern and bioNER formation using the ^{13}C and ^{15}N-labeling approach. Mineralization in water-sediment was much higher (55.7% of $^{13}C_3$-glyphosate and 49% of $^{13}C_6$-metamitron equivalents) than in the water only (2.4% of $^{13}C_3$-glyphosate and 4.9% of $^{13}C_6$-metamitron equivalents). This finding demonstrates the key role of sediments in pesticides' degradation. Nearly all ^{13}C and ^{15}N-NER from $^{13}C_3{}^{15}N$-glyphosate were biogenic NER, whereas 83% of ^{13}C-NER from $^{13}C_6$-metamitron were bioNER. The presented data provide the first evidence of the utilization of glyphosate as a carbon and nitrogen source and metamitron as carbon source. ^{13}C (and ^{15}N-label) incorporation into amino acids revealed that both pesticides were degraded into two different pathways.

101

Environmental Fate of Antimicrobial peptides

C.A. Davis, ETHZ / Eawag / Department of Environmental Chemistry; E. Janssen, Eawag / Environmental Chemistry

Due to resistance formation towards conventional antibiotics, antimicrobial peptides (AMPs) are becoming increasingly important as a last resort against multi-drug resistant bacteria. The World Health Organization has reclassified some AMPs as critically important for human medicine in 2011. However, many AMPs had been introduced to the market before environmental risk assessment was required, e.g., by the European Medicines Agency (EMA) since 1998. While, polymyxins and bacitracin have been administered as antibiotics and growth promotors in the feedstock industry since the 1960sand were reconsidered for human medicine by EMA in 2013, their mobility and persistence in the environment remains unknown. In this study, we investigate the environmental fate of three commonly used AMPs: bacitracin, daptomycin, and polymyxins B and E (Colistin). We find moderate affinity of anionic daptomycin to sorb to standard European soils (K_d=20.6 – 48.6), while the cationic polymyxins bind irreversibly. Assuming moderate mobility for some AMPs and potential to be flushed out by run off events, we further investiated photochemical and microbial transformation processes in surface waters. We demonstrate that daptomycin has a photochemical half life of 7 hours, predominantly driven by direct phototransformation (48%), reaction with singlet oxygen (19%), and with excited triplet sensitizers (up to 33%). Polymyxins have shorter half-lives (1.5-2.0 h) predominantly driven by indirect photochemical processes. Ongoing test further suggest that biotransformation by riverine biofilm can play a key role in the fate of AMPs. Our findings of sorption behavior, photo- and biotransformation rates together will reveal the overall persistence of AMPs in the aquatic environment. Keywords: Antimicrobial peptides, photodegradation, biotransformation

102

Natural Bromophenolic Compounds in Nordic Macroalgae

T.F. Bidleman, Umea University / Department of Chemistry; A. Andersson, Umea University / Department of Ecology and Environmental Sciences; S. Brugel, Umea University / Dept. of Ecology and Environmental Sciences; L. Ericson, Umea University / Department of Ecology and Environmental Sciences; P. Haglund, Umea University / Department of Chemistry; D. Kupryianchyk, Umea University / Department of Chemistry Biochemistry; D.C. Lau, Umea University / Department of Ecology and Environmental Sciences; P. Liljelind, L. Lundin, M. Tysklind, Umea University / Department of Chemistry

Macroalgae are used worldwide for human food. They are a rich source of vitamins, minerals, fibre, phytochemical antioxidants (fucoxanthin, polyphenols) and omega-3s, and many health benefits are attributed to their consumption [1]. Bromophenolic compounds (BPCs) are commonly found in marine algae. BPCs comprise bromophenols (BPs) and transformation products bromoanisoles (BAs), hydroxylated and methoxylated bromodiphenyl ethers (OH-BDEs, MeO-BDEs) and polybrominated dibenzo-*p*-dioxins (PBDDs). BPCs enter the human diet through macroalgae consumption and from BPCs bioaccumulated in seafood. Profiles of MeO-BDE congeners in human serum reflect dietary exposure [2]. Toxic properties associated with BPCs include hormone disruption (OH-BDEs and MeO-BDEs) [3] and inhibition of oxidative phosphorylation (OH-BDEs) [4], and binding to the aryl hydrocarbon receptor (PBDDs) [5]. BPCs are accumulated in the Baltic food web [6,7]. In 2017-2018, we collected macroalgae from the Bothnian Sea (northern Baltic), Swedish west coast (Skagerrak) and Norwegian coast to determine the variability of BPCs among species and locations and estimate the role of macroalgae in supplying BPCs to Nordic estuaries. Compounds identified in 18 species (red, green and brown) were 2,4-DiBA, 2,4,6-TriBA, 2'-MeO-BDE66, 6-MeO-BDE47, one tetrabromo- and two tribromo-MeO-BDEs with unknown substitutions. Concentrations (pg g^{-1} wet wt.) varied over several orders of magnitude: 62–41000 for Σ_2BAs and < 15–490 for Σ_5MeO-BDEs. Higher concentrations were generally found in brown algae *Ascophyllum nodosum* and *Fucus spp.* The wide range of BPCs in macroalgae and strong seasonal variations [6] are important factors in controlling sources to estuaries and bioaccumulation, and for human consumption. Remediation of Contaminated Environments and Innovative Methods in Biological Strategies (II)

104
Biodegradation of cylindrospermopsin by manganese oxidizing bacteria
E. Martínez Ruiz, Technische Universität Berlin / Institute of Environmental Science & Technology; M. Cooper, Technical University Berlin; J. Fastner, UBA Umweltbundesamt / Section Drinking Water Treatment and Resource Protection; U. Szewzyk, Technical University Berlin / Chair of Environmental Microbiology
Cyanobacterial blooms pose a high risk to the health of humans and freshwater organisms due to the potential production of cyanotoxins. Cylindrospermopsin is an alkaloid toxin commonly found in freshwater bodies and is toxic to humans and other organisms. In natural environments, concentrations have been found between 0.2 to more than 200 $\mu g\ L^{-1}$. So far, little is known about the biological degradation of cylindrospermopsin. Manganese oxidizing bacteria (MOB) are capable of transforming a variety of organic and inorganic pollutants. However, their potential for biodegradation of cyanotoxins, as cylindrospermopsin, has not been assessed yet. Therefore, cylindrospermopsin degradation via different neutrophilic aerophilic MOB isolated from natural and technical systems was investigated. Tested MOB's included one *Pseudomonas* sp. strain, two *Leptothrix* sp. strains, and one *Ideonella* sp. strain. In addition, we assessed the influence of different parameters such as the presence of iron, yeast extract and manganese on the degradation of cylindrospermopsin. The concentration of oxidized manganese, as well as cylindrospermopsin removal by biogenic oxides alone was also evaluated. *Pseudomonas* sp. strain OF001, degraded about 100% of the toxin in three days. The highest degradation efficiency was measured when $MnCO_3$ was used as manganese source for the MOB in the media, ranging from 25 to ~100% of cylindrospermopsin removal and degradations rates of 1.13 – 37.01 $\mu g\ L^{-1}\ day^{-1}$. In the absence of manganese, the degradation was null or lower than 20%. The concentration of oxidized manganese in the medium did not influence cylindrospermopsin degradation, showing that the mere active oxidation of manganese is important without considering how much biogenic oxides they produce. Cylindrospermopsin degradation by biogenic oxides, in the absence of viable cells, was low or non-detectable. Considering the efficient removal of cylindrospermopsin by the tested strains, manganese oxidizing organisms could play an important role in cylindrospermopsin degradation. In addition, MOB could be promising candidates for future enforcements for biodegradation of cylindrospermopsin in water treatment plants.

105
Humic products for soil remediation technologies: chemical properties and biological activity
O. Yakimenko, Moscow State University / Soil Science Faculty
Humic products (HP) produced by companies from various organic materials, are being increasingly used in soil remediation. Depending on organic source material (lignite, peat or composts), humic acids (HA), which are considered to be the active ingredient in HP, are different in chemical structure and in their efficiency as plant growth promotors and soil conditioners. The objective of the study was to evaluate in a number of laboratory, pot and field experiments the potential of HP as plant growth stimulators for agriculture and as remediating agents for contaminated soils. Chemical properties of a number of lignite-, peat- and lignosulphonate- derived HP (elemental content, IR-spectra, absorption and fluorescence spectra) are analysed. Biological activity of the same HP are examined in laboratory and field experiments using various endpoints: plant biometry, soil chemical and biochemical parameters, bioassays with battery of test-cultures, effect on yield and crop quality in field trials. Potential of HP to decrease content of available species of heavy metals in contaminated soils is evaluated in case studies. Several approaches to assess the effectivity and "integrated environmental quality" of HP are tested and compared using detoxication coefficient, Triad method, and Harrington desirability function. The organic matter genesis is the key factor influencing composition and structure of HA in HP. HA from fossil coal are more aromatic, hydrophobic, contain fewer functional groups and mobile low-molecular components. Peat-derived HA are the most aliphatic, hydrophilic and enriched with amino acids and carbohydrates. Using absorption and fluorescence spectra one can discriminate organic matter source for HP from lignite, peat and lignosulphonate. Bioassays showed that HP could provide both stimulationg and inhibiting effect, depending on sensitivity of test-culture, experimental design, nature and properties of HP. In laboratory tests most of analyzed HP promoted development of roots and shoots, stimulated fluorescence of algae and affected activity of some soil enzymes at 10-100 mg/L. In field trials, preplant seed treatment with HP affected plant resistance to chemical products. In heavy metal contaminated soils application of HP decreased the toxic effects of Cu, Pb and Cd on plants. Integrated "environmental quality indicators" showed that HP at rates 0.0025 and 0.01% are able to reduce ecological toxicity in urban soils The study was supported by RFBR, grant 18-04-01218_?

106
Antioxidant activity and toxic properties of humic substances. Evaluation via bioluminescent enzymatic assay
N. Kudryasheva, Institute of Biophysics SB RAS Federal Research Center Krasnoyarsk Science Center SB RAS; A.S. Sachkova, Tomsk Polytechnic University / School of Nuclear Science & Engineering; E.S. Kovel, Institute of Biophysics SB RAS, Federal Research Center Krasnoyarsk Science Center SB RAS
Bioluminescent methods are widely used to monitor toxicity of media due to high rates of the assay procedure and simple registration of the luminescent signal. These features provide a large number of measurements under comparable conditions, which is extremely important for statistical processing. The classic bioluminescent bioassay is based on luminous marine bacteria; it has been widely used for more than 50 years to assess a toxicity of aquatic environments due to high sensitivity to pollutants. A suppression of maximal bioluminescence intensity is a quantitative characteristic of general (integral) toxicity of the environment. Recent decades, a new type of bacterial bioluminescence assay develops. It is based on a system of coupled enzymatic reactions of luminous bacteria, namely, two reactions catalyzed by bacterial luciferase and NAD(P)H:FMN-oxidoreductase. A particular feature of this bioassay is specificity to the group of toxic agents of oxidative nature: additionally to reducing maximum luminescence intensity, a bioluminescence delay period occurs; it depends non-additively on the oxidizer' concentration and redox potential. This feature is a basis for monitoring the oxidative toxicity of the environment. Hence, the bioluminescent enzymatic bioassay can be used to determine both the General Toxicity (*GT*) of high-concentration solutions of bioactive compounds (involving humic substances, *HS*) and their ability to change Oxidative Toxicity (*OxT*) of the media, i.e. their antioxidant activity. Toxicity and antioxidant activity of *HS* was studied in a wide range of their concentrations using the enzymatic bioluminescent bioassay. Chemical and biological aspects of the effects are under consideration. The antioxidant activity was demonstrated at low *HS* concentrations. Toxicity of the *HS* solutions was evaluated with effective concentrations *EC-50*; detoxification coefficients D_{OxT} and D_{GT} were used to evaluate antioxidant activity in solutions of organic and inorganic oxidizers. The toxicity and antioxidant activity of *HS* was compared to those of the other bioactive compound, fullerenol-60 (*F*). Differences in the effects of *HS* and *F* were related to (1) the mobility of functional groups and fragments of *HS*, (2) their high ability to reduce the content of reactive oxygen species in solutions. \n The work was supported by the PRAN-32, grant of RFBR N18-29-19003mk

Structure and dynamics of microfungal communities in soils with different humus content under polymetallic pollution
E.V. Fedoseeva, Pirogov Russian National Research Medical University / Pediatric faculty; A. Ivanova, N. Verkhovtseva, Lomonosov Moscow State University; V. Terekhova, Lomonosov Moscow State University / Lab of Ecotoxicological Soil Analysis
Heavy metals (HM) pollution is a priority negative impact on soils. The sorption of HM cations by soils, and consequently the toxicity of these pollutants, depends on soil properties including humus status. Structural indicators of fungal

communities and proportion of melanin containing species can be considered as the most informative for certain kinds of anthropogenic impacts. The humus status of soils can be modeled by the introduction of carbon containing compounds. The aim of the study was to characterize the structure and dynamics of fungal communities under polymetallic pollution in soils with different humus content without and with carbonaceous amendments. The two types of soils were taken for the experiment: chernozem and agrozem (organic carbon content 5.5±0.02% and 1.5±0.02%, respectively). Dry mixture of HM (Zn, Cu and Pb) was added to soil samples. Then the amendments were applied: 5 % biochar in dry form, 0.25 % lignohumate in the form of an aqueous solution, and their mixture. Thus, 8 experimental variants were formed for each type of soil. The inoculation of microfungi from each experimental variant was carried out on three nutrient medium. Accounting of colony forming units (CFU) and taxonomic identification of spore forming forms was carried out. Also the assessment of microbial community structure differences in polluted and amendment soils samples were conducted by means of lipid analysis. At the beginning of the experiment, only minor fluctuations in fungal species diversity, which were little dependent on the type of soil, were revealed. Microfungal communities have undergone a transformation during the exposition. The dynamics of the taxonomic composition and the number of CFU differed in soils of different humus status. We can assume that at the end of the exposure: 1) species diversity of microfungi increased in the both types of soils, but it was higher in agrozem samples; 2) polymetallic pollution had a stressful effect, resulting in an increase in the number of species in the most experimental variants, especially in chernozem samples. According to results of lipid analysis the fungal biomass of dark-colored *Aspergillus* sp. increased sharply under HM in agrozem, and it decreased when the samples were carbon enriched after treatment with biochar and lignohumate. On the contrary, in humus-rich soil - chernozem, the effect of both TM and amendments was not so noticeable. The study was supported by RFBR, grant 18-04-01218_?.

Electrophoresis of soil humic acids - the key tool for revealing of their structural organization
O. Trubetskoj, Russian Academy of Sciences; O. Trubetskaya, Institut of Bioorganic Chemistry RAS
Electrophoresis of soil humic acids – the key tool for revealing of their structural organization Oleg Trubetskoj[a], Olga Trubetskaya[b] [a]Institute of Basic Biological Problems, RAS, 142290, Pushchino, Moscow region, Russia [b]Branch of Institute of Bioorganic Chemistry, RAS, 142290, Pushchino, Moscow region, Russia E-mail: olegi03@yahoo.com **1. Introduction** One of the electrophoretic approaches, which have been successfully used for humic acids (HAs) study, is polyacrylamide gel electrophoresis (PAGE) where distinct electrophoretic zones (EZ) were observed. On the other hand by using practically all known analytical techniques a huge number of individual molecular structural components were detected in HAs and they are unlikely could represent only a few distinct EZ of soil HA. On this reason the question concerning to EZ of soil HA is - what they are present itself? **2. Objectives** Twelve soil HAs of different genesis were the objectives of present study. **3. Materials & methods** Trubetskoj et al. (1991) has developed the new method of PAGE in the presence of denaturating agents which allowed separation of soil HA into quite reproducible distinct EZ. The coupling PAGE with SEC allowed to obtain preparative quantities of EZ from different soil HAs (Trubetskoj et al. 1999). Only after application of coupling SEC-PAGE for fractionation of soil HA the study of physical–chemical properties of their EZ was possible. **4. Results** We followed systematically this method over the last twenty years with different analytical tools and this allowed us to obtain physical-chemical characteristics EZ of different soil HAs with clear differences in terms of (1) electrophoretic mobility, (2) molecular size, (3) fluorescence and UV-vis spectra, (4) humic-like and protein-like fluorophores distributions, (5) amino acids weight content, (6) plant and/or microbial long chain fatty acids content, (7) aromatic/aliphatic components ratio, (8) hydrophobicity, (9-10) photosensitizing and phytohormone-like activities. **5. Conclusion** EZ of soil HAs independently on the soil origin consist of predominantly aromatic or aliphatic structures and possess different physical–chemical properties. It seems similar marked fractions have similar structural organization. Findings are consistent with the hypothesis that the structure of soil HAs arises through supramolecular assembly of different compound. **Acknowledgements** The work has been supported by RFBR (project 18-016-00078?).

Selection of amendments to decrease the mobility and toxicity of inorganic pollutants (Pb, As, Ba, Zn) in a mine tailing for the development of a phytoremediation process
M. Norini, ISTO; H. Thouin, BRGM; L. Le Forestier, P. Gautret, ISTO; M. Motelica, ISTO / ISTO; L. De Lary De Latour, BRGM; F.F. Battaglia-Brunet, BRGM / Water, Environment and Ecotechnology Division
In mining sites, the alteration of tailings induces a risk of dispersion of toxic elements, in addition with potential pollution of groundwater and surface water through leaching. The development of a vegetal cover is one of the potential options to decrease the risks. However, the growth of plants on mine tailings is generally hampered by several parameters: acidity, lack of nutrients, poor texture and toxicity of metals and metalloids. Thus, amendments are necessary to overcome these limitations. A mine tailing material was sampled on a former silver and lead mining site. Chemical analysis indicated the following concentrations in pollutants: 26 432 mg.kg^{-1} Pb, 265 mg.kg^{-1} Zn, 1 063 mg.kg^{-1} Ba, 1134 mg.kg^{-1} As. The tailing is acidic, siliceous and coarse (76% of particles with size in the range of 315 μm - 2 mm). A cow manure and some ochre (iron oxide-hydroxide) material produced in the water treatment plant of a coal mine were tested, alone or in combination, to stabilize the most mobile toxic pollutant, Pb, while avoiding the mobilization of other toxic elements. Leaching and microcosm experiments were performed and showed that the Pb concentration in water, that was higher than 10 mg.L^{-1} with the not-amended tailing, was decreased by a factor ×100, while As, Zn and Ba concentration did not increase significantly. Ochre (added at 5% in weight/weight) allowed increasing pH and could adsorb some metals and metalloïds. The metabolic microbial diversity, evaluated using Ecolog® plates, was improved by all amendements after one month of incubation. Polymers were the most used substrates in the non-planted microcosms, after one month of incubation, suggesting a specialized microbial community. Planted microcosms revealed that the growth of ryegrass was significantly improved by the addition of ochre and manure : the biomass of ryegrass is 3.5 X (with 5% ochre and 2% manure) to 4.8 X (with 5% ochre and 0.15%) greater than in the condition of plants growing on unamended soil. The next experimental step will include the monitoring of phytostabilization at metric scale, in mesocosm, with a vegetal specie naturally present on Pontgibaud mine site, belonging to the *Agrostis* genus.

Approaches to address variability and uncertainty in PBT and risk assessment of Petroleum substances
A.D. Redman, Exxon Mobil Biomedical Sciences, Inc. / Toxicology and Environment Science Division; C. Hughes, Ricardo Energy & Environment / Chemical Risk; Y. Verhaegen, CONCAWE; E. Vaiopoulou, European Petroleum Refiners Association; T. Parkerton, ExxonMobil Biomedical Sciences Inc. / Toxicology & Environmental Science
1. Introduction Risk assessment of petroleum substances is complicated by the variable and complex nature of the composition of the substances. Analytical characterization methods used to characterize composition vary based on project needs as well as the nature of the substance. The analytical techniques for complex substances often are challenged to definitively identify every constituent in a substance, which introduces some uncertainty into the risk assessment process. Environmental fate and toxicity properties also vary by chemical class and carbon number and is characterized by using representative structures with known, or estimated, physicochemical properties. Risk assessment frameworks need to be flexible to account for these variable analytical inputs and compositional variability. Existing risk assessment frameworks use the hydrocarbon block method to reduce variability and uncertainty. Variabilty is assessed by applying risk assessment models across broad datasets to understand the extent of variation between and within categories. Uncertainty in risk assessments is accounted for by comparing toxicity and risk simulations using estimated structures, compared to empirical toxicity data, and conservatively derived predicted no effect thresholds (PNEC). Further, uncertainty is further addressed through the use of conservative emission factors that can greatly over-estimate true emissions. 2. Materials and methods The hydrocarbon block method used for several decades and recent applications rely on finer blocks corresponding to avaible analytical chemistry in the PETRORISK model [1], and has been used in the PETROTOX model for toxicity prediction of petroleum substances [2, 3]. Both models use the toxicity thresholds established in the Target Lipid Model [4]. Application of these models to a wide range of petroleum substances provides an indication of the variability that is observed between substance categories, sources, seasons, and other factors that can affect substance composition. Uncertainty in PBT assessment was evaluted by comparing model predictions to available acute and chronic toxicity data for petroleum substances and through comparison to the PNECs [3]. 3. Results and discussion Variability exists in all model frameworks as a general rule. The impact of the variability on toxicity predictions for risk assessment is minimized by using statistical extrapolation techniques to estimate conservative PNECs. The PNECs are validated against available chronic toxicity data. 4. Conclusions In case of PBT assessment we advocate that uncertainty should be addressed using weight of evidence evaluation using multiple lines of evidence, and especially higher tier evaluation data. This would improve transparency and predictability in the decision making process. Otherwise, the inconsistent use of data and lack of WoE will effectively mis-prioritize chemicals limits the ability of industry to generate reliable data to support sound risk assessments. 5. A proposed Method of Determining Environmental Risk of Complex Substances
P. Thomas, CEHTRA SAS / Ecotoxicology and Risk Assessment; P. Bicherel, KREATiS
1. Introduction Methodologies for Environmental Risk Assessment (ERA) for single substances have been well established in the EU for some time. However, these assessments are not designed to be perfect, tend to conservatism, include non-science-based assessment factors to account for uncertainty and cannot depict with precision the real fate of a chemical. Current ERA methodology uses assumptions and approximations, e.g. extrapolation of hazard and risk to the sediment compartment from the pelagic compartment. Because the studies of toxicity to sediment-organisms are difficult to perform and are only required for higher tonnage bands, the concept of equilibrium partitioning (EP) is used and this relies on the hypothesis that the toxic effect concentration attributed to the most sensitive aquatic invertebrates can also be applied to benthic and terrestrial species as the pore water concentration. Despite this, the EU ERA method for chemical substances is considered as a useful tool by regulatory ecotoxicologists and substances with a RCR less than 1, are generally deemed of low concern for the environment. However, the EU risk assessment methodology is designed only for mono-constituents while many chemical substances falling under REACH regulation are multi-constituents or substances of UVCBs. Should every constituent be taken into account, and if so, is there a point at which their influence is limited? Is there a way in which the mixture is treated as a whole without overloading dossiers with multiple risk assessments? Aquatic toxicity of mixtures can be experimentally assessed using water-accommodated fractions (WAF) for partially soluble multi-constituent substances. In a WAF study the different constituents of the mixture are tested together at several loading rates. Toxicity is expressed as a single value of loading rate for the whole mixture. However, a toxicity result derived from a WAF study cannot be directly transposed to sediment or soil hazard and risk limiting the possibilities of performing an ERA for other compartments than the aquatic toxicity by the EP method as is traditionally carried out for single substances. KREATiS recently developed a calculation method for WAFs which has been supported by numerous experimental studies and which provides a mechanistic explanation for the WAF results using a thermodynamic approach. In this presentation, we consider moving a step further using a complementary blend of the WAF calculation and the Di Toro method in order to calculate Predicted Environmental Concentration (PEC) and Predicted No Effect Concentration (PNEC) values that have the same units (chemical activities) and allow the calculation of RCRs for mixtures in all environmental compartments. 2. Methodology The methodology proposed is divided into 3 main steps: hazard (acute and chronic) of the mixture for aquatic organisms and for benthic organisms has to be determined. exposure is determined in the aquatic compartments for each constituent using the standard methodology proposed in the ECHA guidance dedicated to environmental exposure. hazard (as PNEC) and expsoure (PEC) are converted into Predicted No Effect Activity (PNEA) and the Predicted Exposure Activity (PEA) of a mixture in the different compartments to give the RCRs per compartment As an example, an artificial equimolar mixture was formulated using an equimolar mixture of the 4 constituents. The constituents were selected ranging from slight to high hydrophobicity to achieve a relatively heterogenous distribution between water and sediments (such differences are typically observed in essential oils). Acute and chronic toxicity values to *Daphnia magna* and *Lumbriculus variegatus* have been measured according the OECD guidelines 202, 211 and 225. 3. Results and discussion Experimental tests and calculations were performed to determine the hazad of the mixture. The results showed that the toxicity (acute and chronic) obtained with WAF assays is predictable using a calculation method. Moreover, they showed that extrapolation from pelagic to benthic organisms (as suggested by Di Toro *et al.*) is still relevant for mixtures. 4. Conclusion The relevant ERA for mixtures is feasible by combining an *in silico* generated whole-substance approach (based on individual constituents) to determine the toxicity for pelagic organisms with the EP method to extrapolate effects on benthic organisms. The exposure is determined in each compartment using the EP method per constituent. Finally an activity-based approach is proposed to normalise the relationship between the toxicity and exposure by each constituent in order to determine a homogenous RCR for mixtures in the aquatic compartment using the same units.

UVCB fate-directed toxicity testing and risk assessment (UVCB-FATETOX)
P. Mayer, K. Sjøholm, N. Lam Trac, R. Hammershøj, Technical University of Denmark / Department of Environmental Engineering; P. Leonards, VU University, Institute for Environmental Studies / Department of Environment and Health; M. MacLeod, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES
UVCBs are substances of unknown or variable composition, complex reaction products or biological materials. UVCB substances consist of many different chemical constituents, some which may be unknown. Examples include petroleum substances, chlorinated paraffin's (CPs), flavoring agents, essential oils & their derivatives, natural oils and extractives, and biofuels. Assessing the environmental and human risks posed by UVCB substances is a challenge currently confronting chemical industry and regulators. This research project focuses at the toxicity and bioaccumulation testing of those UVCB constituents that are persistent. The objectives are (1) to develop approaches for fate-directed ecotoxicity assessment of UVCBs based on new analytical methods, dosing methods, fate directed fractionation, toxicity testing and models, (2) to conduct a case study on selected UVCBs and develop a generic risk assessment strategy for UVCBs and (3) to cross fertilize and partially align ongoing research activities at three European research institutes. The first work package focuses at combining state of the art dosing & analytical techniques with UVCB fate testing and includes (a) Passive dosing by polymer water partitioning & application to toxicity testing, (b) Aquatic biodegradation testing at environmental low concentrations coupled to advanced analytical instruments and (c) Bioaccumulation testing of UVCB mixtures coupled to Headspace-SPME and purge-and-trap. The second work package focuses at fate directed ecotoxicity and bioacumulation testing and includes (d) A literature review on fate-driven toxicity testing, (e) Aquatic toxicity testing with and without fate directed pre-treatment, (f) Bioaccumulation testing linked to biodegradation pre-treatment and (g) Linking toxicity to equilibrium concentrations in polymer and lipid – baseline versus excess toxicity.

113
Risk management of inorganic UVCB substances in the metal sector
F. Iaccino, Arche consulting; F. Verdonck, ARCHE; V. VEROUGSTRAETE, Eurometaux / EHS
A typical metal's lifecycle is made of a number of extraction and refinement processes, along which metals can be found in 'mixture' with other metals and mineral constituents embedded in a matrix or in a crystalline structure (e.g. of a pigment), as part of articles used for recovery or constituents of e.g. slags at the end of the refining process. These metal-containing materials represent significant volumes in the European market and an accurate risk assessment is essential to ensure that any potential environmental and health risk associated with their production, transport, storage and use is properly managed. Under the REACH Regulation, these substances are identified as UVCBs or substances of Unknown or Variable composition, Complex reaction products or Biological materials. Typically, their uncertaintyis linked to the analytical identification of some constituents' speciation (despite the elements in the composition are known and can be accurately quantified), whereas the variability is revealed by the broad concentration ranges for various constituents. Since 2013, Eurometaux is working on the development and implementation of an appropriatemethodology for the assessment of the inorganic UVCBs in the metals sector, i.e. from substance identification to risk assessment and risk management measures (RMMs) designation. The management of the risks posed by these materials, which is the ultimate goal of the REACH assessment, necessitates the identification of any possible hazard and assessment of exposure; however, testing eco/toxicity on the substance itself encounters several limitations considering the variability in the composition and the difficulty in identifying a set of representative and conservative samples. A constituents-based approach was therefore developed. In a nutshell, human health and environmental toxicity is considered to be driven by the toxicity of the UVCB constituents. To account for the uncertainty and variability, a precautionary approach is used along the different stages of the risk assessment by assessing reasonable worst-case speciation concentration. For the hazard classification, rules defined for the hazard assessment of mixtures under the UN Globally Harmonised System (GHS) and the EU Classification Labelling and Packaging (CLP) are applied. The MeClas (www.meclas.eu) web-based tool is used to ensure transparency in data selection, processing and reporting, compliant with GHS and CLP requirements. It used for hazard identification and classification of complex inorganic materials like UVCBs or others, based on the hazard of their constituents and on higher tier refinements, when e.g. bioavailability correction are available. Hazard classification for local effects leads to specific risk management measures. Similarly, the effect assessment for systemic and environmental effects is based on the specific assessment of the UVCB individual hazardous constituents, for which the risk assessment is conducted separately (and REACH registrations already exist) and on their (possible) combined effect. The exposure, risk assessment and hence selection of risk management measures is often based on representative measured data of their constituents, which are integrative of exposure to multiple UVCB substances at an industrial site. This reduces the level of uncertainty in the assessment and captures the variability in the composition. Common risk management strategies for the environment are for emissions to air: (wet) electrostatic precipitators or cyclones or fabric/bag filter or ceramic/metal mesh filter; for emissions to water: chemical precipitation or sedimentation or filtration or electrolysis or inverse osmosis or ion exchange. Emission to waste are low given the high internal or external metal recovery/recycling in the sector. Common risk management measures for the occupational exposure are use of fully or partially closed systems, integrated or

exterior local exhaust ventilation and capture sprays or wet suppression techniques.

New sampling strategies for optimised microplastic analysis in surface waters
U. Braun, BAM- Federal Institute Materials Research and Testing / 5.3 Mechanics of Polymers; K. Altmann, P. Eisentraut, Bundesanstalt für Materialforschung und -prüfung; A. Barthel, C. Bannick, Umweltbundesamt; M. Ricking, UBA Umweltbundesamt; M. Reiche, Umwelt-Geräte-Technik GmbH
The occurrence of microplastic particles (MP) in nearly every environmental compartment but especially in water is well documented in an increasing amount of publications released within the last few years. However, a comprehensive understanding of MP occurrence, sources and pathways in the environment as well as effects of MP on the environment are still unclear. Furthermore, the existing methods are often very time consuming, need high user knowledge and labour force, which is often not acceptable for a routine monitoring of an action or legal regulations. The calls for harmonised methods become loud and louder and promising efforts are made in this area. However, the scientific discussion is often focused on advantages and disadvantages of detection tools and sample preparation, less initiative is given to the sampling methods. That is a pity, because every environmental scientist knows, reliable analytical results depend on a good sampling method. At first glance, the collection of samples from aqueous systems seems easy because the sampling process already includes a content of the MP by means of sieves and filters. However, this filtering of water is often limited by the development of filter cake on the sieves, consisting of high amounts of natural particular matter. Hence often a small water volume is filtered, which will not contain a representative amount of trait carriers. Alternatively, complex sieves cascades are used which need complex technical equipment. Recently, we presented a fast thermoanalytical method for the detection of polymer fractions in water samples. This method, thermo-extraction desorption gas chromatography mass spectrometry (TED-GC-MS) can analyse MP in water filtrates without sample preparations within 2-3 hours. Advantageously, rubber particles from tires besides the MP can be analysed simultaneously. In order to become even faster we now start to develop new sampling strategies, which should be usable for different water systems. It is intended to reduce the effort in the field and to elongate times for integrative sampling to obtain representative result without random effects. In the present presentation we will show first result using a sedimentation box for sampling of MP from surface water. Advantages and disadvantages will be discussed and comparison to data derived from conventional fractionated filtration will be given.

116
Synthesis of metal doped nanoplastics and microplastic fibers and their utility for investigating plastic fluxes in complex matrices
S. Frehland, R. Kaegi, Eawag - Swiss federal Institute of Aquatic Science and Technology / Process Engineering; R. Hufenus, Empa Swiss Federal Laboratories for Materials Science and Technology; D.M. Mitrano, Eawag - Swiss federal Institute of Aquatic Science and Technology / Process Engineering
Reports on the occurrence of particulate plastics (nano- and microplastic particles and fibers) in the environment emerge on a weekly basis, but quantitative data are still limited due to analytical difficulties and inconsistencies of the methods applied to detect particulate plastics in complex environmental matrices. While progress is still ongoing to develop analytical methods to measure particulate plastic in field studies, researchers who study the fate, transport and biological interactions and effects of nano- and microplastics in bench top or pilot scale studies can take advantage of an entirely different approach. In this work, we synthesized a variety of particulate plastics (nanoplastic particles, fibers) with an embedded inorganic fingerprint (Pd or In; approx. 0.5% metal/wt) which can be used to detect plastic by common analytical techniques for metals analysis, such as ICP-MS. This allows us to more quickly and quantitatively assess plastic in complex matrices than is currently possible wit h other analytical techniques. To highlight the utility of this approach, here we used these materials to investigate the fate and transport of particulate plastic in a pilot-scale WWTP representing the activated sludge process. Triplicate samples were taken from the mixed liquor and effluent at least twice a week for the entire length of the experiment, which lasted five weeks. With a recovery rate of plastics over 90%, our findings show that over 98% of plastics (both nanoplastic particles and microplastic fibers) were found in the sludge, with a high correlation between TSS concentration and plastic concentration. Therefore, these materials will be removed from the wastewater stream with the sludge. While surveys of municipal treatment plants have shown similar trends in the magnitude of microplastics removed, we can now validate the retention of nanoplastics and microplastic fibers with a more complete mass balance study. With a better understanding of emissions from WWTP, one could suggest estimated annual loads of particulate plastics to surface waters or applied to fields with sewage sludge, which could, by extension, be used as a starting point for fate modelling. Beyond the case study specifically highlighted here, these metal laden particulate plastics are suitable to study fate, transport, eco-toxicity and interactions with organisms at trace concentrations.

117
Microplastics in urban stormwaters - designing a method to evaluate microplastic concentrations in stormwater run-offs
J. Talvitie, Finnish Environment Institute SYKE / Marine Research Center
Urban stormwaters have been suggested to act as a significant pathway for microplastics (MPs) to the aquatic environment. However, the actual data of MP concentrations in stormwater run-offs is scarce. In addition, there is no validated methods to sample, extract and analyse MPs from stormwaters. In this study, a flow-based high-volume sampling concept that gives event mean concentrations (EMCs) of MPs for sampled rain events was developed. The sampling concept is based on flow-based pumping and in-situ filtration. The samples are collected from the stormwater stream in the stormwater well. First, the V-dam is installed to the discharge side of the well. This makes the surface level of the stormwater stream in the well proportional to the flow rate of the stream. To determine the flow rate in real time (delay < 10 ms) the surface level is followed by using level transmitter. Programmable Logic Controller (PLC) collects and saves this information and uses it to control electrical pump with frequency converter. Pump is used for creating sample flow proportional to the stormwater flow. Also sample flow is saved to the PLC. This information is then stored to Cloud Server and can be accessed with PC either real time or later. PC programme and phone app is developed to follow and control the process. The sampling is performed repeatedly from one site with well known catchment area. As the quality of the stormwater is known to fluctuate due to several factors (e.g. land type and use, intensity and depth of rainfall, antecedent weather conditions), it is necessery to sample adequate amount of rain events to ensure reliable estimation of the total microplastic discharge. Enzymatic sample purification processes and automated FTIR analyses techniques will be applied with modifications for stormwater samples to gain high quality data.After the sample processing and analyses is performed, the EMC of MPs as particle account as well as in mass will be evaluated. After the sampling period (~ 6 months), the site mean concentration (SMC) of MPs will also be calculated for the catchment area.

118
Preparation of small microplastics and nanoplastics: challenges, technical gaps and environmental relevance
G. Balakrishnan Nair, Le Mans Université / IMMM Le Mans Université; M. Revel, Catholic University of the West; C. Mouneyrac, Catholic University of the West / UBL, Mer Molécules Santé; A. Huvet, Ifremer, LEMAR UMR 6539 CNRS/UBO/IRD/Ifremer; I. Paul-Pont, LEMAR UMR 6539 CNRS; P. Soudant, LEMAR UMR 6539 CNRS/UBO/IRD/Ifremer; f. lagarde, Institute of molecules and materials of Le Mans / Institute of Materials and Molecules of Le Mans IMMM UMR CNRS
Model particles of different sizes and nature of polymers are of great interest for improving knowledge on micro and nanoplastics impacts on organisms and helping their physical and chemical characterizations in aquatic samples. However, in the smallest size range (< 10 μm), particles of only a few types of polymers are currently available, especially commercially. For this reason, most toxicity tests were reported using PS micro and nanobeads whereas polyethylene (PE) and polypropylene (PP) fragments are by far the most common in the aquatic environments. In addition, commercial micro and nanobeads are usually stabilized using surfactants without knowledge of the additives formulation, which may modify their interaction pathway with aquatic organisms. So far, only a few studies reported protocols to prepare model micro and nanoplastics and some of them present cryomilling as an effective way to obtain reference microplastic particles. However, in these studies, the so-obtained particles are always in the range of several hundreds of μm and no study focused on the production of particles in the range < 100 μm or at the nano size with a standardised size range. In this work, we investigated the possibility to obtain consistent quantities of small particles of PE and PP by milling. The obtained results show that cryo-milling is a fast method to produce microplastics under powder form of all kinds of polymers with sizes > 50 μm. However, producing consistent quantities of particles < 50 μm or even smaller (nanoplastics) by this way remains challenging. We also present all the steps that are necessary to obtain the full characterization of produced particles. It shows that particles < 50 μm were produced but not easily extracted from the powders, a liquid extraction becoming necessary. It

underlines that after milling, the separation of particles in distinct size classes is also very challenging and the potential presence of particles smaller than expected has to be thoroughly checked. Overall, the necessity of a deep characterization in numbers and size of micro and nanoplastics produced by milling appears here primordial for impact assessment studies on biota. Finally, in this presentation, the environmental relevence of the particles produced by milling will be discussed regarding their composition, size, surface chemistry and stability in solution and species.

119
Identification and quantification of microplastic by Raman microspectroscopy
N.P. Ivleva, P.M. Anger, Technical University of Munich / Chemistry Department, Chair of Analytical and Water Chemistry; E. von der Esch, Technical University of Munich / Chemistry Department, Chair of Analytical Chemistry and Water Chemistry; C. Schwaferts, Technical University of Munich / Chemistry Departament, Chair of Analytical Chemistry and Water Chemistry; R. Niessner, Technische Universität München / Chemistry Department, Chair of Analytical and Water Chemistry; M. Elsner, Technical University of Munich / Chemistry Department, Chair of Analytical and Water Chemistry
The contamination of aquatic environment and food with microplastic (synthetic polymer particles in a size range of 1 μm – 5 mm) is of increasing scientific and public concern. However, the degree of contamination remains uncertain – e.g. the values for environmental samples range from less than one to more than million items per cubic meter. The contamination of environmental and food samples with smaller plastic particles (< 1 μm) remains unknown. To date, no appropriate analytical techniques for reliable analysis of submicro- (100 nm – 1 μm) and nanoplastic (< 100 nm) are available. While microplastic with sizes down to 1 μm can be both quantified and identified through morphological and chemical analysis by Raman microspectroscopy, the development of an automated analysis for smaller particles (down to the nano-range) is still outstanding. In this presentation, the feasibility of Raman microspectroscopy for the identification and quantification of (pigmented) microplastic as well as paint particles in environmental and food samples will be discussed. The focus will be on the optimization of the technique for automated analysis of plastic in the lower micro-, submicro- and nano-range, as these particles are of high interest due to their increased bioavailability and, hence, potential threat to aquatic organisms and humans.

Fate and Effects of Metals: Advances in Metals Risk Assessment and Regulatory Guidance (I)

121
Contribution of zinc from household and personal care products to wastewater
O.L. Tran, A. Peters, G. Merrington, wca; R. van Egmond, Unilever; J. Kilgallon, Unilever / Safety and Environmental Assurance Centre SEAC
Zinc is a naturally occurring essential element which is both required to some extent by all organisms, but is toxic if present in excess. It is ubiquitous in the environment and occurs at low concentrations in both drinking water and food, but is also introduced into the environment by anthropogenic activities. Zinc compounds are widely used in home and personal care (HPC) products, such as sunscreens, cosmetics and laundry detergents. These products often leave a household via the drain and end up in the wastewater system. However, there is an increasing academic and regulatory interest in 'down the drain' chemicals in HPC products contributing to environmental effects. Wastewater treatment may range from no wastewater treatment to sophisticated tertiary treatments capable of specific substance removal. Different treatment conditions can affect the fate and transformation of zinc in the effluent, where the speciation of zinc is a crucial determinant of the bioavailability and toxicity to aquatic and terrestrial organisms. This study considered the importance of different sources of zinc into the environment via municipal wastewater systems and the contribution from ambient backgrounds concentrations of zinc in environmental media. The results from a systematic literature review show that HPC products are likely to make a relatively limited contribution to overall loadings of zinc to sewage treatment plants, but a larger proportion of the total effluent zinc concentration in domestic wastewaters. Ambient background levels of zinc in foods result in significant quantities of zinc in faeces, accounting for 60 to 70% of the zinc loading in domestic wastewater and more than 20% of the zinc loading in mixed wastewater from domestic and industrial premises. Wastewater containing HPC products were estimated to make up approximately 15% of the domestic wastewater stream, thus these products are a relatively minor contributor to total zinc loadings in wastewaters. The output of this work may be useful in the environmental risk assessment of zinc for HPC products and may be used to inform regulatory strategies and priorities for zinc.

122
Mercury accumulation in Mediterranean lean fish
J. Grimalt, IDAEA-CSIC / Environmental Chemistry; E. Junqué, IDAEA-CSIC
Mercury is primarily associated with muscle tissue rather than with fat which, besides oily fish, points to predatory but non-migratory fish species, e.g. lean fish, for the accumulation of this metal. The present study is devoted to determine the concentrations of total mercury and methylmercury in a great variety of lean fish species from the Western Mediterranean Sea and to determine how consumption of these specimens contribute to the total mercury intake in human populations, and more specifically children. 607 commercial seafood samples from the Western Mediterranean Sea were collected (Feb 2014-Nov 2018). Samples from Egypt and the Atlantic Ocean (Senegal, Mauritania coasts) were also taken for comparison. Fish species were selected considering the most consumed by the population. The fish species were grouped in three trophic levels, those feeding on plankton (first), on small fish and crustaceans (second) and on fish and cephalopods (third). A considerable number of the analyzed fish species exceeded the maximum levels proposed by the European legislation, such as dusky grouper (100% of the examined specimens), common dentex (65%), conger (45%), common sole (38%), hake (26%) and angler (15%), among others. Representation of the Hg concentrations vs. weight of each specimen from the third trophic level showed a significant positive correlation, r = 0.78 ($p < 0.01$). The average THg intake due to fish consumption, 0.61 μg/g ww, involved Hg estimated weekly intakes (EWIs) of 5.7 μg/kg bw for children aged 7-12 years and 4.4 μg/kg bw for adults when referred to infant and general Spanish population. These values were higher than the provisional tolerable weekly intakes (PTWIs) for total Hg intake recommended by FAO/WHO, 4 μg/kg bw [4], 140% and 110%, respectively. In the worst case scenario, the children and adults were exposed to 47 μg/kg bw and 37 μg/kg bw, which exceded largely the established upper limit, 1200% and 930%, respectively. For MeHg, assuming that 90% of total Hg is in this form, the EWIs were 5.2 μg/kg bw and 4.0 μg/kg bw for the medium case and 42.5 μg/kg bw and 33 μg/kg bw for the worst scenario in children and adults, respectively. The PTWI for MeHg were set to 1.3 μg/kg bw which was lower than the EWIs for children and adults. Accordingly, the observed EWIs for children and adults were 400% and 310% of the PTWIs for MB and 3300% and 2600% for UB respectively. These values represented scenarios in which only local fish was consumed.

123
Black pine (Pinus nigra) bark as biomonitors of airborne mercury: sampling and analytical suggestions for minimising methodological biases
V. Rimondi, University of Florence / Earth Sciences; p. costagliola, University of Florence / Scienze della Terra; R. Benesperi, Università di Firenze / Dipartimento di Biologia; M. Benvenuti, Università di Firenze / Scienze della Terra; M. Beutel, University of California, Merced / Civil and Environmental Engineering; A. Buccianti, Università di Firenze / Scienze della Terra; L. Chiarantini, Università di Firenze / Centro di Microscopia Elettronica e Microanalisi (MEMA); P. Lattanzi, Istituto di Geoscienze e Georisorse-CNR; P. Parrini, Università di Firenze / Scienze della Terra
Tree barks are, in principle, excellent adsorbents of airborne pollutants, including toxic metals. Despite this, the use of tree barks for environmental monitoring was not widespread, although growing for air pollution biomonitoring studies. The skepticism of some researchers is based on: a) the need for a deeper knowledge into mechanisms of bark interaction with air pollutants, and b) limited data regarding variability in bark pollutants, both at a single site or between sites, which complicates the assessment of the actual environmental pressure on a given area. Concerning b), there is obviously a need for a commonly accepted sampling procedure to make the results more comparable and, hopefully, more reliable. The present study aims to outline some factors that may minimize sampling biases in the analysis of Hg in barks. In this work, barks of Black Pine *(Pinus nigra* J.F. Arnold) trees from the Abbadia San Salvatore district (Mt. Amiata region, Southern Tuscany, Italy) and the underlying soils were sampled in summer 2016. In this area two industrial activities, past Hg mining and ongoing geothermal energy production, affect local atmospheric Hg levels. For each site, we collected one sample of soil and eight bark specimens from a single tree. Barks were collected at two different heights, 70 and 150 cm, and in the four cardinal directions for each height. Total Hg in barks varies between 0.1 and 28.8 mg/kg dw. Almost systematically, the correlation between sample height and cardinal direction is better for samples picked up at a height of 150 cm with respect to those at 70 cm. A selected set of bark samples were subjected to a preliminary leaching test to evaluate the amount of Hg that could be removed by a rainy event. The results of the test show that the amount of Hg leached is negligible (maximum Hg concentration in the leach solution ~ 0.1 μg/L). For *Pinus nigra* species in the Mt. Amiata region, measured total Hg concentrations are independent of wind direction. To harmonize results on the employment of tree barks as a biomonitoring substratum, we suggest that a convenient sampling practice for Pinus nigra is to collect a 1-2 mm bark slice within the outermost 1.5 cm, at 150 cm from the ground even after a rainy event. Reanalysis of bark after two years showed a decrease in total Hg ranging from 5-20% of original values. While Hg

loss from bark sampels was not extreme, data suggests that barks should be analyzed soon after collection.

124
Effects of a sublethal metal mixture of 10%LC50 Cu, Zn and Cd on metal accumulation and ionoregulation in Cyprinus carpio
G. Castaldo, University of Antwerp / Biology; M. Pillet, University of Antwerp, Faculty of Sciences / Department of Biology (SPHERE Research Group); L. Bervoets, R. Blust, G. De Boeck, University of Antwerp / Department of Biology (SPHERE Research Group)
The aquatic environment is the final sink of waste streams and receives a huge number of different compounds including metals that can harm the health of aquatic organisms. Considering that we can not predict the toxicity of a mixture on the basis of single compounds, the analysis of mixture toxicity is needed to understand the impact of pollution in an aquatic ecosystem. Even if there are several studies describing the adverse effects of waterborne metals, it is more difficult to find information on the effects of trinomial mixtures. Therefore the main question of the present study is to assess if a mixture of copper, zinc and cadmium at 10% of their respective LC50 can be considered as safe. In order to answer this question, common carp were exposed to Cu: 4.8 μg/L; Cd: 2.9 μg/L and Zn: 206.8 μg/L at 20°C for a period of one week. We looked at fish survival rate and bioaccumulation, with additional physiological parameters to determine if there is an effect on ionoregulation and defensive mechanisms such as MT induction. Our results show a rapid increase in copper and cadmium concentration in gills and liver after one day of exposure. The accumulation of these metals showed adverse effect on ion-homeostasis; for example copper led to a sodium drop in the gills, liver and muscles. The decrease in sodium content affected the whole body ionoregulation, while a decrease in potassium levels was observed in in the liver. An increase in the gene expression for H^+-ATPase and a decreased expression of the Na^+-channel were observed after one day of exposure. We hypothesise that this increase in H^+-ATPase and the subsequent recovery of the Na-channel expression rates are an attempt to compensate for the reduced Na^+ uptake due to competition between copper and sodium at the uptake site. In addition a strong stimulation of metallothionein gene expression was reported during the whole experiment.

125
Evaluation of four first tier methods to measure metal(loid) bioaccessibility in polluted soils
P.A. PELFRENE, LGCgE-ISA, Yncréa Hauts-de-France; B. Le Bot, EHESP / LERES; C. Waterlot, LGCgE-ISA; P. Glorennec, EHESP; K. Sahmer, F. Douay, LGCgE-ISA
In the French context of polluted site management, the human health risk assessment is usually based on the total metal(loid) concentrations in the soil. Considering that the whole amount of a contaminant is available for organism after ingestion of soil particles, health risks are often overestimated. Moreover, this consideration opposes the concepts of bioavailability and bioaccessibility. To refine exposure and risk assessment, it is recommended to use bioaccessible concentrations of metal(loid)s. In France, the Unified Bioaccessibility Method (UBM) is considered as the oral bioaccessibility reference method. However, for French PSS (Polluted Sites and Soils) managers, this method appears as complex and time consuming, implies high technical skills and needs numerous chemical and biological reagents. Thus, a simplification to measure bioaccessibility of metal(loid)s might be of great interest. The objective of the present study is to propose a first tier method as a decision-making tool for managing polluted sites. The suitability of chemical extractions using acetic acid (0.11 M), citric acid (0.11 M), EDTA (0.16 M) and hydrochloric acid (0.65%) was evaluated to mimic the bioaccessible fraction of As, Cd and Pb in 209 soil samples including all major French soil types and a wide range of physicochemical parameters and metal(loid)s' concentrations. Statistical analyses (i.e. linear correlations) were established to determine the most relevant single-extraction method(s) capable of solubilizing As, Cd and Pb in the same concentration as those measured in both gastric and gastrointestinal phases defined by UBM. Significant relationships were obtained between As, Cd and Pb extracted in gastric and gastrointestinal phases and using the single-extraction methods. The results showed that the dilute hydrochloric acid test could be used as a suitable proxy to assess the gastric bioaccessibility of As, Cd and Pb in a first tier screening (ease-of-use, fast and reproducible method; reduction of analytical costs). Note that if these predicted bioaccessible values indicate that it may be worth to consider bioaccessility in terms of human exposure, then, in a second tier study, the UBM protocol may be used.

126
Assessment of metal(loid) bioavailability for landsnails and human bioaccessibility: a new pathway to build bridges between ecotoxicological and human health risk assessment of contaminated soils
m. louzon, Department of Chrono-Environnement, UMR UFC/CNRS 6249 University of Bourgogne Franche-Comté, 16 Route de Gray, 25000 Besançon; P.A. PELFRENE, LGCgE-ISA, Yncréa Hauts-de-France; B. Pauget, TESORA; F. Gimbert, University of Bourgogne Franche-Comté / UMR ChronoEnvironnement; N. Crini, University of FrancheComte / Department ChronoEnvironment UMR UFCCNRS; D. Rieffel, Department of Chrono-Environnement, UMR UFC/CNRS 6249 University of Bourgogne Franche-Comté, 16 Route de Gray, 25000 Besançon,; C. Amiot, University of Franche-Comte / Department Chrono-Environment - UMR 6249 UFC/CNRS; F. Douay, LGCgE-ISA; A. de Vaufleury, University of Franche-Comte / Department of Chrono-Environment
In the current context of polluted sites and soils, human health risk assessment (HHRA) and ecotoxicological risk assessment (ERA) are conducted independently and mainly based on the measurement of total contaminant concentrations in soils. Considering that all contaminants in the soil are mobile and available for organisms, these evaluations are in opposition with the bioavailability concept where only a fraction of the contaminant is assimilated by an organism and consequently cause adverse effects. To estimate more accurately the exposure of organisms to metal(loid)s, some tools exist for human such as oral bioaccessibility test or for the soil fauna such as bioavailability test for snails; however until now they have never been combined to look for possible bridges between HHRA and ERA. Thirty soils contaminated by arsenic, cadmium and lead were selected to cover a wide range of physico-chemical parameters and soil contamination levels. An *in vitro* chemical test of bioaccessibility mimicking the digestion of metallic elements (ME) (Unified Barge Method or UBM) and an *ex situ* biological test assessing the bioavailability of ME to snails were performed. The results of both methods were analyzed using simple and multiple linear regressions and were confronted to look for relationships between ERA and HHRA. For ERA, risk coefficients (RC) associated with bioavailability for snails were estimated based on accumulated contaminant concentrations and their inherent toxicity whereas for the HHRA, hazard quotients (QD) based on contaminant concentration in soils and weighted by the bioaccessibility results were calculated. Results showed an influence of soil parameters on ME bioaccumulation by the snail, *Cantareus aspersus* but not on the bioaccessibility, possibly due to the high acidic pH in the UBM test (compared to the neutral pH of the snail digestive tract) that can cause significant desorption of contaminants and limits the impact of soil parameters such as organic matter. Relationships established between bioaccumulation and bioaccessibility revealed adjusted R^2 between 0.73 and 0.94. In addition, correlations were highlighted by comparing RC and QD. For the three ME studied, a strong relationship exists between the ERA and HHRA methodologies. These results provide a basis for future ecotoxicological and human health risk assessment approaches of polluted sites and soils for organisms with various physiology and way of exposure.

Antimicrobial Resistance in the Environment

127
Contamination of antibiotic resistance genes in the Pearl River watershed and representative anthropogenic sources
L. He, South China Normal University; G. Ying, Y. Liu, South China Normal University / Environmental Research Institute
Antibiotic resistance is a global public health concern. China is the world's largest producer and consumer of antibiotics. A large number of antibiotics or antibiotic resistant bacteria/genes (ARGs/ARB) are discharged into rivers via domestic, hospital, and industrial wastewater. Urban rivers are considered as the sources and sinks of ARGs/ARB discharged by human activities. The distribution pattern, environmental pollution load and potential anthropogenic sources of antibiotics and ARGs in urban receiving water are needed to be explored. To investigate the impact of urban activities on the spread of antibiotic resistant, this study investigated the pollution characteristics of ARGs in the Guangzhou section of the Pearl River watershed. The removal rates of ARGs and antibiotics from typical anthropogenic sources by wastewater treatment facilities and the discharge load of ARG and antibiotics into the urban receiving waters were analyzed. Contamination of ARGs were determined by quantitative PCR. Concentrations of antibiotics were analysed for the collected samples following our previous method. Results showed that antibiotics and resistant genes were introduced into the receiving river directly or indirectly by representative anthropogenic sources via wastewater discharge. Landfills and livestock farms can effectively remove antibiotics and resistant genes. Municipal sewage treatment plants, pharmaceutical factories and hospitals should enhance their removal efficiency of antibiotic and ARGs from their wastewater. The total amount of antibiotics and ARGs discharged into the pearl river by the municipal sewage plant was 1,450 kg/year and 1.2E+21 copies/year, respectively. The pollution of ARGs and antibiotics in the Guangzhou section of the Pearl River watershed was closely related to urban anthropogenic activities. This may not only exacerbate the contamination of common environmental genes in waters, but introduce the undetected and clinically relevant ARGs into the urban receiving waters as well.This research has provided indispensable data on the distribution and dissemination of ARGs from various source in urban receiving waters and on the relationships between antibiotics and ARGs. These data will be helpful for risk assessment of ARGs and for government policy making. Future research is warranted to understand the mechanisms for the dissemination of ARGs/ARB in urban receiving waters.

128

Transport of antibiotic resistance exceeds their selection by residual antibiotics in wastewater-impacted rivers

P.C. Brown, Karlsruhe Institute of Technology (KIT) / Engler Bunte Institut Chair of Water Chemistry and Water Technology; E. Borowska, R. Peschke, Karlsruhe Institute of Technology KIT / Engler Bunte Institut Chair of Water Chemistry and Water Technology; T. Schwartz, Karlsruhe Institute of Technology KIT / Molecular Biology / Microbiology Department; H. Horn, Karlsruhe Institute of Technology KIT / Engler Bunte Institut Chair of Water Chemistry and Water Technology

Wastewater treatment plants (WWTPs) are point sources for both, the release of antibiotic resistance genes (ARGs) and the discharge of antibiotics (ABs) into the environment. While it is well established that ARGs emission leads to an ARGs increase in receiving rivers, the role of sub-inhibitory AB concentrations is also being discussed. However, the results obtained in this study suggest that, at environmental concentrations, ABs do not have an effect on resistance selection. Instead, we emphasize the significance of ARG transport and highlight the relevance of wastewater particles. In 10 L batch reactors, natural river sediments were exposed to a mix of ABs (5 μg/L) or wastewater particles (150 mg/L). Over a period of 2 months, in which ABs were continuously spiked at high concentrations (100 times above environmental concentrations), ARG abundances did not change in sediments. However, after addition of wastewater particles (one single spike), ARGs increased in bulk waters and in sediments by 1 to 5 log units. Interestingly, within 2 months, ARG abundances did not remain elevated but instead returned to their initial concentrations. We observed reduction rates of up to 10^{10} gene copies per litre per day in bulk waters within the first week after addition of particles. These losses can only partly explain the high ARG concentration shifts observed in sediments, hence, strong degradation processes must be involved. ARG concentration shifts in downstream environments are probably caused by a continuous import of ARGs from WWTPs. If this import is removed, concentrations are likely to decrease again.

129

A novel method for determining effect concentrations that select for antimicrobial resistance

A. Murray, I. Stanton, L. Zhang, University of Exeter; J. Snape, AstraZeneca UK Ltd. / AstraZeneca Global Environment; W. Gaze, University of Exeter / Medical School

Antimicrobial resistance is one of the most significant threats to modern society. Use, misuse and overuse of antibiotics clinically and in the community; in agriculture and in aquaculture results in antibiotics and antibiotic resistant bacteria being released into the natural environment. Environmental concentrations of antibiotics are very low (ng/L range), but recent studies have shown that these concentrations may be sufficient to select for antimicrobial resistance. Currently, environmental risk assessment of it terms of selection for antimicrobial resistance is not performed. This is because there is no ecotoxicological assay with selective endpoints (ie which determine concentrations of antibiotics that select for antimicrobial resistance). This work uses a previously published, qPCR method for determining effect concentrations of antibiotics in complex bacterial communities to validate a novel, rapid growth-based method developed in this study. Spatiotemporal inocula and culturing condition effects were also explored. Results show that standard ecotoxicological assays are not always protective against resistance selection, and selection for antimicrobial resistance could be occurring in particularly impacted environments. Predicted no effect concentrations (PNECs) derived using the qPCR and growth-based methods are highly comparable. Therefore the growth-based method is promising new tool to enable rapid environmental risk assessment to protect against selection for antimicrobial resistance.

130

Identifying Hotspots of Resistance Selection from Antibiotic Exposure in Urban Environments around the World

A. Boxall, University of York / Environment and Geography Department; J. Wilkinson, The University of York / Natural and Built Environments

To understand the impacts of antibiotics on resistance in the environment and the subsequent risks to human and animal populations, it is essential to understand the concentrations of these molecules in the environment. The levels of exposure and the types of antibiotics will vary significantly in different regions of the World due to differences in pharmaceutical availability, wastewater treatment connectivity and infrastructure, regulation and disease pressure. This study was therefore performed to understand the level of exposure for antibiotic compounds in urban aquatic environments around the globe in order to identify regions where environmental exposure to antibiotics could be contributing to the AMR problem. River water samples were obtained from 517 urban locations in 61 countries and then analysed for thirteen antibiotics using LC-MS-MS. Mean concentrations of antibiotics for each river system were compared to predicted no effect concentrations for resistance proposed in the literature to establish the level of risk. Data are now available for 31 of the countries with data for the other countries due by the end of 2018. Highest total antibiotic concentrations (3153 μg/l) were observed in Pakistan with seven of the thirteen compounds being detected. The most frequently detected compound was ciprofloxacin followed by trimethoprim and sulfamethoxazole. Concentrations of antibiotics in 19 of the 31 countries were below $PNEC_{Resistance}$ values indicating that environmental antibiotic exposure from rivers may not be a great contributor to the AMR problem in these countries. Rivers in Austria, Belgium, Cyprus, Iraq, Laos, Malaysia, Nigeria, Pakistan, Portugal, UK, USA had mean concentrations of at least one antibiotic above the $PNEC_{Resistance}$ indicating that resistance selection is possible in these regions. The compound of greatest concern was ciprofloxacin which was found to pose a potential risk in seven of the 31 countries studied so far. Our data analysis is ongoing to extend the range of countries investigated and to identify the environmental, technological and socio-economic drivers of exposure to these molecules as well as areas at risk within each river system.

131

The role of wildlife in the environmental dispersal of antimicrobial resistance in agricultural areas.

N. van den Brink, Wageningen University / Dept of Toxicology; A. Umanetc, Wageningen University / Department of Microbiology; F. de Boer, Wageningen University / Natural Resource Ecology and Management; P. van Hooft, Wageningen University / Dept Natural Resource Sciences; K. Matson, Wageningen University / Natural Resource Ecology and Management; J. Lahr, Wageningen Environmental Research / Team Animal Ecology; D. Mevius, Wageningen University Research Centre / Wageningen Bioveterinary Research; H. Smidt, Wageningen University / Laboratory of Microbiology

Antimicrobial pharmaceuticals are increasingly used in modern society, both for humans and animals. As a consequence, the prevalence of bacteria exhibiting resistance to these pharmaceuticals is increasing concomitantly, potentially having major impacts on the (future) effectiveness of antimicrobial products. A potentially major source of antimicrobial resistance (AMR) and antimicrobial resistance genes (ARGs) is related to agricultural practices. However, little is known about the environmental fate of ARGs, e.g., how they disperse, how long they persist, and what are the environmental reservoirs. In this presentation, we will provide details on the role of small wild mammals in the dispersal of ARGs in The Netherlands. Individuals of five species (white-toothed shrew (*Crocidura russula*), wood mouse (*Apodemus sylvaticus*), bank vole (*Myodes glareolus*), house mouse (*Mus musculus*) and common vole (*Microtus arvalis*)) were trapped at farms that differed in their usage of antimicrobial pharmaceuticals. Faecal samples collected from the trapped individuals were used to quantify the occurrence of ARGs. Different approaches were followed to identify differences in ARG prevalence among species and among farms with different agricultural practices. First, the species-specific microbial composition of faeces was established using Illumina sequencing of barcoded 16S rRNA gene fragments. Compared to the other species, white-toothed shrews had a clearly different microbiota composition. With the shrews excluded, Principal Component Analyses clearly ordinated the other species; bank vole and wood mouse were generally most different. Shrews had the highest diversity in their microbiota profiles; both vole species had the lowest. Differences between farms were less apparent. These results suggest that differences in the microbiota profiles in small mammals are related more to difference among species (e.g., diet preferences) and less to differences between sites. The occurrence of ARGs in the faeces was analysed with detailed shotgun metagenome sequencing of samples pooled per species and collection site. This pooling strategy was used to obtain enough starting material and was feasible because variation in microbiota profiles within species was much lower than between species. We will present details on the species specific diversity of ARGs in combination with gene maps and taxonomy ARG networks, all in relation to agricultural practice.

132

Development of a dose-response model for assessing risks from antibiotic resistant E. coli in agricultural water reuse

S. Chandrasekaran, S. Jiang, University of California, Irvine

Several recent studies have identified antibiotic resistant bacteria (ARB) and residual antibiotics in the effluent of wastewater treatment plants (WWTPs). This is especially true of WWTPs that accept effluent from hospitals or pharmaceutical manufacturers. Moreover, in addition to ARB discharged directly into the environment, the residual antibiotics in the effluent also exert a selection pressure and promote the buildup of additional ARB. This scenario is especially problematic when treated wastewater is used for agricultural irrigation in the effort towards water reuse. There is a potential for the development of infections that do not respond to antibiotic treatments. We here develop a dose-response model taking into account the fraction of antibiotic resistant *E. coli* in the treated wastewater in order to understand the magnitude of the threat. In this model, we assume that in the absence of antibiotics, the ARB does not possess increased virulence. This means that the same model used for the antibiotic sensitive bacteria applies for the resistant strain. However, in the presence of antibiotics, through co-ingestion of residual antibiotics and ARB with water or food, the ARB will survive and out compete the sensitive strains. Under such scenarios, the health outcome depends on three factors: the initial bacterial dose of ingestion, fraction of ARB and the concentration of antibiotic. The key contribution of this study is a dose-response model founded in stochastic growth kinetics that accounts for these three factors in determining the health outcome. We

demonstrate that the new model outperforms the existing dose-response model for *E. coli* infection in human trial studies. Predictions of human health outcomes are also made in the context of residual antibiotic quantities utilizing kinetic data from *in-vitro* experiments of the ARB to inform the dose-response model.

Alternative Approaches to Animal Testing for Ecotoxicity Assessments: Exploring New And Novel Approaches (II)

133

EpiSuite prediction models: suitable for natural toxins?

I. Rodríguez Leal, M. MacLeod, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

Screening-level assessment of natural toxins in drinking water in Europe is needed. Many potentially harmful toxins have been identified, but there is a lack of experimental measurements of their environmentally relevant partitioning properties (Bucheli. *Environ. Sci. Technol*., 2014). QSAR models can be used to estimate their partitioning, persistence and mobility in the aquatic environment, but the results should be interpreted carefully. Prediction of physico-chemical properties of interest are available as model outputs from QSAR models in EpiSuite. The training set of the models comprise a database of measured properties of anthropogenic organic pollutants. Natural toxins represent a completely different set of chemicals and hence, the applicability domain of the models is not established (Sahigara et al. *Mol. Basel Switz*., 2012). We extracted the training sets for the EpiSuite QSARs for biotransformation by fish (kM) and octanol/water partition coefficient (Log Kow) and calculated the Euclidean distance (ED) of chemicals from the centroid of the training set chemicals for chemicals in the training set and over 1500 natural toxins found in Europe. Even though the majority of the natural toxins lie within two times the average ED of the training set, comparison with recent experimental values of some of the toxins reveals an overestimation of Kow for polar molecules, among others. The lack of correlation would indicate that ED is rather a qualitative measure and cannot be used to assess the error range. Quantum chemical models, such as COSMO-RS, may be useful to bridge this discrepancy; they do not need a training set database because they are based on first principles (Klamt and Schüürmann. *J. Chem. Soc. Perkin Trans.*, 1993). Comparison with values obtained by other models are showed and discussed critically. Keywords: QSAR, natural toxins, applicability domain, COSMO-RS

134

Use of time-weighted average exposure values in the chronic aquatic risk assessment

M. Wang, WSC Scientific GmbH / Dept Efate Modelling; M. Hamer, Syngenta / Environmental Safety; A. Samel, FMC Corporation / Environmental Sciences; L. Weltje, BASF SE / Agricultural Solutions - Global Ecotoxicology; J.R. Wheeler, Shell International

In the risk assessment for aquatic organisms, by default the maximum exposure concentration is used. In the chronic aquatic risk assessment for Plant Protection Products (PPPs) in Europe, the time-weighted average (TWA) exposure may be used as refinement, when certain conditions are fullfilled. Indeed in some regions this is the default exposure expression. However, recently the application of TWA-based exposure values has been challenged in the EU, and instead the more conservative maximum exposure estimate is favoured. One concern is that effects may be driven by the magnitude of exposure over the short-term resulting in effects, which would not occur following equivalent TWA exposure at a lower level for a duration. For endpoints related to survival, this line of argumentation perhaps seems intuitively reasonable, that the absolute magnitude of exposure may be important in determining effects. However, the question arises whether or not this might also apply to other endpoints, such as growth and reproduction that typically more relevant to chronic risk assessment. Therefore, we explore the use of the TWA approach as an exposure refinement and whether it retains conservatism afforded at lower tier assesments. It was found that longer exposure at a lower level resulted generally in similar or greater effects than short but higher exposure. This was for endpoints relating to growth (frond number, fish length or weight) and production of offspring (no. of neonates/female *Daphnia*). Since for sub-lethal endpoints similar or higher effects were estimated at longer than at shorter exposure durations, it is expected that the use of TWA exposure estimates will be sufficiently conservative as an exposure measure in the aquatic chronic risk assessment.

Wilson, Sanofi U.S., Inc. / Health, Safety and Environment

Flexible, rapid, and predictive approaches that do not require the use of large numbers of vertebrate test animals are essential, as the chemical universe remains largely untested. Development of robust new approach methodologies (NAMs) and non-testing approaches requires the use of existing information via curated, integrated datasets. A large, diverse dataset was developed from a range of sources, with harmonization and characterization steps to ensure that the information could be effectively organized and mined. The resulting EnviroTox database (www.envirotoxdatabase.org) contains 91,217 aquatic toxicity records representing 1,563 species, and 4,016 unique chemical CAS#s. Chemical-specific information is linked to each record and includes physical chemical information, chemical descriptors, and mode of action classifications. Toxicity data is associated with the physical chemistry data, mode of action classifications, and curated taxonomic information for the organisms tested. The EnviroTox platform also includes three analysis tools: a predicted no effect concentration (PNEC) calculator, an eco-TTC distribution tool, and a chemical toxicity distribution (CTD) tool. This presentation will provide an overview of the EnviroTox Database and examples of how the database and its associated tools can be used to inform chemical evaluation and alternative method development. The first example demonstrates how the database and tools can be used in a water quality criteria and environmental quality standard application for organochlorine and acetylchlolinesterase pesticides. Records from the EnviroTox database were used to derive threshold values based on PNEC distributions for several pesticide classes (AChE inhibitors and organochlorines) and compared with existing regulatory criteria and discussed. Initial analysis of all records in the database classified as AChE inhibitors by ASTER (10,135 records for 176 chemicals) shows a $PNEC_{0.05}$ that generally agrees with several of the accepted regulatory criteria values. A second example explores how the NAMs can be effectively evaluated against existing acute and chronic data, using compounds classified as neurotoxic. In this case, 14,657 records on 263 substances classified as having neurotoxic modes of action (by ASTER) allows comparison of trophic level-sensitivity. In this case, invertebrates are 2 orders of magnitude more sensitive than fish and 4 orders of magnitude more sensitive than algae.

136

Predictive Weight of Evidence (pWoE) for Alternative Testing Systems

T. Aldenberg, RIVM; J. Ezendam, National Institute for Public Health and the Environment RIVM

The use of alternative (non-animal) tests as a proxy for the effect of chemicals on laboratory animals requires quantitative understanding of what individual test, or test combination, is sufficiently predictive for the toxicological endpoint at concern. In general, this problem is one of supervised statistical learning, supervised because we have a golden standard to quantify predictive success. Here, we are particularly interested in only a few tests, say 2 or 3, with a binary (two-valued) outcome, in combination with a binary response. The training sets involved are limited as well, in the order of 300 or so, often much less (100+). We have applied logistic regression to model the predictive strength and agreement of the alternative tests. However, instead of assessing overall goodness-of-fit, we have developed a predictive measure of Weight of Evidence (pWoE), which is proportional to the log odds, or log DLR (Diagnostic Likelihood Ratio), of the logistic regression. Here we take common logarithms, multiplied by 10 to obtain convenient and interpretable information units (known as *deciban*). A pWoE between +1 or –1 is considered as insignificant. Mathematically, pWoE equals the linear term in the logistic regression, corrected for the imbalance of positives and negatives in the response. Thus, we can estimate pWoE for each binary test combination, which is much more interesting than overall predictive fit. With the aid of bootstrapping, one estimates the uncertainty of pWoE values. Some test combinations then turn out to be more informative than others, and if test outcomes are in conflict, we can quantify the pWoE and its uncertainty of such combinations. For the case of three common tests for human patch skin sensitization, we show that two, or more, test-minuses always implies a response minus, but a complementary rule for plusses reveals a mixed response.

Development of a Bayesian network model for predicting fish acute toxicity from FET data: a probabilistic weight-of-evidence approach

A. Lillicrap, NIVA / Environmental Toxicology; S.E. Belanger, Procter & Gamble Company / Global Product Stewardship; K.A. Connors, Procter & Gamble Company / Environmental Stewardship and Sustainability Organization; J.M. Rawlings, The Procter & Gamble Company / Environmental Stewardship and Sustainability; R. Wolf, NIVA Norwegian Institute for Water Research; W.G.

Landis, Western Washington University / Institute of Environmental Toxicology; J. Moe, Norwegian Institute for Water Research (NIVA) / Section for Ecotoxicology and Risk Assessment
Reduction of animal testing, wherever possible, is required by legislations such as the EU Directive 2010/63/EU. Fish Embryo Toxicity (FET- OECD TG236) testing has been proposed to be an alternative to the juvenile acute fish toxicity test (AFT- OECD 203). However, FET data are not yet accepted as a replacement to the AFT test for certain regulatory purposes such as REACH. The European Chemicals Agency (ECHA) recommended that a weight-of-evidence (WoE) approach was needed for FET data before it could possibly be used in place of AFT data. Therefore, a Bayesian network (BN) model has been developed to incorporate multiple lines of evidence in combination with FET data in order to predict AFT. Bayesian networks are increasingly being used in ecological risk assessment because they can integrate large amounts of data and other information sources to produce discrete probability distributions, and predict the probability of specified states. The objectives of this study were: 1) To develop and evaluate a BN model for predicting toxicity of substances to juvenile fish from embryo toxicity data in combination with other relevant information; 2) To apply the BN model in a WoE approach which can support replacing juvenile fish toxicity testing with embryo toxicity testing. \n

Presenting the Plastic Leak Project: A pre-competitive initiative to harmonize plastic metrics
L. Iten, Quantis; A. Ernstoff, Quantis / Quantitative Sustainability Assessment; L. Peano, C. Dubois, M. Zgola, S. Humbert, Quantis; J. Boucher, Shaping Environmental Action & University of Applied Sciences and Arts Western Switzerland
Within the context of circular economy, plastic proves to be a promising material. However, in order for the material to achieve full circularity, leakages of both micro- and macroplastics have to be prevented. As the effects of plastic in the environment on human and environmental health have yet to be examined and for now remain unknown, the pressure to act quickly is high. A careful and robust quantification of the loss streams is needed to identify priority areas for meaningful actions. If this step is ignored, mitigation efforts could be focusing on minor leaks or worse, lead to unintended consequences on the environment. A major research gap has been identified as the projects conducted so far collectively lack of adequate leakage metrics, robust supporting methodologies and lack of a connection to life cycle thinking.\nQuantis, Environmental Action along-side stakeholders from both the public and private sector propose the Plastic Leak Project (PLP). The PLP will define methodological guidelines, deliver sector-specific default data and conduct case studies. The guidelines to quantify plastic leakage are suggested as a global reference on the topic, supported by recognized experts and top international organizations, many of which are already engaged as advisors and stakeholders. The delivered default data will be split in three categories: loss rates (e.g. tire abrasion), release rates (e.g. efficiency of waste water treatment plants) and activity data (plastic waste generation along the supply chain and country-specific end-of-life/recycling scenarios). The case studies will serve to test the guidelines and to leverage the work towards the identification of the hotspots of key area interventions to close the plastic tap. The assessment and prioritization of these actions will also be put in the a life cycle context and carbon footprint will also be assessed.\nThe PLP will add unique value as it connects the marine litter issue with existing environmental assessments. It thus provides a framework that allows for a holistic approach to the plastic leakages that allows to close the tap while avoiding the shift of environmental burdens. The PLP can thus be seen as the compass that leads to a circular plastics economy.

140
Exploring the accountability of marine litter generation at the life cycle inventory level
E. Sanye-Mengual, S. Nessi, S. Sala, R. Pant, European Commission - Joint Research Centre / Bioeconomy unit
Marine litter (or debris) is the "waste created by humans that has been discharged into the coastal or marine environment". Among marine litter, plastic marine litter is arising as an important environmental pressure and urgent policy matter due to its long durability and large presence (60-90% of marine litter). Some authors have estimated the global generation of macroplastics and microplastics as well as the potential impacts to the marine environment, biodiversity and human health. Resulting from the "Medellin Declaration on Marine Litter in Life Cycle Assessment and Management", the life cycle assessment (LCA) community is putting an effort on developing methods to address marine litter. Plastic marine litter encompasses macroplastics and microplastics (both primary and secondary), depending on litter size and origin. Macroplastics and microplastics can be emitted to the environment at any stage of the life cycle of a product due to direct or indirect actions, leading to an emission to the marine environment. This contribution aims at defining a framework to quantify the generation of macro- and microplastics at the life cycle inventory (LCI) level to set the basis for an indicator addressing marine litter in LCA. The proposed framework includes two indicators: Cumulative macroplastics generation (CMaG) (kg) and Cumulative microplastics generation (CMiG) (kg). CMaG can be estimated by applying product-specific marine litter rates (MRL) to the mass of each product in the LCI. Estimated MRLs are being calculated by product type and world region as the ratio between the amount of product littered (based on beach and marine counts) and the amount of product consumed. CMiG can be estimated by accounting for the primary and secondary microplastics generation along the life cycle of products. The main sources considered in this framework are plastic pellets (MiG_p), tyres (MiG_t), marine coatings (MiG_{mc}), road markings (MiG_{rm}) and synthetic textiles (MiG_{st}). Bottom-up estimations are based on literature and adapted to the LCI of products in relation to the mass of products and transported distance, mainly. Cosmetics and dust were excluded as primary microplastics sources. This contribution expects to (a) develop a framework to account for marine litter in LCA at the inventory level and (b) apply it to case studies of plastic products for its verification. The developed framework is also expected to be applied at a larger scale, e.g., EU-28 consumption.

141
Marine Impacts in LCA (MARILCA): a framework for marine litter life cycle impact assessment
J. Woods, NTNU The Norwegian University of Science and Technology; A. Boulay, CIRAIG - École Polytechnique de Montréal / Chemical engineering department; I. Vázquez-Rowe, Pontifical Catholic University of Peru / Civil Engineering Environmental Science; R. Geyer, University of California Santa Barbara / Bren School of Environmental Science and Management; F. Verones, NTNU / Department of Energy and Process Engineering
Environmental impact pathways from marine litter are not yet covered by life cycle impact assessment (LCIA) methods, potentially compromising the robustness of decision-support provided by LCA. For example, replacing all plastic bottles by glass would indeed reduce marine litter but increase other impact categories, such as global warming, and comparing these trade-offs is not possible if those impacts are not included and characterized. Filling this research gap is a high priority for the LCIA research community, as shown by the recent Medellín Declaration, which specifically calls for LCIA model development to account for potential damage caused by marine litter. Here, we present the output from Phase 1 of the MARILCA (Marine Impacts in LCA) working group process; a framework for developing LCIA models for, and illustrating the different impact pathways associated with, marine litter. The MARILCA working group operates under the UN Environment Life Cycle Initiative and with the Forum for Sustainability through Life Cycle Innovation (FSLCI) as a communication partner, the overall objectives of which are presented in a complementary poster presentation. A detailed mapping of possible impact pathways is provided, with guidance on the most important ones from an inventory perspective. Our developed framework links the generation of waste with potential damage to three areas of protection (AoP) namely ecosystem quality, human health and (the proposed AoP) natural heritage by describing mechanistic steps along impact pathways. We recommend development of material-, spatially- and size-differentiated LCIA models including details on fate, exposure and effect processes. Fate processes include those related to waste management (or mismanagement), transport in the environment, and material degradation. Together, the exposure and effect processes describe the potential consequences of marine litter on humans and ecosystems. The framework is centered on plastic litter impact pathways and is expandable to cover other materials constituting litter in the marine environment e.g. metals, glass, organic materials. Overall, we present the basis for harmonised LCIA model development that can first cover the predominant impact pathways and step-by-step generate a complete and coherent damage-level LCIA model for marine litter.

142
Development of characterization factors for the assessment of marine litter impacts in LCA
P. Saling, BASF SE / Sustainability Strategy; L. Gyuzeleva, University of Freiburg; K. Wittstock, V. Wessolowski, BASF SE; R. Griesshammer, University of Freiburg
Plastic pollution in our marine environment is taking place on a staggering scale with up to 12 million tonnes of new plastic waste entering the ocean each year. The main impacts of plastic debris on marine life are through entanglement or ingestion often having fatal consequences to individual organisms. Marine litter has been identified as one of the main drivers of biodiversity loss in marine environments, but there is still a high degree of uncertainty related to this issue. There is a growing body of research often focusing on the effects of plastics on individual marine organisms. Now that some of the effects and risks related to

marine debris have been identified, it is important that these impacts on the environment are measured in a systematic and quantitative way. Plastic debris impacts can successfully be implemented in life cycle assessment (LCA) and be measured along with other environmental impacts of products and processes. Today only a limited number of LCA impact categories are related to the marine environment and there is a general lack of focus on marine environments and particularly plastic debris. In the present study we assessed the impacts of certain selected polymers on the marine environment based on a comprehensive literature review and classified substances into different groups and impact categories. Based on these results we developed a characterization factor model for potential embedding into life cycle impact assessment models.

143
Plastic waste in water in Ecological scarcity 2103: Development of eco factor and its relevance in packaging LCA
T. Kägi, G. Roberts, F. Dinkel, Carbotech AG
Based on the publicly available data on the amount of plastic entering the water, an ecofactor for plastic emission, in water was determined for the Ecological Scarcity Method 2013 (Frischknecht & Büsser Knöpfel. After establishing the ecofactor, the second step was to determine the average proportion of plastic packaging or other plastic products that end up in the water based on substance flow data. With around 800 eco points (UBP) / g of plastic waste in water, the ecological factor is considerably higher than, for example, the ecological factor for CO2 (0.46 eco points / g CO2). The application to plastic products shows that taking this ecofactor into account leads to a significant increase in the environmental footprint of packaging. This is illustrated on the following example: If a packaging material (e.g. PET bottle) ist completely disposed of in water systems (worst case), the plastic waste in water contributes about a hundred times more to the environmental footprint than all other processes in the life cycle of the packaging material together. In average, we assume, based on Maier-Borst u. a., (2018) and Seyler u. a., (2016), that about 0.3% of a packaging material is disposed of in the environment. Regarding typical packaging materials this contributes about one forth to more than one third of the environmental footprint of a packaging material. (More results will be shown in the presentation). While the current flow and normalization flow is based on relatively reliable data, the critical flow is currently chosen arbitrarily. However, in the current political environment, we consider a 50% reduction to be a plausible target. The treshold value could be even stricter (which means a even higher eco factor). The introduction of the ecofactor for plastics into water leads to a substantial increase in the environmental footprint of plastic-based products, as soon as even a few per mille of them are disposed of into the water. This has a particularly relevant impact on the conclusions of studies comparing plastic products with other products to the detriment of plastic products. Many life cycle assessments about packaging materials are likely to arrive at different conclusions if this factor is taken into account.

144
When 'dissipative use' leads to an environmental impact: the case of space missions related impact on the orbital resource
T. Maury, University of Bordeaux / ISM-CyVi; P. Loubet, CyVi-ISM / ISM CyVi; A. Gallice, ArianeGoup / Design for Environment; G. Sonnemann, University of Bordeaux / The Life Cycle Group CyVi
Adopting a purely anthropocentric view, **the near-Earth orbits** where space activities take place can be encompassed as a part the '**Technosphere**'. In such case, orbits can be considered as an asset of natural resources supporting human activities. **Considering the whole life-cycle of a commercial space mission, the dissipation of the materials occurs in a systematic way after their use phase in orbit**. All the objects launch in space are dissipated in two way: or by staying 'out' of the natural environment once they are non-functional or with direct emissions in the atmosphere caused by the burning during the re-entry stage. In addition, a dissipation of mineral resources could be identifyed dealing with the combustion of the solid propellant during the ascending phase of the rocket. The resource dissipated within the orbital environment leads to a raising sustainability concern: 29,000 human-made objects larger than 10cm are orbiting the Earth but only 6% are operational spacecraft. Space debris is today a significant and constant danger for all space missions. **It is worth noting to note that the current orbital environment is the result of past and present *dissipative use* of the aerospace materials** spread mainly after the completion of the mission or after a collision with a debris. In the same way, the future state of the orbital environment will be directly linked to this dissipation phenomena regarding the contribution of each new mission scheduled. However, the impact linked to the *resource dissipation* is never taken into account in the current environmental LCA studies which adopt a *cradle-to-launch pad* approach. Therefore, a focus on the dissipated resource within the orbital environment seems today particularly relevant to ensure the sustainability of the outer space activities. Hence, our challenge is to integrate debris related impacts within the LCIA step to broaden the scope of LCA for space systems. First, we present a general framework to integrate the impact of the 'dissipative use' on the orbital resource. Then, we propose a set of Characterisation Factors (CFs) as a way of measuring the impact of the previous dissipated resource on the system under study. A case study will be presented to demonstrate the applicability of the methodology. The assessment of the potential trade-off occurring in term of environmental impacts on both the Earth and orbital environment will be discussed, comparing several Post-Mission Disposal (PMD) scenarios.

Difficult to Test Substances and Wastes: Regulatory Status, Testing Challenges, Interpretation of Data and Fulfilling Information Requirements

145
Environmental effects of data-poor metals: the example of palladium
J. Mertens, EPMF; M. Eliat, Arche consulting
The Platinum Group Metals ('PGMs') are poor in ecotoxicological data, inhibiting a proper assessment of the ecotoxic potential and risks. Driven by EU REACH, industry has been generating a basic dataset of acute aquatic toxicity data. For palladium, effects are observed at low μg Pd/L range. The test data also suggest varying toxic thresholds depending on the molecular structure of the Pd test compound. An extensive literature search was performed and all reliable data were combined in a datamatrix. The published literature only investigated the ecotoxic response of palladium chloride A testing program was established to generate ecotoxicity data for Pd compounds with variable coordination structure and for most critical test species, in order to compare test data for these Pd compounds and derive a robust set of ecotoxicity threshold values. Algae are identified as the most sensitive test species to Pd, with EC50 values as low as 3 μg Pd/L. However, algal EC50 values are up to 10+ times higher for different Pd compounds, and 100+ fold for fish. PGMs are known to have a strong coordination behaviour to (in)organic ligands in aquatic media. As such, and in contradiction to most data-rich metals, the presence of Pd as free Pd^{2+}-ion in solution is very low. By comparing the responses observed for various Pd compounds, it will be checked if toxicity differs between coordination complexes, and if there is a general predictor of toxicity. One of the tools that will be used is the QICAR (Quantitative Ion Character-Activity Relationships) model that is under development and will be available at the end of 2018. Taking into account all the above, an appropriate approach will be defined to derive environmental toxicity threshold values. The learnings from this work will be applied in a next step to other PGMs like Platinum, Rhodium and Ruthenium.

146
Interpretation of algal growth rate data for aquatic classification of rapidly degrading substances; Zinc pyrithione as a case study.
K. Clark, Lonza AG / Product Safety and Toxicology; S.E. Belanger, Procter & Gamble Company / Global Product Stewardship
Algal growth rate inhibition at 72 hours, expressed as 72h ErC50s and ErC10s, is the preferred algal endpoint for aquatic classification according to the CLP regulation (1272/2008) and OECD 201 is the preferred test guideline. However, the CLP regulation and OECD 201 are neither well adapted to rapidly degrading substances nor address the diversity of taxa useful in assessments. The use of 72h ErCx values based on mean measured concentrations of rapidly degrading substances can significantly overestimate toxicity. Characterizing acute toxicity of rapidly degrading substances with a 72h ErC50 can also be inconsistent with the definition and concept of acute toxicity in the CLP regulation, which is an effect during a short term exposure relative to lifecycle. The use of shorter study durations could be a solution for rapidly degrading substances, but the first validity criterion in OECD 201 relates to biomass increase and may not be fulfilled in less than 72h, particularly for slower growing taxa than those described in OECD 201. These points are illustrated with data from a recent study conducted with zinc pyrithione (ZPT) in the marine diatom, *Skeletonema costatum*. ZPT is photolytically unstable and rapidly degraded in algal toxicity studies due to required lighting conditions. Concentrations dropped rapidly to less than 50% of initial concentrations by 24h, then continued to decline to about 10% of initial by 72h. The 72h ErC50 based on mean measured concentrations from this study is less than an initial concentration that caused no discernible growth rate inhibition at any time point. *S. costatum* growth in the controls was constant, consistent and exponential but not reaching 16x increase before 72h. Therefore, according to the guideline, shorter study durations were not considered valid. Similarly, OECD 201 does not allow for use of nominal concentrations in this case. The conclusion that the 72h ErC50 is the most relevant for classification in this situation, despite being lower than an initial concentration showing no effects, is neither reasonable nor consistent with the principle of acute aquatic toxicity. For rapidly degrading substances, a better approach to assessing acute and chronic algal inhibition (toxicity) is needed. Options could include use of nominal concentrations for toxicity estimates, use of recovery tests to assess algicidal concentrations, shorter test durations and specific considerations of the taxa under evaluation.

147
Determining bioconcentration factors of constituents of essential oils using in-vivo benchmarked dietary exposure studies
R. Samson, Stockholm University, ACES; C.L. Chen, South China Normal

University / Environmental Research Institute; M. McLachlan, Stockholm University / Environmental Science and Analytical Chemistry (ACES); G. Horlitz, Stockholm University, ACES / ACES; M. MacLeod, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

Persistence (P), potential for bioaccumulation (B) and toxicity (T) are established criteria for the (regulatory) assessment of chemicals. While PBT testing methods are standardised for single component chemicals, there is a lack of standard methods for the assessment of complex mixtures. An example are essential oils - fragrance materials that are registered as natural complex substances (NCS) under the European REACH legislation. NCS are widely used, but their potential environmental hazard is not fully understood. Models predict that many essential oils are likely toxic for aquatic wildlife and persistent. They are also suspected to be bioaccumulative, but the available predictions for "B" are scarce and only "moderately reliable" (ECHA website). A challenge for determining the bioconcentration factor (BCF) of essential oils is that it cannot be readily measured using a standard flow-through experiment. The OECD 305 guideline provides the option to determine the BCF using a measured depuration constant (kT) from dietary exposure and an estimated uptake rate (k1). However, this approach has been criticised for the variable quality of k1 estimates based on the used models - and hence potential limited reliability of the resulting BCFs. To assure the quality of BCFs from dietary exposure, we used well-characterised reference chemicals (chlorobenzenes (DiCB, TrCB, PeCB), PCB3, PCB52 and musk xylene) for which the determined BCF were compared with literature data. Using our previously reported benchmarking methodology, we determined the BCF of key components in cedarwood and pine oil as well as the reference chemicals in a single dietary exposure experiment on rainbow trout. Using hexachlorobenzene (HCB) as benchmark, the BCFs for the main components of pine oil, cedarwood oil, and the reference chemicals were between 500 L kg^{-1} (Bornyl Acetate) - 55200 L kg^{-1} (PCB52). The apparent BCF value for HCB was 2244 L kg^{-1}. The determined BCF of the reference chemicals were within the same order of magnitude of reported literature values and resulted in the same assessments regarding "B". Using benchmarking, we established a robust method for the measurement of kTs of NCS in fish with a single dietary exposure, as well as establish a quality control for the resulting BCFs.

148

Biochemical biomarkers opposite effects - characteristics, meaning and methods for proofing

B.K. Hackenberger, D.K. Hackenberger, Department f Biology, University of Osijek / Department of Biology; . Lonńarī, Department of Biology, University of Osijek / Department of Biology

Biochemical biomarkers are widely used as sensitive and early warning signals of exposure to different kind of pollutants. Some biomarkers or their combinations are an indicator for the presence of a specific pollutant or group of contaminants in the environment. Biomonitoring procedures are usually based on the comparison of measured values of biomarkers in field or exposed organisms with control/intact organisms or benchmarks. The most common interpretation of biomonitoring using biochemical biomarkers consists of simple rules based on the decrease/increase of some enzyme activity or presence/absence of some chemical compound in test organism. Due to such expectations, the events of the opposite effects are largely neglected. Within this report, the data contained in recent literature, as well as the results of our experiments, are compared and presented. In addition to the usual type of opposite effect (hormetic like effect), there are some evidence of the existence of so-called double or two-way hormetic like effect. A significant number of scientific papers with opposite biochemical biomarker effect measured was found. However, only in a few papers (less than 1%) such results were also described in the text. The results of our experiments showed that the occurrence of opposite effect is not rare, only in some cases difficult to prove, mainly as a consequence of an insufficient sample size that would allow detection of subtle changes in biomarkers. If, at the highest dose of effectors (that inhibit some system element), organisms are still vital, it is possible to expect an onset of additional mechanisms able to compensate the inhibited system element resulting with a specific response curves. On this curve it is possible to recognize four asymptotes or levels: normal, hormetic, minimal and compensatory level. The most common opposite effects are hormetic like effects, while recently double or both-sides hormetic effects are described and proven. The better knowledge of low-dose toxicology, as well as a knowledge of phenomena that differ from the generally accepted dose-response models are very important because opposite effects can also be harmful to organisms. Moreover, the techniques and methods that could detect and prove the effect in low-dose range could be used as tools for the detection of early toxic effects. This is particularly important for the biomonitoring of environmental pollution and for an environmental risk assessment.

149

Evaluation challenge of waste toxicity at oil extraction

E. Kovaleva, M.V. Lomonosov Moscow State University / Department of Soil Science; M. Guchok, ANO Ecoterra; S. Ledovskikh, Ecoterra Autonomous Non-Commercial Organization; P. Korolev, Moscow State University / Department of Soil Science; V. Terekhova, Lomonosov Moscow State University / Lab of Ecotoxicological Soil Analysis

Increasing oil extraction activity all over the world, imperfect technologies of oil production leads to formation of different wastes, containing petroleum hydrocarbons. Drilling cuttings are one of the oil extraction wastes, consisting of solid rock material and residuals of drilling fluid. Drilling cuttings could be landfill or utilize to recultivants. Being contact with environmental components, drilling cuttings or their composites, could impact the environment and remain toxic effect for many years. Ecotoxicological tests in combination with chemical studies could be the most suitable approach to assess the ecotoxicity of oily wastes and prevent contamination risk. We studied the ecotoxicity of drilling cuttings and the composites, formed on the base of drilling cuttings, in order to find the safety admixture and their ratio to return a waste in transformed state into environment. Five different admixtures and the wastes were tested. Drilling cuttings were mixed with sand to improve physical characteristics, peat and kieselguhr (diatomaceous earth) to increase the sorption capacity, phosphogypsum to regulate the acid medium of the mixture and cement to give mechanical robustness. We applied the bioassay to assess the toxicity of drilling cuttings and the formed composites. We evaluated the initial concentration of contaminants in aqueous extracts from wastes and compositions that may immobilize 50% of crustaceans and infusorians, but available approaches of bioassay have significant restrictions for implementation. The tested samples contained high level of water soluble salts (up to 50 g kg^{-1}).The eluate and direct phytotoxicity tests were run, using seeds of mustard (*Sinapis alba* L.) and oat (*Avena sativa* L.). The drilling cutting samples with TPH content higher than 3.0 g kg^{-1} were toxic, then how the composite variants with TPH content less than 35 g kg^{-1} stimulated the plant growth compared with the control. Treatment with kieselguhr and peat allowed sorbing TPH and tracing metals, that approved a positive effect of chosen ingredients and their ratio. The water filtrates characterized by neutral pH (7.4), TPH content between 1.5-3.1 mg L^{-1}. We conclude it is the shortage of appropriate approaches for ecotoxicity assessment of wastes and obtain the solid results. It is highly demanded to work out new methods to evaluate the toxicity of specific waste based on their composition, properties, aggregation and natural conditions of zone they formed.

UVCB substances: Methodology for substance identification and an endpoint non-specific selection of computationally generated representative constituents

S.S. Kutsarova, UniversityProf. Dr. Asen Zlatarov / Laboratory of Mathematical Chemistry; D. Yordanova, University of Zlatarov / Laboratory of Mathematical Chemistry; M. Comber, Mike Comber Consulting; C. Hughes, Ricardo Energy & Environment / Chemical Risk; E. Vaiopoulou, European Petroleum Refiners Association; S.D. Dimitrov, University of Zlatarov / Laboratory of Mathematical Chemistry; O. Mekenyan, Prof. Asen Zlatarov University / Laboratory of Mathematical Chemistry

Keywords: UVCBs, representative sample, hazard assessment, *in silico*

Substances of unknown or variable composition, complex reaction products and biological materials (UVCBs) comprise about 40 % of all registered substances submitted to the European Chemicals Agency. One of the main characteristics of UVCBs is that they have no unique representation. They are usually described by generic substance identifiers such as names of chemical classes, structural formulas, reaction steps, physicochemical properties, or spectral data. Defining an inambigious structural description aims to complete the following two tasks: to allow performing of *in silico* hazard assesment, where structutal information is essential, and to contribute towards fulfilling the requirements of implementaion of any chemical related legislation. It has been acknowledged that one of the obstacles for the explicit structural description of the UVCBs is the large number of possible structural isomers. A methodology, based on the generic substance identifiers, is developed to address this issue. The methodology allows for the coding of constituents, their generation, calculation of important characteristics of UVCB constituents, and selection of representative constituents. Two main formats are developed: Generic Simplified Molecular-Input Line-Entry System (G SMILES) and Generic Graph (G GRAPH). G SMILES is a SMILES-based single line notation coding fixed and variable structural features of UVCBs. G GRAPH allows generation of constituents coded in G SMILES, calculation of physicochemical properties, simulation of reactions, selection of constituents and their storage in a text file. There are two main types of selection of constituents. The first one is an end-point driven selection based on ranges of a characteristic physicochemical property, e.g. log*Kow* values are critical when assessing bioaccumulation potential. The second approach is a statistical selection of the minimum number of generated constituents representing a UVCB. This representative sample is selected in such a way that the structural variability and the properties of concern of the UVCB are approximated within a predifined tolerable error. The aim of the statistical selection is to enable the assessment of UVCB substances by decreasing the number of constituents that need to be evaluated. The procedure, which is shown to be endpoint independent, was validated theoretically and on real case studies.

Your Science or my Science? When the Sides taken on a Research Topic are Impacted by Different Philosophical Positions and Values (II)

151
Food contact chemicals and human health: facts and fiction
J. Muncke, Food Packaging Forum Foundation / General Management
Chemicals migrate from all types of food contact articles (FCAs). Which chemicals migrate and at what levels depends on physico-chemical parameters of both the FCA and the foodstuff. Over ten thousand chemicals are intentionally used in the manufacture of FCAs, and many more are present in finished FCAs as non-intentionally added substances (NIAS). EU regulations require a risk assessment for each migrating chemical. But for many of the intentionally added substances (IAS) toxicological data are insufficient, lacking or dated. Many of the NIAS are unknown which means it is not possible to assess their hazard, exposure and risk using conventional risk assessment approaches. Indeed, several food contact chemicals are endocrine disrupters but their hazard characterization is not routinely performed. And many chemicals migrate simultaneously from a finished FCA, indicating the need for mixtures risk assessment which is currently not required. Therefore, novel methods are being used, including computational tools, in vitro bioassays and in vivo approaches. And an enhanced hazard characterization would address today's most prevalent chronic diseases in the human population, by targeting human health outcomes of concern.

152
Food Contact Materials – wishes and reality
T. Gude, Swiss Quality Testing Services
Food contact materials and especially their safety assessment are more and more of higher interest. This depends on one hand on the changing views to chemicals in light of the REACH registration and the hereby-linked re-assessment of safety aspects. On the other hands, it depends on the usage of such materials like in food contact materials in terms of environmental aspects combined with a very restrictive view on toxicology and its real impact. Currently every month a new substance – so far widely used in food contact applications – is in the focus and linked to potential toxic effects. This creates a lot of rumour in the value chain, especially in the retailer channel and finally for us, the consumer. Within this, new publications related to toxic effects, it always is forgotten, that materials like food contact materials do have a positive impact on food safety and food waste management. A change of a very effective system cannot be done very shortly, as a longer development phase is needed. Nevertheless, if compounds with proven toxic profile are used they need to be replaced. However this must be based not only on potential toxic effects mainly shown in higher concentrations, it is mandatory that concentrations migrating from materials in light of a relevant exposure showing such toxic effects. Currently it can be observed that the classification of chemicals is mainly based on effects, not on concentration. This procedure leads to a high pressure on companies to replace proven effective food contact material systems by unproven new systems – possibly associated with new problems. A little more patience and a more pragmatic approach might be helpful to deal with food contact materials. One aspect of a pragmatic approach is not only focussing on individual compounds, but also considering full food contact material solutions.

153
Risk assessment of food packaging materials: use of data and methodologies in the scientific assessment
C. Roncancio Pena, EFSA / Food Ingredients & Packaging
In accordance with Regulation (EC) No. 1935/2004 on materials and articles intended to come into food, the EFSA's Panel on Food Contact Materials, Enzymes and Processing Aids (CEP Panel) evaluates the safety of certain substances prior to their authorisation for use in Food Contact Materials (FCM) plastics. EFSA provides scientific advice to risk managers, by communicating on risks to the public and by cooperating with Member States and other parties to deliver a coherent, trusted food safety system in the EU. EFSA should remain a forward-looking organisation that possesses the tools to address new and complex risks. Within this perspective and in order to establish the safety from substances migrating from FCM, both toxicological data indicating the potential hazard and the likely human exposure data need to be combined. In case of testing from migration using food stimulants, the use of mathematical migration models has developed significantly in recent years. EFSA is also actively identifying and collecting information regarding new testing strategies that could be applied to the different sectors of EFSA's work, including the use of the weight of evidence approach, evaluation of mixtures and its genotoxicity, publishing guidance documents, to transparently communicate the principles guiding the risk assessment and at the same time supporting the applicants/interested parties when preparing a dossier to be submitted for evaluation.

Schwenk, University of Koblenz-Landau / Institute for Environmental Sciences
The role of freshwater ecosystems as a source of nutrients, energy and pollutants is a relatively underappreciated research field, compared with the impact of catchment properties on receiving surface waters. Pollutants may reach the terrestrial ecosystems, and thus lead there to an exposure, through a biological pathway, i.e. via emerging insects or aquatic prey consumed by terrestrial predators. Alternatively, an abiotic pathway exists, and aqueous-phase or particle-bound pollutants are transported via flood events to the surrounding terrestrial habitats. Once pollutants reach the terrestrial ecosystem, they may lead to top-down or bottom-up directed effect cascades in the terrestrial ecosystem/food web, yet our knowledge on the effects in the terrestrial recipient system is extremely restricted. In this context, stable isotope analysis is a valuable tool to untangle the complexity of interactions in the receiving ecosystem supporting an informed decision making as part of chemical risk assessment or ecosystem management. This presentation will summarize the state of the art in the field of cross-ecosystems effects of chemical pollution at the aquatic-terrestrial interface.

Subcellular metal partitioning in benthic organisms to estimate the proportion of metal trophically available to wild fish
N. Urien, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; H. Sonnenberg, EcoReg Solutions Inc; L.D. Ramilo, Ecological and Regulatory Solutions Inc. / Environmental Services; P. Campbell, Université du Québec / INRS Eau Terre Environnement; P. Couture, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement
In aquatic environments, metals may pose a risk to benthos and to the fish feeding on them. Previously, it has been shown that subcellular metal partitioning in prey can influence metal availability for trophic transfer. It is generally understood that metals found in organelles and cytosol of prey represent trophically available metals (TAM) to predators, whereas metals associated with the NaOH-resistant granules and cellular debris fractions pass through the gut for direct excretion. The aim of this study was to assess trophically available metals (TAM) in white sucker (*Castotomus commersonii*) prey for As, Cd, Cu, Se and Zn, using a subcellular partitioning approach. For that, invertebrates from different functional feeding groups (*Hyalella azteca*(HA): shredder; *Hexagenia*(HE): gatherer; and *Enallagma*(EN): predator) were collected in a lake located downstream from a metal mining discharge (~40% effluent) and in a reference lake. Subcellular partitioning among "organelles and cytosol" (TAM fraction), "granules" and "debris" was determined after differential centrifugation, NaOH digestion and heat-treatment steps. The amount of metal associated with each fraction was

determined by inductively coupled plasma mass spectrometry. For all metal(loid)s studied, total concentrations were significantly higher in exposed compared to reference invertebrates, with the exception of As, Cd, Cu and Zn in EN, for which no statistical differences were found. Selenium accumulated the most in all organisms (from 15 to 40-fold), followed by Cd (from 5 to 8-fold). The [Cd] in the detoxified granule fraction was higher in exposed HA and HE compared to those observed in reference organisms, whereas [Cd] in the other fractions remained low and constistent between areas. Contribution from the granules in exposed HA and HE was dominant (> 80%) and contribution from the TAM was very low (< 14%).Hence, trophic transfer of Cd via consumption of those invertebrates is notlikely to occur. In contrast, [Se] were systematically higher in the "debris" and "organelles and cytosol". Proportions of Se were similar in reference and exposed organisms for the three subcellular fractions. Contribution from the TAM fraction was about 30% for HA, 40% for EN, and 55% for HE. Given that [Se] were markedly higher in the exposed compared to reference invertebrates, trophic transfer of Se via consumption of these invertebrates is likely to occur, and represents a risk of toxicity for fish.

158

Implications of trophic variability on modelling bioaccumulation of persistent organic pollutants in marine Arctic ecosystems

R. Hoondert, Radboud University Nijmegen / Department of Environmental Science; N. van den Brink, Wageningen University / Dept of Toxicology; M. Van den Heuvel-Greve, Wageningen IMARES / Marine Coastal Systems; A.M. Ragas, Radboud University / Department of Environmental Science; J.A. Hendriks, Radboud University Nijmegen / Department of Environmental Science

The occurrence of persistent organic pollutants (POPs) in the Arctic has been of constant concern, as they are known to cause adverse effects in organisms at higher trophic levels, including mortality. Despite the banning of many of these compounds, high levels of POPs have been reported in Arctic biota, likely due to a combination of unfavorable chemical properties and northward marine currents. As the Arctic acts as a chemical sink, this system makes an interesting case for bioaccumulation studies, hence the growing interest in this topic. Typically, bioaccumulation of chemicals is evaluated by calculating trophic magnification factors, based on sampled chemical concentrations, requiring an extensive amount of empirical research. Consequently, multiple *in silico* mechanistic methods have been developed to predict bioaccumulation of hazardous compounds in food chains, which have been predominately validated for temperate food chains, due to lack of sampling of biota in Arctic areas and the strong seasonality of trophodynamics in Arctic systems, mainly driven by fluctuations in light and temperature, affecting the community composition and therefore prey availability. The aim of the present study was to obtain a better understanding of how bioaccumulation models perform when subjected to high trophic variability in Arctic ecosystems. Data were collected on trophic positions (TPs) of Arctic species, based on stable nitrogen isotopic values, by an extensive literature search, together with data on POP concentrations and species- and chemical-specific parameters. Bioaccumulation of POPs in the present study was calculated using the OMEGA bioaccumulation model. In each Monte Carlo iteration, trophic levels were re-binned based on the earlier derived TP probability distributions. Bioaccumulation could be modelled for three areas (Canadian Beaufort Sea, Canadian Archipelago and the Svalbard Archipelago), encompassing a total of 60 compounds. Highest efficiencies/lowest RMSEs were calculated for PBDEs, PFASs and PCBs, while the model performed less well for PAHs. Although in the majority of cases, bioaccumulation was slightly underestimated, variability in trophic position of a species showed to have only minor implications for bioaccumulation modelling.

159

Contaminated sediments effect on aquatic insects - cross boundary transport of nutrient and contamination

J. Lidman, Department of biology and environmental science, Umeå university / Department of Ecology and Environmental Science; . Berglund, Umea University / Ecology and Environmental Science; M. Jonsson, Umea University / Department of Ecology and Environmental Science

Anthropogenic contamination of aquatic environment can affect insectivorous birds both directly through exposure to contaminants transported by aquatic insects and indirectly by changing the food availability. In this study we used nine lakes with different concentrations of lead (Pb) to assess the effect of Pb on aquatic insect community composition and production and analyzed metal concentration within emerging aquatic insects to estimate the metal flux from the aquatic environment. A comparison between metal concentration in insect larvae and adults was also done to study the effects of metamorphosis on metal exposure risks. Community composition changed with increased Pb exposure but was only observed in the benthic community with proportionally more Trichopterans and less Ephemeroptera when Pb increases. A surprising positive correlation between Pb concentration and Ephemeroptera and Trichoptera abundance was observed which indicates that other factors are influencing the insect community. Metal flux from the aquatic to the terrestrial system by aquatic insects ranged between 65.9â_110.8 μg/m2 during the study period. Metal concentration differed both between insect orders and between adults and larvae within the same insect order, with higher Pb concentrations in larvae and predatory insects. A higher concentration in larvae shows that metamorphosis influence the exposure risk for terrestrial insectivores feeding on aquatic insects. The results clearly show that contaminants in aquatic systems can affect both food availability and exposure risk for terrestrial organisms.

160

Agriculture and mining contamination contribute to a productivity gradient driving cross-ecosystem associations between stream insects and riparian arachnids

F.J. Burdon, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment

Stream and riparian ecosystems can be strongly connected via the emergence of aquatic insects, which form an important prey subsidy for a wide range of terrestrial consumers. However, human perturbations that impact coupled ecosystems may propagate across habitat boundaries. Here, I explicitly investigated how stream pollution states influence communities of stream and riparian invertebrates in 37 forested stream types. Previous research has suggested that donor-habitat productivity gradients influence resource flows, and I hypothesised that stream pollution states would strongly contribute to a resource continuum driving cross-habitat connectivity and community composition. Streams receiving acid mine drainage (AMD) supported low levels of benthic insect and riparian arachnid biomass, whereas streams in forest fragments surrounded by agricultural land-uses seemingly were more productive, with greater standing crops of stream and riparian invertebrates than AMD or reference sites. Structural equation modelling confirmed the positive influence of standing benthic insect biomass on riparian arachnids. Human impacts seemingly also increased the concordance between invertebrate assemblages, suggesting that resource flows may affect community structures across habitats. Overall, these findings highlight how human activities (e.g., mining, agriculture) that influence stream pollution states may weaken or strengthen aquatic-terrestrial linkages.

Socio-Economic Analysis in Chemicals Regulation and Policy Making: Current Challenges and the Way Forward

161

SEA under REACH: State-of-play and areas for improvement

C. Rheinberger, ECHA / Risk Management Implementation Unit

Socio-economic analysis (SEA) under REACH has matured over the last 5 years or so and several practices have been improved and aligned with economic theory. In this presentation, we will present an overview of the current state-of-play of SEA conducted to support applications for authorisation and restriction proposals. We will draw on experiences from more than 200 uses applied for authorisation and about 30 restriction cases to highlight problems, discuss proposed solutions, and identify areas for further improvements.

162

Incentives for truthful reporting in seeking authorisation for using substances of very high concern

D. Slunge, gothenburg university

In order to attain an authorisation for the use of a substance of very high concern (SVHC) within REACH, companies need to prove that the benefits of use are larger than the costs. Due to asymmetric information, it is difficult for the regulator to know if the information about costs and benefits for continued use of SVHCs provided by the companies is correct. Based on a review of the estimated costs and benefits in 114 socio-economic analyses submitted to ECHA we examine if there is evidence of untruthful reporting by companies seeking authorisation. Furthermore, we discuss design options for an authorisation system providing effective incentives for truthful reporting of costs and benefits. One option is an 'SVHC use fee', being a share of the SVHC substitution costs reported by companies seeking authorisation.

163

Political Economy of Inclusion on the REACH Candidate List of Substances of Very High Concern

J. Coria, University of Gothenburg / School of Business Economics and Law

The European Union regulation on the registration, evaluation, authorization, and restriction of chemicals - known as REACH- is intended to improve the protection of human health and the environment through the better and earlier identification of the intrinsic properties of the thousands of chemicals commonly used in the EU. Both the European Chemical Agency and member states can prepare dossiers proposing substances to be considered for inclusion on the Candidate List of Substances of Very High Concern. The registry of Intention (ROI) is a public registry intended to make all interested parties aware of the substances for which a dossier is intended to be submitted. The Registry of Intentions is divided into three separate sections including current intentions, submitted dossiers and withdrawn intentions and submissions. In this study we investigate what types of SVHC are suggested by different countries, and in particular, how the national production of the substances and their toxicological properties can affect the countries' decision

to submit a dossier. Moreover, we investigate what substances for which a dossier has been submitted are finally put forward for inclusion on the Candidate List

164
Can SEA be a reliable decision-making tool for proper risk management on chemicals in a safe and circular economy? The metals industry perspective
H. Waeterschoot, Eurometaux
SEA considerations may help in both ex-ante as ex-post evaluations of risk management measures (RMM) and in assessing the optimality of such measures under REACH or CLP. On REACH, SEAs build on risk-based information and the suitability (or not) of alternatives to define the cost effectiveness of different RMMs. SEAs often need to overcome the lack of comprehensive data by using defaults and sensitivity assessments to cover for uncertainties. When communicating the outcome of SEAs for decision-making on the further use of or constrains on chemicals, the challenge is the often-different perspective of stakeholders on effectiveness assessments of RMMs. Examples from the metals sector will show how SEAs on chemicals management can combine different perspectives and help in effective decision-making to reduce risks during the substance's life-stages. Closing the materials loop by recycling and reuse is for metals and inorganics a critical economic and environmental step toward sustainability but can be a challenge too. SEA and Analysis of Alternatives therefore require a wider scope than the manufacturing and use stages. Examples including case studies will show how such broader frame could be established and help scientists and regulators identify need, scope and format of an RMM.

165
Impact assessment in SEA: A structured review of 24 REACH registration dossiers
I. Hilber, Agroscope ART / Environmental Analytics
A core component of SEA used in REACH authorisation and restriction processes is impact assessment. In our study we evaluate twenty-four REACH restriction dossiers regarding the methodological setup of the impact assessment. Furthermore, we examine how the outcomes of impact assessment influence the evaluation of one or several risk management options (RMOs) for restricting the substance, and the selection of the most preferred option. In addition, we investigate whether or not the selection of the preferred RMO is objective, transparent, and comprehensible. Our results show that a comparison of impacts focuses on selected impacts only (in particular human health and economic impacts). While this can sometimes be explained by the very specific scope of a restriction dossier and by lacking data, we also observe a lack of approaches for assessing environmental, health, social, and distributional impacts from chemicals use, and we formulate suggestions how this can be overcome.

166
SEA experiences from RIVM (The Netherlands)
A. de Blaeij, J.K. Verhoeven, National Institute for Public Health and the Environment RIVM
The presentation elaborates on our experiences and lessons learned with Socio Economic Analyses (SEA) for hazardous substances under REACH and in other regulatory contexts. During the previous years, the RIVM, in its role as a competent authority under REACH and as research institute, has worked extensively in the field of regulatory toxicology and risk management of hazardous substances. SEA can be useful for a variety of risk management issues around substances of concern, both linked to ecotoxicity as human health, and in various stages in the risk management process. Various research projects have been conducted within the framework of strengthening the SEA methodology, such as guidance for the performance of an Environmental Impact Assessment (EIA), Health Impact Assessment (HIA) and risk governance in SEA. In this presentation, we will e.g. discuss the importance of problem definition, scenario definition and scoping in the SEA process and investigate what socio-economic elements can be considered within SEA in the context of chemical legislation.

Criteria and Methods for Identifying Chemicals of Greatest Concern

168
The Origin and Evolution of Assessment Criteria for PBT Chemicals and POPs
M. Matthies, University of Osnabrueck / Institute of Environmental Research; K.R. Solomon, University of Guelph / School of Environmental Sciences; M. Vighi, IMDEA Water Institute / Earth and Environmental Sciences; A. Gilman, Sustainable Solutions International; J. Tarazona, European Food Safety Authority / Pesticides Unit
Public concern over the effects of persistent chemicals began in the early 1960s. Since then, significant scientific advances have increased our understanding of persistent, bioacumulative, and toxic (PBT) chemicals and the properties and processes that influence their fates in, and adverse effects on, humans and the environment. In addition to the scientific advances, a number of legal instruments and agreements for global, international, and national identification and control of persistent organic pollutants (POP) and PBT chemicals have been adopted. However, some of the rationales and thoughts that were relied upon when the first criteria were developed to identify and categorize PBT chemicals and POPs have not been carried forward. Criteria for identification of PBT chemicals and POPs have been based upon available data for neutral hydrophobic "reference chemicals", derived under laboratory conditions, and consensus-based policy decisions. Criteria have evolved over the last decades due to the diversification of the protection aims under various national regulatory frameworks and international agreements, advances in methods for estimation of physical/chemical properties, and the identification of chemicals which are non-traditional POPs. Criteria are not defined purely by science; they also are subject to the aims of policy. This paper offers a historical perspective on the development of criteria for PBT chemicals and POPs. It also offers suggestions for rationalization of protection goals, describes some emerging procedures for identification of compounds of concern, and proposes information that needs to be considered when applying criteria to screening and/or evaluation of new chemicals. The genesis of this presentation stemmed from a perceived lack of a full understanding in the scientific and regulatory community of the original intentions and scientific methods available to identify PBT chemicals and POPs. The understanding of the historical background of the definition of PBT and POP criteria and its modification due to the aims of policy is of increasing interest for the chemical risk assessment community. Matthies M, Solomon K, Vighi M, Gilman A, Tarazona J. The Origin and Evolution of Assessment Criteria for Persistent, Bioaccumulative and Toxic (PBT) Chemicals and Persistent Organic Pollutants. Environ Sci:: Processes Impacts 2016,18, 1114-1128.

169
The use of PBT assessment criteria in regulatory environmental risk evaluations: Challenges and Opportunities using cyclic volatile methylsiloxanes (cVMS) as a case study
K. Thomas, Global Silicone Council
There is a broad recognition that a risk-based weight-of-evidence (WoE) approach should be used in the context of a PBT assessment to evaluate the risk of chemicals, and that single criterion should not be used to make definitive PBT determinations. Regulatory evaluations in Europe, Canada, and Australia have assessed the environmental risk associated with cyclic volatile methylsiloxane (cVMS) compounds. These regulatory risk evaluations provide an opportunity to highlight key differences in the approaches used to assess the compounds, and to understand the implications of those differences for the outcomes of the evaluations.

170
Identification of chemicals of potential concern based on structural similarity
P. Wassenaar, National Institute for Public Health and the Environment (RIVM); E. Rorije, N. Janssen, National Institute for Public Health and the Environment RIVM; W. Peijnenburg, RIVM / Center for Safety of Substances and Products; M.G. Vijver, CML Leiden University / Environmental Biology
There is a strong demand for more attention and improved grip on chemicals of potential concern to address societal discussion on unwanted emissions of potentially hazardous chemicals. This is acknowledged by the European Commission (setting out a long-term vision of a non-toxic environment) as well as by the Dutch Ministry of Infrastructure and Water Management (setting out the ambition to identify so-called "potential-Substances of Very High Concern"). To this end, we developed a methodology that allows identification of chemicals of potential concern based on structural similarity with substances of known concern. The approach uses the similar property principle, which states that structurally similar chemicals are likely to have similar properties. The methodology focusses on substances with Carcinogenic, Mutagenic or Reprotoxic properties (CMR), Persistent, Bioaccumulative and Toxic or very Persistent and very Bioaccumulative properties (PBT/vPvB), or Endocrine Disrupting properties (ED). We analysed the predictive performance of 112 different similarity measures, consisting of a binary fingerprint and a similarity coefficient, for identification of chemicals of potential CMR, PBT/vPvB or ED concern. A dataset of 554 substances with known concerns for CMR, PBT/vPvB or ED properties was used. In addition, 412 control substances that were known to lack CMR, PBT/vPvB and ED properties, were selected. The best combination of fingerprint and similarity coefficient showed a high predictive performance with a balanced accuracy of 0.82 for CMR, 0.95 for PBT/vPvB and 0.99 for ED. This methodology will be implemented in a software tool that can be used to assess whether a new or existing substance, for which no toxicity data is available, is of potential concern based on structural similarity with chemicals of known concern. The methodology is specifically developed as a first screening tool, and can for instance be applied by emission licensing authorities, who are often confronted with the need to permit emissions for chemicals with limited or even no toxicity information available. When a chemical is considered to be of potential concern

based on structural similarity, a more in-depth analysis should be considered. Furthermore, the developed approach can help in selecting and prioritizing substances for follow-up within regulatory frameworks and thereby contributes to enhanced grip on chemicals of potential concern.

171
Application of the RAIDAR Model to Aid Chemical Prioritization in Canada
J.A. Arnot, ARC Arnot Research & Consulting / Adjunct Professor, Department of Physical & Environmental Science/Department of Pharmacology and Toxicology; J.M. Armitage, AES Armitage Environmental Sciences, Inc / Physical and Environmental Sciences; L. Toose, Liisa Toose Environmental Research; M.A. Bonnell, Environment and Climate Change Canada / Ecological Assessment Division
The traditional approach method (TAM) for chemical assessments is to categorize chemicals using various "bright-line" pass/fail criteria for Persistence, Bioaccumulation and Toxicity (PBT). However, new approach methods (NAMs) to screen and prioritize chemicals based on estimates of exposure and potential risk have recently emerged, an example of which is the Risk Assessment IDentification And Ranking (RAIDAR) modeling framework. RAIDAR combines chemical fate and transport at a regional scale with bioaccumulation in aquatic, terrestrial and agricultural food webs using toxicokinetic models thereby providing the opportunity for holistic exposure- and risk-based high-throughput and screening-level assessments. Here we conduct a case study to compare RAIDAR exposure- and risk-based metrics to PBT classifications for approximately 10,000 organic chemicals. Chemical property and toxicity data were compiled from various sources whereas emissions estimates were obtained primarily from estimated production volumes. Simulated exposures to a range of ecological receptors were quantitatively compared to toxicity data and expressed as chemical-specific Risk Assessment Factors (RAFs). The RAFs calculated for the 10,000 chemicals span approximately 18 orders of magnitude thus providing a single and relatively simple means for prioritizing the chemicals based on potential risks to a range of ecological receptors (i.e., aquatic and terrestrial species). Chemicals classified in this example as "PBT" and "not PBT" show an overlap of approximately 12 orders of magnitude when compared based on RAFs. In other words, many chemicals classified as "no concern" using PBT methods have risk estimates comparable to chemicals classified as "PBTs". This comparison indicates the potential for "false negatives" when considering PBT classifications and the potential for adverse effects to the environment. Conversely, many chemicals classified in this case example as ""PBT" have lower RAFs than many of the "non PBT" chemicals indicating the potential for "false positives" when seeking to identify chemicals with potential for adverse effects to the environment. The results also suggest that significant effort and resources can be spent prioritizing, testing and assessing chemicals that present a lower concern in the environment (i.e., are likely not true chemicals of concern), primarily due to a wide margin of exposure.

172
Early identification of both chemical and microbial contaminants in the aquatic environment using scientific literature text mining
J. Hartmann, Dutch National Institute for Public Health and the Environment / Centre for Sustainability, Environment and Health; I. van Driezum, National Institute for Public Health and the Environment RIVM / Centre for Sustainability, Environment and Health (DMG); S. Wuijts, National Institute for Public Health and the Environment RIVM / Centre for Sustainability, Environment and Health; B. Venhuis, National Institute for Public Health and the Environment RIVM / Centre for Health Protection; A. de Roda Husman, National Institute for Public Health and the Environment RIVM / Centre for Zoonoses and Environmental Microbiology; J. van der Hoek, Delft University of Technology / Water Management
Contaminants in the aquatic environment pose a potential threat to ecosystems and to humans. Humans may be exposed to contaminants in water resources when used for drinking water production and recreation. Climatological, social and demographic changes as well as the increasing sensitivity of analytical techniques result in the augmented detection of contaminants. Thus, effective risk governance of contaminants in the aquatic environment is and will remain very important in order to protect human and environmental health. Recent research has shown that it generally takes about 15 years from the first onset of concern about a contaminant to the peak of concern and thus regulatory action or mitigation. The first onset of concern is often a scientific article. We hypothesize that one of the factors influencing the period of emergence of concern about contaminants is the fact that the first article about the contaminant is lost in the vast amount of publications. It is not until more articles are published about the specific contaminant that the signal is picked up by regulators. In this study, we therefore propose a methodology using text mining for identifying the first signal of the detection of a contaminant in the aquatic environment. The proposed methodology uses scientific literature text mining, which is the automatedtextual analysis of the combination of title and abstract. The methodology is R-based and consists of five steps: 1) a search in Scopus, 2) adding abstracts to the retrieved records using R, 3) pattern matching in R to semi-automate the primary study selection, 4) finish the primary study selection manually, and 5) check the national relevance of the identified signals. The search query used was a combination of four concepts that each included several synonyms. The four concepts of microbiological and chemical contaminants were *contaminant*, *detection*, *new*, and *aquatic environment*. The proposed methodology enables regulators to proactively assess relevant signals of emerging contaminants in the aquatic environment based on automated literature research. Next steps involve developing a targeted monitoring program to analyse water samples for the identified signals relevant for the environment and population in the Netherlands.

Micro(Nano)plastic Pollution: Tackling the Plastic Problem by Identifying Sources, Investigating Fate and Novel Approaches (IV)

174
Simplifying Microplastics
M. Kooi, Wageningen University & Research / Aquatic Ecology and Water Quality Management Group; A. Koelmans, Wageningen University / Aquatic Ecology and Water Quality Management
Microplastics are perceived as complex. They include particles that are highly diverse in size, shape and density. Additionally, they consist of mixtures of polymers and chemical additives, and when exposed in the natural environment, absorption of chemical contaminants and the formation of biofilms further enhances their complexity. Many studies now struggle with the complex challenge that microplastics pose, and focus on small subsets of the microplastic matrix. Instead of focussing on the complexity and diversity of microplastics, we need to conceptually simplify microplastics. Microplastics can be seen as one entity, with a parameter space of probability distributions. A parameter space provides all combinations of values for all different plastic parameters, or properties, included in a study. Often, the individual properties are approximated using probability distributions, which describe how likely it is that a certain property values will occur. These probability distributions capture the diversity of the different properties, which for microplastics could include size, shape, density, colour, chemical composition, biofilm and attachment efficiency. For instance, microplastic particles vary in size between 100 nm and 5 mm according to most definitions. However, the majority of studies find that smaller particles are more abundant than large particles. Therefore, the particle size could be approximated using a for example a power-law probability distribution which results in a rapid decrease in particle number with increasing size. As another example, microplastic densities are often assigned discrete values for different polymers. However, in reality these densities overlap and form a more continuous distribution. Particles often contain mixtures of polymers, and once in the natural environment, biofouling, swelling and weathering could change the density of the particle. Using probability distributions to describe microplastic properties and studying the parameter space of these properties will greatly enhance our understanding of the complex microplastic matrix. The approach can be applied to exposure measurements, fate modelling, effect studies and ultimately risk assessments. When studying the risk that microplastics pose, instead of providing a yes/no answer for small subsets of microplastics, we could provide a probabilistic risk assessment for microplastic as a whole.

175
PET Microplastic of Textile Origin - Size distribution, characterization and retention in a lab-scale Wastewater Treatment Plant
M. Lykaki, Technische Universitat Dresden / Department of Evironmental Sciences; Y. Zhang, Dresden University of Technology / UFT Centre for Environmental Research and Sustainable Technology Department Sustainable Chemistry; M. Markiewicz, Technische Universitaet Dresden; S. Stolte, Technische Universitat Dresden
Microplastics (MPs), particles < 5mm, are nowadays subject of intense interest and research due to the enormous annual release of plastics into ecosystems and their potential threat to human health. Among plastic debris, polyester fibers originated from synthetic textile shedding have been considered as an important source of contaminants. Over 40 million tons of polyester fibers alone are produced per year entering the environment through wastewater effluent. It has been estimated that a typical wash load of 5 kg polyester fabrics could release from 7×10^5 up to more than 6×10^6 microplastic fibers. The aim of this study is to understand the occurrence and fate of polyester fibers in dependency of their length. Therefore, fluorescent-labeled polyethylene terephthalate (PET) textiles have been washed in a household washing machine and the effluent passed through a filtration cascade including filters with mesh sizes between 1500 and 5 µm. Separated fibers were characterized through visual analysis with fluorescence microscopy and image analysis software. The different PET size fractions have further been investigated towards their retention in mechanical, chemical and

biological stages of Wastewater Treatment Plant (WWTP) on lab-scale. First results on the quantification of fluorescence-marked PET fibres from washed polyester textiles demonstrate that the highest release of MP was recorded for two size fractions, 500-150 µm and 150-50 µm (fractions smaller than 5 µm were not quantified). Laboratory tests simulating WWTP processes suggest that MP fibres could be efficiently removed (>80%) from complex matrices such as activated sludge. Furthermore, it was demonstrated the use of flocculants such as $Al_2(SO_4)_3$ facilitated the aggregation and precipitation of fibres. This is the first study focusing exclusively on the performance of polyethylene terephthalate (PET) fibers, one of the most common materials used in the apparel industry and demonstrating that the behavior of textile-origin microplastics in wastewater treatments may be size and density dependent. The results could provide a better understanding on the impact of MPs in the environment and suggesting innovative techniques for possible future monitoring purposes.

176

Nanoplastic in a porous media: improbable transportation or realistic deposition?

A. Pradel, Université de Rennes 1; J. Gigault, University of Rennes 1 / Laboratoire Geosciences

Nanoplastics (NPs), defined as colloids that originate from the unintentional degradation of plastic, have recently been detected in the North Atlantic Ocean. As a colloid in aqueous systems, NPs present a continuum in sizes ranging from 1nm to 1μm, associated to asymmetrical shapes and Brownian motion [1]. These particles could pose specific ecological and health risks. In the life-cycle of a plastic debris, the terrestrial compartment is the main source and water is the main vector. So it appears crucial to describe NP transport in soils. Up to now, the large majority of published results concerning the ecotoxicological impact and environmental behavior of NPs used engineered plastic nanomaterials (polystyrene latex spheres) whose properties are significantly different from those of NPs (ie: monodisperse and spherical) [1]. In this study, we tackle such approach by describing the fate of different types of nano-sized plastics in a porous media, in conditions that are unfavorable to attachment (ie: repulsion). Size standard polystyrene (PS-std) latex spheres and an environmentally-relevant NP model (PS-m) were used. The parameters discriminating each of these particles are their average hydrodynamic diameters (200 to 500nm), surface properties (presence or absence of carboxylate functional groups) and shape (spherical or asymmetrical), mimicking more or less closely NPs. Their transport and deposition was evaluated using colloid filtration theory, DLVO theory and hydrodynamic modeling. Our results show that PS-m are more likely to be trapped in the porous media compared to the standards used in "nanoplastics" environmental investigation (PS-std). PS-m also undergo changes in size, unlike PS-std. The presence of geochemical heterogeneities in the porous media may increase adsorption of PS-m and carboxylated PS-std. Deposition was mostly reversible, suggesting that the particles may be remobilized. This study suggests to reconsider the existing data on the environmental behavior of NPs in porous media since engineered plastic nanomaterials have limited to no environmental relevance. 1. Gigault J, Halle A ter, Baudrimont M, et al (2018) Current opinion: What is a nanoplastic? Environ Pollut 235:1030–1034. https://doi.org/10.1016/j.envpol.2018.01.024

Occurrence of microplastics in commercial table salts and its implication to environmental fate and human exposure

S. Kim, J. Kim, H. Lee, Incheon National University / Department of Marine Science; H. Kim, Greenpeace East Asia

Salt intake is of particular concern to human exposure to microplastics (MPs). Previous studies which have identified MPs in commercial table salts including sea salt, rock salt, lake salt, and well salt showed a large variaiton in abundance (0 – 40,000 MPs/kg) and different composition profiles of MPs. Significant differences among studies in MP analysis methods makes it difficult to compare their results directly, to address the origin of MPs in salts, or to estimate human exposure. A reliable picture about geogrpahical distributio of MP pollution in global scale is available just when harmonized and consistetn method is applied. Recently, we determined the abundance and distribution characteristics of MPs in 39 table salt brands which are sold in supermakerts of 17 countries, including 28 sea salts from 16 countries, 9 rock salts from 8 countries, and 2 lake salts from two countries. FTIR analysis confirmed that MPs in each salt was not associated with its packing material. In entire salt samples, MP particles were detected with a range of 0 – 13,629 MPs/kg: 675±2560 MPs/kg in sea salt, 38±55 MPs/kg in rock salts, and 245±307 MPs/kg in lake salts. The distributions of polymers, shapes, and colors of MPs varied among salt types. MPs

Co-gasification of microplastics and biomass: syngas quality index

A.I. Ramos, INEGI / INEGI; A.I. Rouboa, University of Pennsylvania / Mechanic Engineering and Applied Mechanics

Microplastics have been considered one of the most concerning environmental issues as reported in recent reviews [1-3]. They originate from plastic products which are utilized and disposed of on a daily basis, supporting bioaccumulation effects that reach higher levels in the trophic chain [4-6]. Gasification embodies an interesting disposal option for plastic waste streams, granting not only environmental advantages but also the achievement of syngas, a commercial gas composed of CO, CO_2, H_2 and light hydrocarbons which might be utilized to produce marketable assets [7]. These include electricity, chemical products and even hydrogen or similar fuels for the transport sector [8, 9], which could even be used as an alternative to replace fossil fuels [10]. Gasification of plastics has been studied for the last decades as an attempt to substitute current waste processing techniques by more sustainable options, simultaneously contributing to this bolder aim [11, 12]. Several studies report the gasification of plastic debris as a possible technique to reduce their presence on the environment [13-16], some even suggesting the conversion of microplastics [17, 18]. Actually, gasification might portray some difficulties, i.e. problems in the feeding step and the formation of contaminants if plastic materials are treated alone. Yet, these may be attenuated if biomass is used as co-fuel [13, 15, 19]. This work aimed to evaluate the syngas produced from the gasification of different mixtures of PET (polyethylene terephthalate) microplastics and biomass, namely its quality and possible utilizations. This was attained through numerical runs with the software ASPEN Plus, which enabled the optimization of the experimental conditions. This strategy supports the dual benefit of Waste-to-Energy techniques, reducing the amount of plastics in the environment as well as sustainably generating commodity assets that currently rely on fossil fuels. Therefore, mixtures of microplastics and biomass within a range of 0% PET to 90% PET were assessed and some quality indicators were calculated. Higher CO and H_2 yields were seen for higher PET fractions, which enabled dedicated end-use applications for the achieved syngas.

Are "bioplastics" a safe alternative to conventional plastics? In vitro toxicity of extracts from plastic products

L. Zimmermann, Goethe University Frankfurt am Main; C. Völker, ISOE - Institute for Social-Ecological Research / Water infrastructure and risk analyses; M. Wagner, Norwegian University of Science and Technology NTNU / Bioanalytical Toxicology Group

It is well established that chemicals intentionally or non-intentionally present in plastics, that is, plastic additives and side products, migrate from consumer products, thus representing a source of exposure to wildlife and humans. Previous studies have demonstrated that chemicals in plastic food contact materials (FCMs) induce toxicity *in vitro* and *in vivo*. Bio-based and biodegradable plastics are considered as a sustainable alternative for their petroleum-based counterparts. However, data is missing whether they also represent a safer alternative regarding their chemicals' toxicity. Thus, our study aims at comparing the toxicological and chemical profiles of a range of everyday FCMs and their precursors made of bio-based and/or biodegradable polymers. We extracted 44 products currently available on the German market made of polyethylene (Bio-PE) and polyethylene terephthalate (Bio-PET) derived from renewable resources, polybutylene adipate terephthalate (PBAT) and polybutylene succinate (PBS) derived from fossil fuels as well as polylactic acid (PLA), polyhydroxyalkanoates (PHA), cellulose, bamboo- and starch-blends, which are both biobased and biodegradable. We analysed the *in vitro* toxicity regarding unspecific (baseline toxicity, oxidative stress response) and endocrine endpoints (estrogenicitiy and antiandrogenicity). We characterise the chemical composition by non-target high resolution mass spectrometry (LC and GC-QTOF-MS). Out of the 26 products analysed so far, all contained chemicals triggering baseline toxicity. Here, we observed the highest toxicity for cellulose-based products. While seven extracts activated an oxidative stress response and five inhibited the androgen receptor, no sample contained chemicals activating the estrogen receptor. Overall, at least one product of each material induced at least one endpoint in addition to baseline toxicity. Exceptions are the PHA and bamboo-based products for which we have analysed one product only. Our findings indicate that extracts of bio-based and biodegradable plastic products can induce a range of toxicological endpoints and are not necessarily a less toxic alternative to petrol-based materials. The ongoing chemical analysis will reveal their chemical composition and clarify whether the "bio-materials" contain the same substances as conventional plastics.

Fate and Effects of Metals: Advances in Metals Risk Assessment and Regulatory Guidance (II)

Kaija, Geological Survey of

Finland
Arsenic is a toxic and carcinogenic semi-metal. Greater than average As concentrations may occur naturally in bedrock and soil, but major risks in agricultural soil are linked with pollution. European geochemical mapping programmes have revealed that in central and southern Europe, As concentrations are higher on average than in northern Europe. In 2017, we started the AgriAs project to investigate the speciation and transformation of As in soil, its uptake by plants and impact on vegetation. The goal has been to evaluate the risks through agriculture and provide tools for risk management. Recommendations have been compiled in close cooperation with authorities and stakeholders. Our study sites, Verdun in France and Freiberg in Germany, exhibit As contamination in agricultural soils. Over one billion shells and projectiles were fired in Europe during World War I. After the war, over three Mt of abandoned and unexploded ammunition had to be destroyed in northeast France for safety reasons, among them a huge amount of As-bearing chemical agents. At many destruction sites, topsoil contamination is still severe. The results of the AgriAs sampling campaign in Verdun showed As concentrations from 15 mg/kg in the reference zone to 775 mg/kg in a more contaminated location. Arsenic is phytoavailable and toxic to plants. After 800 years of mining in the Ore Mountain region in Saxony (Germany), 288 km^2 of agricultural soils showvalues exceeding the German action value of 50 mg/kg As. The centre of historical mining in Freiberg mainly shows concentrations above 320 mg/kg. Alluvial soils in the floodplains along rivers in this region have As concentrations from 80 to 320 mg/kg due to drainage water from mining tunnels and discharged process water and sediments from ore processing. Risk and recommendations have been communicated by the German authorities for As-rich soils used for agriculture and gardening as well as residential areas. The AgriAs project will develop more general recommendations for the risk management of arsenic in European agroecosystems. These recommendations will include an overview of sources and pathways of As and a summary of European legislation with national guideline values. Recommendations will be developed for site characterization, risk assessment and risk management including good agricultural practices and water management. Recommendations for further research and policy development will be finally summarized.

181
Copper toxicity to fish in natural Amazonian water: The influence of dissolved organic matter
A. Cremazy, University of British Columbia / Department of Biological Sciences; C.M. Wood, University of British Columbia / Zoology; S. Braz Mota, Instituto Nacional de Pesquisas da Amazonia - INPA / Laboratório de Ecofisiologia e Evolução Molecular- LEEM; K. Brix, EcoTox / Marine Biology and Ecology; R. Duarte, São Paulo State University UNESP / Institute of Biosciences; S.D. Smith, Wilfrid Laurier University / Department of Chemistry; A.L. Val, Instituto Nacional de Pesquisas da Amazonia - INPA / CBIO
Dissolved organic matter (DOM) is known to alter metal bioavailability to aquatic organisms, by effectively binding them in natural waters. For some metals (e.g. Cu), this effect is so considerable that it is incorporated into bioavailability-based models (e.g. Biotic Ligand Model, BLM), used to assess the environmental risk of metals in various legislations (e.g. EU Water Framework Directive). However, most of the research on this topic is on temperate regions, while tropical biomes and fish species have been far less studied. This paucity of data contributes to the great gap in developing site-specific water quality criteria in these ecologically important regions. Today, there is a need to better characterize how bioavailability concepts apply to these unique environments, notably with respects to metal-DOM-fish interactions. In the present study, we investigated how the DOM of the Rio Negro (RN), a major tributary of the Amazon river, affects acute Cu toxicity to a local fish: the cardinal tetra (*Paracheirodon axelrodi*). There is evidence that this RN DOM interacts with fish gills, resulting in a positive effect on fish Na homeostasis, the main target of acute Cu toxicity in freshwater animals. In a previous study, we suggested that this physiological protection may add to the extent of protection offered by Cu-DOM complexation, as predicted by the BLM. The present study aimed at further investigating this potential dual role of the RN DOM against Cu-induced Na imbalances in fish. We acclimated *P. axelrodi* to freshly collected RN water (10 mg L^{-1} DOC) and to a DOM-diluted water (1.4 mg L^{-1} DOC) with equal pH (~ 5.7) and major cations concentration (≤ 40 µM). In both waters, we first measured 3-h Cu-gill uptake within Cu concentration ranges of acute toxicity, using the stable isotope Cu^{65}. We assessed whether gill accumulation followed the determined free Cu^{2+} concentration in the water, in accordance with the BLM. Second, we related these Cu-gill bindings with measured unidirectional Na^+ fluxes at the gills. For these two experiments, various DOM pre-acclimation times of 0, 1 and 5 days were tested. Initial findings suggest that $[Cu^{2+}]$ in the water is a relatively good predictor of Cu-gill binding, which in turn appears to be a good indicator of Na^+ ionoregulatory disturbance. These preliminary results indicate that protection by DOM mainly occurs from Cu complexation under the tested conditions, in support with a key concept of the BLM.

Updating the chronic Copper bioavailability models
C. Nys, Arche consulting / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; P. Van Sprang, Arche consulting; T. Van Regenmortel, Ghent University; S. Lofts, Centre for Ecology and Hydrology / Shore Section; K.A. De Schamphelaere, Ghent University / Department of Applied Ecology and Environmental Biology
The current procedure for deriving bioavailability-based Predicted No-Effect Concentrations (PNECs) for Cu as outlined in the Cu voluntary risk assessment report (Cu-VRAR, 2008) is based on bioavailability-normalisation of chronic toxicity data with chronic Cu bioavailability models for three trophic levels: a *Daphnia magna* Biotic Ligand Model (BLM), an algae generalized Bioavailability Model (gBAM) and a fish BLM. Overall, this work aimed at refining the copper bioavailability models by reviewing and incorporating recent advances in speciation modelling and copper toxicity modelling that have emerged over the past 10 years. Over this period, optimizations of the Cu bioavailability models for fish and *D. magna* have been proposed through the use of generalized bioavailability models. These updated bioavailability models account for other factors that determine the effect of pH on free metal toxicity besides the competitive effect of H^+ at the biotic ligand site, and as such may more accurately predict the effect of pH on Cu^{2+} toxicity than the BLM. In the current Cu-VRAR (2008), chronic bioavailability models are used in combination with WHAM V as geochemical speciation program. However, a more user-friendly version of the Windermere Humic Aqueous Model (WHAM VII) has become available meanwhile. Yet, to be able to update the entire chronic Cu bioavailability normalization procedure to a WHAM VII/gBAM-based approach, a validation of the algae and *D. magna* gBAMs in WHAM VII is still needed. Therefore, we evaluated in the present study whether chronic Cu gBAMs for algae and *D. magna* originally developed in combination with WHAM V can be updated to WHAM VII without compromising on the predictive capacities of the original models. To this extent, we first reparametrized the pH slopes (S_{pH}) of the existing algae and *Daphnia magna* gBAMs based on WHAM VII-calculated free Cu^{2+} activity. Next, it was shown that the newly parametrized WHAM VII-gBAM can be used to predict chronic dissolved Cu toxicity to several model- and non-model-species within 2-fold error. Overall, our analysis showed that the updated bioavailability models for chronic toxicity of copper, based on the gBAM model structure and incorporating a more recent version of the speciation tool (WHAM VII), can be used to accurately predict chronic toxicity to both model- and non-model species. These updated models may be useful for the purposes of environmental hazard and risk assessment of copper.

183
Ecotoxicity of lanthanides to Daphnia magna
D.A. Vignati, CNRS / LIEC UMR7360; C. Cossu-Leguille, B. Sohm, C. Fouque, LIEC Université de Lorraine CNRS; L. Poirier, Univeristé de Nantes / MMS; C. Bojic, LIEC CNRS Université de Lorraine; D. Pauly, LIEC Université de Lorraine CNRS; C. Hissler, LIST Luxembourg Institute of Science and Technology; J.E. Groenenberg, Wageningen University / sustainable soil management; L. Giamberini, Université de Lorraine, CNRS UMR 7360 / LIEC, CNRS
Lanthanides (LNs) are a group of fifteen elements with increasing economical importance in sectors such as clean energy, military industry and agronomy. However, the available information on their ecotoxicity still remains quite limited and only a handful of studies have examined the biological effects of the whole series of LNs. Understanding the ecotoxicity of the entire LN series is important because it is not yet clear if biological effects follow a regular pattern along the series; which may simplify the hazard and risk assessment for this group of elements in the future. In this contribution, the acute toxicity of the entire series of LNs to *Daphnia magna* was evaluated according to the ISO standard 6341 along with a study of the chemical behaviour of LNs in the ecotoxicological exposure medium. ECs50 ranged from 6.8 to 30.5 mg/L (0.075–0.18 mM) after 24h and from 4.3 to 15.7 mg/L (0.04–0.1 mM) after 48h and did not show any clear trend along the LNs series. Total LNs concentrations measured at t=0 agreed with nominal values to ± 20% with the exception of Nd (156%) and Dy (60%). Filterable concentrations decreased by 45–95% after 24 h and by 50–98% after 48 h. Total concentrations after 48 hours remained within 25% of initial values for Nd, Tb, Ho, Tm, Sm and Lu, but decreased by 50% or more for the other lanthanides. Thermodynamic model calculations (VisualMinteq, ver 3.1) indicate that precipitation of LNs carbonates can occur at the elemental concentrations added into the test vessels; in agreement with the experimentally measured decrease of (filterable) concentrations in the test medium. In such situations, ECs50 are better expressed using time-weighted mean (TWM) values that allow to calculate the average concentration to which organisms are exposed over the entire test duration. Using the TWM approach actually reduces the risks of underestimating the ecotoxicity of lanthanides to *D. magna* and hence the possibility of errors in hazard and risk assessement. ECs50 can also be expressed based on the modelled concentrations of the free ionic species (Ln^{3+}) of each lanthanide to facilitate intercomparability between tests and laboratory-to-field extrapolation of standard ecotoxicological results. Care must however be taken in interpreting combinations of model results (valid for thermodynamic equilibrium conditions) and dynamic situations in laboratory and field settings.

184
QICAR as a tool to address the lack of toxicological data for technology-critical metals
S. Le Faucheur, Institute F.-A. Forel, University of Geneva / Département F.-A. Forel des sciences de lenvironnement et de leau; C. Fortin, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; J. Mertens, EPMF; E.J. Van Genderen, International Zinc Association / Associate Director, Environment & Sustainability; A. Boullemant, RioTinto; P. Campbell, Syngenta / Environmental Safety; P. Campbell, Université du Québec / INRS Eau Terre Environnement
The development of new technologies requires the use of metals (Au, In, Ge, platinum group elements) for which impacts on aquatic ecosystems are poorly known. Quantitative structure-activity relationships (QSAR) have been used for many years now to address this issue for newly formulated organic molecules. In the present study, we developed Quantitative Ion Character Activity Relationships (QICAR) to predict the toxicity of technology-critical metals (TCM) towards aquatic organisms based on intrinsic metal characteristics. Twenty-three metal characteristics (e.g.: molecular weight, atomic radius, electronegativity, …) were evaluated as predictors of metal toxicity. Modelled organism responses were the measured acute EC_{50} values of 12 *data-rich* metals for algae, daphnids and fish. Models were constructed with and without species-distinction. Both total dissolved metal concentrations and the free metal ion activities were used to build the QICAR. Prior to model development, principal component analyses were used to highlight autocorrelations among metal characteristics and to reduce the number of entry variables. Simple and multiple linear regressions (stepwise approach) were then constructed and examined for their goodness of fit statistics as well as verified for their linear regression assumptions. Finally, QICAR were tested by comparing the measured and predicted EC_{50} values of the TCM. For QICAR based on the free metal ion activities, linear free energy relationships were additionally built to estimate the binding constants of the data-poor metals with HO^-, CO_3^{2-}, EDTA and Cl^- when these values were lacking. Among the 15 'best' obtained QICARs (adjusted $r^2 > 0.8$), 12 were simple linear regressions with X_m^2r as predictor. This composite parameter (X_m =metal electronegativity; r = metal ionic radius) is a proxy for the metal's ability to form covalent bonds with ligands present in the exposure media and in the test organisms. The toxicity of the TCM was found to be best predicted by the QICAR models based on the total dissolved metal concentration rather than those based on the free metal ion activities. This unexpected result might reflect the fact that the tested *data-poor* metals form poly(hydroxo)-complexes in the exposure media, leaving only very low free metal ion concentrations ($< 10^{-15}$ M). Future experimenters might want to focus on the study of the interactions between such complexes and the test organisms.

185
Use of AF on HC5 for data rich metals, revisiting the evidence !
P. Van Sprang, Arche consulting
Statistical extrapolation in line with the provisions of the WFD-EQS and REACH guidance, namely the species sensitivity distribution method (SSD), can be used for the derivation of EQSs for data rich metals such as Cu or Zn. The median estimate of the HC_5 is proposed as the basis of the EQS/PNEC. According to the requirements set out in the regulation, an SSD can only be constructed when data are plentiful but there may still be some residual uncertainty that needs to be accounted for in the final EQS/PNEC. For this reason, the HC_5 is divided by an additional assessment factor (AF): EQS (or PNEC) = HC_5/AF. The choice of the AF applied to the HC_5 is dependent on the remaining uncertainty associated with the assessment. According to the current approach, metals (or substances) with similar HC_5 and residual uncertainties need to be protected at different levels depending on the NOEC ranges, ie. a metal with a narrow range of NOEC request a higher protection level than a metal with a broader range of NOEC values. However from a scientific perspective, similar protection levels are deemed to apply for substances with similar HC_5 and residual uncertainties. Moreover, the current approach does not consider the sensitivity (ie. slope) of the SSD as it derives similar EQS/PNEC for SSD with very different slopes. Therefore, an alternative approach is proposed to derive safe threshold concentrations for data rich metals/substances. In this new approach it is proposed to apply the AF directly on the protection level or PAF (Potentially Affected Fraction) value (ie. 5% according to the regulation) rather than on the concentration derived from the protection level, ie. the HC_5. To assess how this newly proposed approach would affect the setting of EQS/PNEC values, different real world examples have been assessed. As an example, the SSD of Zn have been re-evaluated for EQS/PNEC setting. In the current REACH/WFD methodology, a HC_5 of 0.0156 mg/L has been calculated. Considering an additional AF of 2, this is resulting in a EQS/PNEC of 0.0078 mg/L (Zn RAR, cfr. EC, 2004). However, applying the newly developed approach on the Zn SSD would result in a EQS/PNEC value of 0.0117 mg/L. Similar findings were observed for Ag, where a EQS/PNEC of 40 ng/L is reported in the REACH dossier, while a EQS/PNEC of 60 ng/L is calculated from the newly developed approach.

Modelling and Monitoring of Pesticides Fate and Exposure in a Regulatory Context (I)

Updates on Surface Water Model Development in China for Higher Tier Environmental Risk Assessment
Y. Wang, Syngenta Crop Protection; W. Chen, Syngenta Crop Protection Inc.; J. Zhou, Nanjing Institute of Environmental Sciences, MEP
Here we update the findings from a science collaboration project between Nanjing Institute of Environmental Science (NIES), China and Syngenta. The aim of the project is to support the development and evaluation of dry-land surface water modelling in China for higher tier environmental risk assessment for plant protection product registrations. Local dry-land field data including soil, weather, hydrological data, and agronomic practice information have been collected by NIES for eight sites representative of Chinese agricultural areas. All data were processed and parameterised in PRAESS taking into consideration a vast database of scientific literature and in depth knowledge of European and American environmental risk assessment approaches. Head-to-head comparison between PRAESS and EU FOCUS surface water model, has given some confidence in the model performance. Future recommendations for higher tier risk assessments in China are bridged with a European higher tier case study. In this case study, exposure profiles derived from FOCUS surface water modelling outputs were combined with toxicokinetic and toxicodynamic models as a weight of evidence to demonstrate safe use and maintain registration in Europe. This science collaboration work has laid a solid foundation for a Tier II surface water model acceptance for refining product regulatory assessments in China. The European case study provides a useful and forward-looking framework to further develop refinement methodologies for ecological risk characterisation in China; thus, appropriate protection goal and definition settings are essential for ecological risk assessment.

187
A critical reflection on the use of Briggs´ equation in pesticides regulation
K. Kuppe, Umweltbundesamt / Plant Protection Product; I. Bonath, Federal Environment Agency / Section IV 1.3 Pesticides - Fate and Behaviour & Groundwater Risk Assessment; H. Banning, German Environment Agency UBA / Plant Protection Products; A. Nehls, German Environment Agency UBA; C. Pickl, German Environment Agency UBA / Plant Protection Products
Briggs *et al.* (1982) examined the relation between TSCF and the octan-1-ol water distribution coefficient logKow based on experimental uptake data for 18 substances. The authors found a bell shaped correlation and derived a respective equation. This equation was later applied as standard procedure to obtain TSCF values for groundwater modelling in ppp regulation. Using the substance specific logKow, TSCF values can be calculated individually. A general TSCF value of 0.5 was derived as the approximate average from this study and was established as a default TSCF for systemic, non-ionisable substances in groundwater modelling in ppp regulation. For non-systemic and ionisable substances a default of 0 was recommended (FOCUS, 2000, p. 94; FOCUS, 2002, p. 38). Since the publication of the original paper in 1982, more data on plant uptake of chemical substances has become available. The correlation of the uptake to one single factor, the logKow, has been queried by several authors, e.g. due to the lacking precision of single-parameter relationships and the limitation of these relationships to a wide variety of contaminants and plants species (Bagheri *et al.*, 2019). Trapp and Pussemier (1991) measured the uptake of carbamates in bean plants and concluded that the Briggs equation does not fit the data. The authors discussed the possibility that the difference might have been caused by different lipid contents of the bean plants and the barley plants used by Briggs. Dettenmaier *et al.* (2009) analyzed 126 TSCF values of 115 substances from various studies and found a high variability. The relation between logKow and TSCF, as reported by Briggs (1982), was not confirmed. An even bigger dataset was analyzed by Doucette *et al.* (2018). The authors separated neutral from ionisable compounds and linked them to the empirical relationships described by Briggs (1982) and Dettenmaier *et al.* (2009). Compared to the dataset of Dettenmaier *et al.* (2009), the scatter is reduced. However, a clear relationship between the TSCF and the logKow has also not been established. In our presentation we review and analyze available data and demonstrate why we conclude that neither the Briggs equation nor the default of 0.5 are adequate and conservative enough to be used in groundwater simulation models. Consequently, there is an urge to reject the temporary regulatory approach to use of TSCF values based on the Briggs equation.

188
DEVELOPMENT OF A OECD TEST GUIDELINE TO DETERMINE PLANT ROOT UPTAKE FOR REGULATORY ENVIRONMENTAL FATE MODELLING
M. Lamshoeft, Bayer CropScience AG / R&D; K. Kuppe, Umweltbundesamt / Plant Protection Product
A novel OECD study design is currently under evaluation by a group of experts from academic, industry and regulatory, which can be used to quantify uptake of chemicals via the root system of plants. Ten laboratory organizations with different levels of experience with uptake testing will participate in a round robin test and study uptake of [^{14}C]-1,2,4-triazole by oilseed rape and wheat plants. The

aim is to examine the reproducibility of the results obtained with the proposed study design and their reliability for regulatory purposes. The study design has already been tested investigating uptake of different compounds (molecular weight: 114 to 563 g/mol; log Kow: -1.5 to 2) by wheat, tomato and potato plants. Furthermore, the design may not be appropriate for volatile compounds, highly phytotoxic compounds, or quickly degrading compounds. At the moment the study design has been tested using wheat, potato, tomato and oil seed rape plants, but is not limited to these. To explore the possible impact of different soil pH´s, the experiments will be conducted at two pH values: pH 5.5 and pH 7.0. The The plant uptake factor (PUF) and the transpiration stream concentration factor (TSCF) will be calculated for the three different incubation periods ending after t = 2, 4 and 6 days according to the following equations that consider the concentration development over the course of the incubation. The envisaged study design was explicitly developed to address the need identified by EFSA and was based on suggestions from the EUregPUF workshop (York, 2013) where participants from academia, authorities and industry met to establish an up to date understanding of plant uptake science. Lessons learned from the testing and continuous exchange with academia and authorities facilitated optimisation of the study design. Critical issues that were already identified within the OECD process (e.g. a possible concentration dependence of the uptake or the duration of the experimental phase) will be investigated and discussed. The current version of the study design is evaluated during the course of the OECD process to answer the question if the test design can be considered appropriate to produce reliable data on plant uptake to be used as input for refined exposure modelling. An explicit guidance, on how to integrate the requested study design into the regulatory process is aimed to be developed based on the outcome of the final OECD test guideline.

189
Model comparison of the effects of plant uptake on the environmental fate of three anonymised pesticide compounds
B.M. Jones, A. Verhoef, University of Reading / Department of Geography and Environmental Science; C.D. Collins, Reading University / Soil Research Centre
The potential hazards of plant protection products (PPPs) require regulation via pesticide registration which requires a simulation of their environmental fate. Within the EU regulatory framework, the working group FOCUS (FOrum for the Co-ordination of pesticide fate models and their USe) proposed the main regulatory models to be PEARL, PELMO and MACRO, with PRZM being used sparingly. A lack of consistency and reproducibility in experimental laboratory plant uptake factor (PUF) tests has led to low confidence in the ability to determine a consistent PUF value. Regulatory advice now states that plant uptake within pesticide fate models should be set to PUF = 0 unless the compound is known to be systematic, at which a PUF = 0.5 value is supplied. Despite this, only a small amount of work has been conducted with regards to the effect of plant uptake on Predicted Environmental Concentration in Groundwater (PEC_{GW}). This study addresses how the outputs of different pesticide fate models depend on changes in PUF, and what implications this could have for environmental fate modelling going forward. PEARL and PELMO were selected for this study given their varied approaches to modelling the soil water balance and dynamics. A systematic approach was taken to scenario selection, with Eurostat databases providing crop production and pesticide sales statistics, which were used to rank the locations and select those appearing highest for both categories. Compounds were selected to represent a range of mobility and persistence values, therefore, a range of soil adsorption coefficient (K_{OM}), half-life (DT50) and PUF values were used, with all other parameters being kept constant. Both models were run for 26 years, with a daily time step, and a 6-year warm-up period included. Comparisons of the outputs show that both models behave very differently across locations; this appears to be particularly true for sandy soil profiles with high irrigation inputs over the summer. The effect of plant uptake (modelled from 0 to 1) on PEC_{GW} values in PEARL has a range of 5%-38%. Results from this study show that agreement between both models is highly dependent on physical soil properties and this requires further study. *Acknowledgements* – BBSRC for funding this project and Syngenta for being a CASE partner.

Introducing PERSAM v3.0: a tool for predicting environmental concentrations in soil
I. Joris, L. Decorte, S. Van Looy, J. Bronders, VITO
European pesticide authorisation requires risk assessment procedures using standardised exposure scenarios developed by the European Food Safety Authority (EFSA). Recently EFSA produced a revised Guidance Document providing guidance for the exposure assessment of soil organisms to plant protection products (PPPs) and their transformation products in accordance with Regulation (EC) No. 1107/20091 of the European Parliament and the Council. Guidance is provided for all types of concentrations that are potentially needed for assessing ecotoxicological effects, i.e. the concentration in total soil and the concentration in pore water, both averaged over various depths and time windows. The guidance considers both permanent crops and annual crops. The goal of the exposure assessment is the 90th percentile of the exposure concentration in the intended area of use in each of the three regulatory geographical zones (North, Centre, South) or in a selected EU country. The recommended exposure assessment procedure consists of four tiers where all tiers aim to assess the same exposure assessment goal. In higher tiers of the exposure assessment, crop interception and subsequent dissipation at the crop canopy may be included. Given the complexity of the calculations and parameter selection in the different tiers, efficient use in the regulatory process requires the development of software tools. PERSAM was developed to assist the user in performing calculations using the analytic model, as described in the guidance document and the latest release is developed in line with the revised guidance. The software is able to calculate (i) Tier-1 predicted environmental concentrations (PECs), (ii) Tier-2 95th-percentile PECs and to (iii) select the grid cell (including the scenario properties) corresponding to the 95th-percentile PEC as needed for the scenario development at Tier 3A. PERSAM can also generate a so-called transfer file that can be read by the numerical models described in the Guidance Document. PERSAM generates reports intended for regulatory submissions. The concepts of the calculation procedure will be discussed and the software will be demonstrated with particular attention for the new features compared to previous versions of the software.

Metaldehyde dynamics in a small agricultural catchment
M. Whelan, University of leicester / Geography; A. Ramos, Cranfield University / Water Sciences; I. Guymer, The University of Sheffield / Civil Engineering; R. Villa, Cranfield University / Water Sciences; B. Jefferson, Cranfield Univeristy / Water Sciences
Pesticides make important contributions to modern agriculture but losses from land to water can present problems for environmental management, particularly in catchments where surface waters are abstracted for drinking water. In the UK, one of the most problematic pesticides facing water companies is metaldehyde – the active substance commonly used in slug pellets, which unusually difficult to remove via conventional drinking water treatment. A better understanding of metaldehyde dynamics is often hampered by low sampling frequencies. Here, we present a study of metaldehyde dynamics in a small (3.9 km^2) surface water catchment in Cambridgeshire, UK using a combination of high frequency in-stream monitoring and numerical modelling. Discharge was measured continuously at a Venturi flume. Water samples were collected every eight hours and analysed for metaldehyde using direct injection LC-MS. A simple conceptual hydrological and pesticide transport model was employed based on continuous root zone water balance calculations. Metaldehyde losses are calculated based on the displacement of a limited fraction of the soil pore water during rainfall events occurring after application. Metaldehyde pellets were applied in the second week of August 2014 to an unknown fraction of the catchment. Measured concentrations in stream water increased markedly in early storm events (to about 9 mg L^{-1}). Thereafter, concentrations “rachet down” in successive events - responding to rainfall but not to the same levels (i.e. reflecting an effective exhaustion in soil supply as a consequence of in-field degradation and dissipation). Insights derived from the application of the model to the study catchment will be presented.

Fish Model Species in Human and Environmental Toxicology (I)

192
Sex Related Gene Expression Patterns in Zebrafish at Different Ages
A. Zenker, University of Appl. Sc. Northwestern Switzerland / Institute of Ecopreneurship; M. Gut, University of Appl. Sc. Northwestern Switzerland / School of Life Sciences
Fish embryos have been used to determine acute toxicity in fish embryo acute toxicity test (FET) and to measure effects of substances in the early life stage toxicity test (ELS). In contrast to rodents, one disadvantage to the application of fish toxicity tests is that gender-based selection of individuals cannot be done before or after the test. Consequently, the data obtained contains a mixture of male and female effects. This is important to note as several zebrafish studies showed gender differences. In contrast to the otherwise well-established gene annotation, *Danio rerio* still lack any clearly-defined sex-determining genetic loci. Recent studies suggest a polygenetic sex determination, where the genes influencing the sex-determination are distributed throughout the whole genome. In this study gene expression patterns of nine genes contributing to the sex determination and gonad differentiation, namely *sox9a, sox9b, dmrt1, cyp19a1a*, *cyp19a1b, cyp17a1, nr0b1, igf3* and *vtg1,* were determined by qPCR in zebrafish embryos which had been treated with beta-oestradiol or testosterone and also in different aged zebrafish. Although some of the genes showed sex-specific expression (*cyp17a1, vtg1* and *cyp19a1a),* no defined expression pattern could be observed to distinguish sex in neither larval stage nor juvenile zebrafish.

193
Map and Model - how to make zebrafish toxicogenomics more predictable
A. Schuettler, Helmholtz centre for environmental research - UFZ / Bioanalytical Ecotoxicology; R. Altenburger, Helmholtz Center for Environmental Research -

UFZ / Department Bioanalytical Ecotoxicology; J. Krüger, Helmholtz Center for Environmental Research - UFZ; K. Reiche, Fraunhofer Institute for Cell Therapy and Immunology / Bioinformatics Research Unit Department of Diagnostics; W. Busch, Helmholtz centre for environmental research - UFZ / Bioanalytical Ecotoxicology
Toxicogenomic methods using model organisms like the zebrafish are discussed to provide improved assessment of chemical related hazards or environmental health. At the same time, toxicogenomic data bear the challenge of comparing and interpreting highly complex molecular profiles, even when considering only one exposure condition. The integration of time or concentration dependent measurements even adds another layer of complexity. In order to improve comparability between toxicogenomic experiments we developed an experimental and bioinformatic pipeline to obtain dynamic toxicogenomic fingerprints of chemicals. We exposed zebrafish embryos (ZFE) to a range of five different concentrations of the substances diuron, diclofenac, and naproxen, and measured the transcriptome at five time points. The measured fingerprints were projected to an universal coordinate system (zebrafish toxicogenomic universe), based on a self-organizing map of compiled toxicogenomic data from public databases. Subsequently, we applied regression modeling to get a quantitative description of the time and concentration dependent responses. The resulting toxicogenomic fingerprints allow three dimensional inference on the concentration as well as the time scale to conditions not measured. Furthermore, the toxicogenomic universe allows to integrate extensive toxicogenomic information. Taken together this novel approach facilitates comparison between different fingerprints (and different studies) as well as between the responses of different clusters in one fingerprint. For our investigated substances we could identify and quantitatively describe the dynamics of key events in response to the exposures (related to e.g. developmental delay, stress response and cox inhibition) and discriminate between stage dependent and exposure dependent events.

194
Toxicity and metabolomics exposure studies of zebrafish to PFASs and alternatives - chemical alternatives assessment approach
P. Leonards, VU University, Institute for Environmental Studies / Department of Environment and Health; R. Rodrigues, J. Legradi, VU University
Perfluorinated compounds (PFCs) are widely used as surfactants in industrial and consumer products, commonly as repellants in textiles, fire retardants and food packaging. However, many PFCs show to be persistent in the environment. In this study, chronic and acute exposures of PFOA, PFOS and its alternatives PFHxS, PFBS, GenX, D4, D5 and TMS were assessed. In this study we performed a chemical alternatives assessment strategy to compare the affected metabolomic pathways between PFOA, PFOS and the alternatives to assess more human and environmentally friendly compounds. Chronic and acute exposures of PFOA and PFOs and its alternatives PFHxS, PFBS, siloxanes (D4, D5 and TMS), and GenX were assessed using embryo (*Danio rerio*) to study the mechanism of toxicity and study if PFHxS, PFBS, and siloxanes are feasable alternatives. Zebrafish embryos were exposed to PFOA, PFHxS, PFBS, PFOS, GenX, D4, D5 and TMS, and the swimming activity and locomotor activity were recorded. No significant effects in mortality, developmental abnormalities, and swimming activity were observed in the exposed groups of all compounds. qPCR and metabolomic analysis showed that transcription of the DNA damage gene was significantly up-regulated for PFOA, PFHxS, PFOS and Genx. Interestingly, the lipid metabolism gene was up-regulated for PFOS and GenX. In the acute exposure, all compounds significantly affected phosphatidylcholines (PC) lipids, and PFOA, PFHxS and PFBS affected phosphatidylethanolamines (PE). In the chronic exposure, PC and PE were also affected, however, in contrast to the acute exposure, chronic exposure affected the triacylglycerols (TAG) and sphingomyelins (SM). TAG function as energy reserve and their metabolism plays a key role in cellular energy balance, lipid homeostasis, growth, and maintenance. The results showed that exposure to PFCs and their alternatives induce changes in lipid metabolism, mainly the glycerophospholipids pathway. The zebrafish embryo test showed to be a suitable assay for testing the toxicity and mode of action of environmental toxicants. Based on the results of this study, alterations in lipid metabolism (glycerophospholipids) is a metabolic pathway affected by both PFASs and their alternatives. The alternatives D4, D5 and TMS appears to have a lower impact on metabolic pathways (e.g. lipids) than PFOA.

195
Differences in POPs, transcriptome and proteome of wild and hatchery-reared Baltic Salmons
M. Kanerva, T.M. Nguyen, Ehime University / CMES; T. Kunisue, Ehime University / Center for Marine Environmental Studies; K.A. Vuori, University of Turku / Department of Biology; H. Iwata, Ehime University / CMES
Despite conservation, the marine survival rates of both wild and hatchery-reared Baltic salmon (*Salmo salar*) are declining and lower survival is especially a problem with reared fish. Although some studies on the molecular level differences in wild and aquacultured Atlantic salmon has been done, there isn’t many on the Baltic populations. Salmon samples were collected in the years 2007 and 2008 from Baltic main basin (BMB), Bothnian Sea (BS) and Gulf of Finland (GoF). Liver from wild and reared salmon from each area were used for transcriptomic, proteomic and POPs analyses. POPs levels between wild and reared salmons showed a statistical difference only in the GoF for dioxin-like and non-dioxin-like PCBs. Comparison among areas showed that dioxin-like PCBs were significantly higher in GoF than in BMB or BS, while non-dioxin like PCBs were higher in BS than in GoF or BMB. Chlordane levels were higher in BS than in GoF and BMB, while o,p’-DDT and p,p’-DDT showed an opposite trend. BS had the highest number of DEG when comparing wild and reared salmons, followed by GoF and BMB. For DEP the order was GoF>BS>BMB. When comparing different areas within wild fish, BMB vs GoF had the most DEG, followed by BMB vs BS and BS vs GoF while for DEP the order was BMB vs BS>BS vs GoF>BMB vs GoF. For reared salmon, BMB vs GoF had the highest number of DEG and DEP, followed by BS vs GoF and BMB vs BS. In the comparison of wild vs reared salmon transcrptome, lipid metabolism pathways were enriched in BS and GoF, no enrichements were found in BMB. In wild salmons from different areas, main pathways were cell growth and death and signal transduction in BMB vs BS or GoF, while in BS vs GoF, lipid metabolism was enriched. In reared fish, lipid metabolism pathways were the most enriched in all areas. For proteome the enriched pathways were various amino acid metabolism. Only GoF showed significant enrichment between wild and hatchery reared salmon. Between areas wild salmon of BMB vs BS and reared fish of BMB vs BS and GoF showed significant enrichment. Cell cycle and apoptosis and lipid metabolism related transcription factors were the most abundant in all comparisons. There was high correlation in the variances of POPs with both transcriptome and proteome data. The highest number of transcripts were associated to non-dioxin-like PCBs and PBDEs, and proteins to PBDEs and chlordane. In general the difference caused by areas were bigger than those between wild and reared salmon.

196
Toxicity evaluations in medaka embryos exposed to chlorophenols using GC/MS metabolomics and explorations of its differences by chlorination position
S. Uno, Kagoshima University / Faculty of Fisheries; E. Kokushi, Kagoshima University / Education and Research Center for Marine Resources and Environment
Chlorophenols are one of the most common chlorinated aromatic hydrocarbons in the environment, because they are anthropogenically discharged in industrial wastes and are also generated by the degradation of chlorinated pesticides. But there have been few researches on the effects in aquatic organisms. Metabolomics can provide information about the metabolic processes that are occurring in an organism and have proven to be a highly sensitive method even for detecting the effects of toxicants. Previous studies have suggested that metabolite variations can indicate toxic exposure earlier than typical measurable endpoints such as growth inhibitions. In this study, we exposed CPs such as 2,4-dichlorophenol (24-DCP), 2,6-dichlorophenol (26-DCP), 3,5-dichlorophenol (35-DCP), and 2,3,4-trichlorophenol (234-TCP) to the embryos of Japanese medaka (*Oryzias latipes*), and evaluated their effects during the embryonic development using GC/MS metabolomics. Additionally, the differences of toxicities by chlorination position on CPs were examined with metabolomics approach. Medaka embryos were exposed to individual CPs such as 24-DCP: 6.25 mg/L, 26-DCP: 6.25 mg/L, 35-DCP: 2mg/L, 234-TCP: 0.16 mg/L, and each 1/10 of their concentrations, respectively. Embryos were kept in test water spiked with CPs (n=6). Control group, in which embryos were kept with CPs free water, was also established. Embryos were collected at 3, 4, and 6 days after the start of the exposures. Metabolites were extracted from embryos and mesured by GC/MS. The individual areas obtained from all metabolites detected on a GC/MS chromatogram were analyzed by ANOVA among each exposure and control groups. Metabolites with significant differences in ANOVA were selected, and their areas were followed to analyze by principal componet analysis (PCA). CPs exposures had caused several effects in embryos and hatching larvae. Metabolomics approach shows that the toxicities have already appeared at 3 days after the start of the exposure. PCA score plot at 6 days showed that the order of severity of each toxicity and that was 26DCP< 24DCP< 35DCP< 234TCP. As a result, the increase of the number of chlorine could cause more severe toxicity. As a result, the CP toxicities were suggested to be decided by the number of chlorine and the chlorination position.

Life Cycle Impact Assessment (I)

198
Product Biodiversity Footprint – A novel approach to compare the impact of products on biodiversity combining Life Cycle Assessment and Ecology
A. Asselin, Consultant; S. Rabaud, C. Catalan, B. Levêque, I Care & consult; J. L'Haridon, LOréal Research & Innovation; P. Martz, LOréal Research & Innovation / LOREAL; G. Neveux, I Care & consult

Product impacts on ecosystem quality have long been addressed by the top-down approach known as Life Cycle Assessment (LCA). Impacts are most of the time assessed within the "biodiversity loss" damage category indicator. However, LCA methods do not cover the 5 drivers of biodiversity loss as identified by (Millenium Ecosystem Assessment, 2005) (MEA): only land occupation and transformation, pollution, climate change are covered, species overexploitation and invasive species are not. Besides, ecologists work on the ground to measure concrete impacts from given practices on biodiversity in a given area, in a more bottom-up approach, for some parts of the value chain of the product (e.g. production of agricultural bio material). The Product Biodiversity footprint (PBF) approach aims at bridging the gap between LCA and ecology. Its objective is to allow comparison of variants of a product for eco-design, being to our knowledge the first method to address the five drivers of MEA. The methodology combines LCA and ecology and organizes them towards practical indicators and representations for business decision. The general architecture is represented by three modules : i) Module 1 computes life cycle impact assessment; ii) Module 2 refines the quantification of the pressure on 'habitat change', using specific information on practices including ecological data; this second Module, combined with Module 1, allows comparison along the value chain for MEA drivers from habitat change, pollution and climate change ; iii) Module 3 qualitatively assesses aspects that are not included in LCA models, with 'species management' and 'invasive species' indicators, allowing comparison for those two remaining MEA drivers. PBF has been tested in three business case studies. It demonstrates that the integration of ecological data enables to specify LCA results and suggests that current LCA methods tend to overestimate impacts on biodiversity caused by agriculture when "biodiversity-friendly" practices are implemented. However, this method is dependent on the available data/literature connecting specific practices and biodiversity, calling for streamlined data gathering as a potential next step. The method and the main outcomes of the case study conducted with L'Oréal on a simplified shower gel will be presented.

Incorporating habitat fragmentation into the characterisation of land use impacts on biodiversity

K. Kuipers, Norwegian University of Science & Technology (NTNU) / Energy and Process Engineering; M.A. Huijbregts, A.M. Schipper, Radboud University Nijmegen / Department of Environmental Science; R.F. May, Norwegian Institute for Nature Research / Terrestrial Department; B.J. Graae, Norwegian University of Science & Technology / Department of Biology; F. Verones, NTNU / Department of Energy and Process Engineering

For the credibility of LCA, it is important to cover the most relevant impact pathways adequately. Since habitat loss is the main driver of global species loss, it is crucial to appropriately characterise land use and land use change impacts on biodiversity. However, virtually none of the currently operational LCIA models considers spatial habitat configuration and fragmentation aspects (but see Larrey-Lassalle et al. 2018), which are recognised as important factors for the survival or extinction of species. Including fragmentation and the spatial composition of the landscape is especially relevant when the landscape (e.g., ecoregion) consists of a distribution of various hospitable habitats, separated by hostile land cover types. We explore methods to quantify habitat loss and fragmentation impacts conforming the LCIA framework such as the fragmented landscape species- area relationship (FL-SAR; Rybicki & Hanski 2013), the countryside species-fragmented area relationship (c-SFAR; Larrey-Lassalle et al. 2018), and methods based on field monitoring data. Furthermore, we propose a new regionally and taxonomically specific impact model with global geographical coverage that quantifies the regional impacts of habitat loss and fragmentation on groups of species that differ in traits relevant for responses to habitat change in multi-habitat landscapes (e.g., habitat preferences, home ranges, and dispersal capacities). Separating the taxonomic groups based on species traits allows for a tailored calculation of the impacts of loss and fragmentation of various land cover types on biodiversity. Subsequently, these regionalised (gridded resolution) and species-category specific impacts are aggregated to broader taxonomic groups (e.g., mammals or birds) and bigger spatial units (e.g., ecoregions). The resulting spatially and taxonomically differentiated characterisation factors will be of high value for regionalised LCIA land use impact modelling. **References:** Larrey-Lassalle P, Loiseau E, Roux P, et al (2018) Developing characterisation factors for land fragmentation impacts on biodiversity in LCA: key learnings from a sugarcane case study. Relevance of considering LCA and ecological expertise methods to evaluate biodiversity impact of green roofs

A. BRACHET, CSTB; M. OLMOS, CSTB, MNHN; N. SCHIOPU, CSTB; P. CLERGEAU, MNHN

Human activities are inducing the sixth Earth's biodiversity mass extinction due to the global acceleration of species disappearance. As a response to biodiversity erosion, more and more urban planners are preconizing the integration of green roofs in European urban projects. Although these initiatives are welcomed, the objective assessment of their actual impacts is rarely carried out. One can distinguish between "*in situ*" biodiversity impacts (impacts on the construction site) and "*ex situ*" biodiversity impacts (impacts due to the extraction of the raw materials, their transformation, etc.). Usually, the assessment of the "*in situ*" impact on biodiversity is carried out based on the ecological expertise method. This method consists of performing a site's state by naturalistic inventories before and after a perturbation. Meanwhile, LCA is recognized by the European Commission as the best tool to assess the environmental performance of a product along its entire life cycle and enables to assess both "*in situ*" and "*ex situ*" impacts. However, LCA "*in situ*" biodiversity indicator is not in accordance with site observations and do not reach a scientific consensus. Improvements need to be made, especially to correct the lack of local specificities' consideration. The aim of this study is to evaluate the biodiversity footprint of two types of green roofs located in Paris: extensive and intensive green roofs. This study owes its originality into the calculation of the overall impacts of green roofs on biodiversity. A correction of the LCA "*in situ*" biodiversity indicator is proposed through the use of ecological observations. This study proves the relevance of considering both LCA and ecological expertise approaches to evaluate the biodiversity. Depending on the approach chosen, conclusions about the overall biodiversity impact (i.e. "*in situ*" + "*ex situ*" biodiversity) are different. According to the LCA approach, the extensive green roof induces less biodiversity loss than the intensive one. When replacing the "*in situ*" result calculated by LCA method with the one calculated with ecological obervations, the difference between the two green roofs is not significant and thus, their footprints have the same impact order of magnitude. In urban planning, attention has to be payed to not promote the "*in situ*" biodiversity at the expense of the "*ex situ*" biodiversity, and vice-versa.

Inclusion of spatial configuration in LCA by a measure of the pressures on the land use's context -- the case of quarries worldwide

C. Coelho, University Stuttgart, GaBi; J.P. Lindner, Bochum University of Applied Sciences; O. Michelsen, Norwegian University of Science and Technology / Industrial Ecology Programme

The need to draw a land use map which includes measures of fragmentation and landscape configuration has been previously identified by the life cycle assessment (LCA) community. The inclusion of fragmentation in LCA has been limited to ecosystems with natural vegetation cover of less than 30% and applied to forest ecoregions. Other forms of landscape configuration caused by anthropogenic activities can occur also in areas with higher habitat coverage, such as perforation (e.g. mines in remote areas). In such situations, the land use area is often negligible compared to other major land uses such as agricultural land, and are consequently overlooked in LCA. So far LCA biodiversity characterisation factors do not explicitly account for the environmental quality of habitats in the immediate surroundings of a land use activity. Here we attempt to close this gap by considering the context surrounding the land use in question. Due to the difficulty in explicitly assessing habitat suitability consistently and at global scale we propose the use of the cumulative human pressure in the surrounding area as a proxy for its habitat quality. Here we use the Human Footprint Index map (HFI) assuming that, generally, for lower human pressures higher will be the habitat quality and lesser will be the habitat fragmentation. The proposed modelling procedure is as follows: 1) for a given land use activity, the spatial data for the location of these activities is obtained using geospatial information systems 2) a buffer of 1km outside the area of the activity is created, 3) and the statistics of the HFI for the buffered areas is calculated. We applied the model on more than 114.000 quarries worldwide. We established a conversion to a perforation potential, from 1 to 0, being 1 the maximum perforation and 0 no perforation, with the fit of a smooth curve for HFI from 0 to 11. The model's intended use is as an add-on to other LCA methods as opposed to a standalone impact category for the impact of land use on biodiversity. The goal is to provide an improvement for the quality axis in the LCA land use framework. The model brings value to LCA by allowing an explicit identification of activities which potentially cause perforation, being particularly relevant for mining activities in remote areas

202

A regionalised method to assess irrigation-induced soil salinisation in LCA

M. Núñez, IRTA / Chair of Sustainable Engineering; M. Berger, Technische Universitaet Berlin / Chair of Sustaiable Engineering - Office Z1; M. Finkbeiner, DaimlerChrysler AG / Chair of Sustainable Engineering

Soil salinisation is one of the main causes of soil degradation, adding to other soil quality threats like erosion, compaction and loss of organic matter. Soil salinisation is the result of accumulation of salts in soils (mainly Cl, Mg, SO4, K, Na and HCO3). This may happen through different mechanisms, being one of the main anthropogenic reasons the use of poor quality irrigation water and improper agricultural practices. Soil salinisation becomes a problem for global agriculture when the accumulation of salt in soil exceeds a level that affects soil properties and crop production on the long term. Despite the hazard that soil salinisation entails for agri-food systems, to date this environmental problem cannot be assessed in life cycle assessment (LCA) studies because i) no global life cycle impact assessment (LCIA) method for irrigation-induced soil salinisation has been developed; ii) commonly used life cycle inventory (LCI) databases, such as ecoinvent, miss information on salt emissions to soils. This work fills these gaps by providing: i) worldwide and regionalised characterisation factors (CFs) to assess soil salinisation impacts in terms of soil salinisation susceptibility (midpoint indicator) and crop diversity loss (endpoint indicator). Native resolution of CFs is 5 minutes and they were aggregated at subregion and country levels to facilitate the impact assessment of agricultural processes which exact location is unknown; ii) a LCI tool with information on salts emitted with irrigation water per crop yield (kg salt emitted/kg crop) per country and 160 crops, covering most harvested mass on global cropland, is also provided. The modelling of the CFs was done using world maps on soil properties and literature of crop production in salt-affected soils. The LCI dataset builds on information available in the ecoinvent database and complemented with information on regional water supply mixes, water quality of different water sources and average agricultural practices. In summary, the LCA model developed allows assessing, for the first time in LCA, soil salinisation impacts of different cultural practices, namely distinguishing between crops, irrigation technologies and use of leaching and drainage systems, in any location of the world.

203
Process-specific impact assessment instead of region-specific: the case of crop production and AWARE water scarcity factors
A. Boulay, CIRAIG - École Polytechnique de Montréal / Chemical engineering department; L. Lenoir, CIRAIG Polytechnique Montreal
Regionalisation of impacts for water use in LCA is essential, but including regionalisation in LCA inventories, specially for background processes in LCA, is challenging and time consuming, and often data is not readily available. Agricultural processes that require irrigation are the largest water consumers in the world, and often take place upstream of production processes of manufactured goods, hence increasing the challenge for regionalised data collection. Different agricultural products consume water in distinct regions of a country represented by distinct AWARE factors. When sub-national regional information is not available for the inventory, crop-specific factors at the country scale would be a better proxy than generic, or even agri specific factors. Such factors are calculated using data on crop-specific water consumption as a weighting scheme for the annual watershed-based AWARE factors. The results are crop-specific annual and country-scale AWARE characterization factors for 26 crops or different crop groups. The large variation of factors shows the relevance of using such factors when sub-national inventory data is not available. The average difference across 224 countries between the highest and lowest crop-specific AWARE factor is 12.6, with the highest values being 95.9, 77.0, 72.6, 65.9 and 58.7 for Italy, Australia, South Sudan, Argentina and USA respectively. This means that in these regions, the information on the type of crop you are growing can influence your water scarcity results even moreso than the country your activity is taking place in. The calculated factors are used to calculate the water scarcity footprint of maize, rice, soybean and wheat per producing country, in m^3 world-eq per ton of crop produced in country x. When regionalisation of impact assessment is not possible, using crop-specific characterization factors is a good alternative to capture the spatio-temporal variability of water scarcity impacts, although only spatial variation could be integrated here due to lack of temporally explicit irrigation data. This was applied to crop production but could be extended to other water intensive sectors, such as energy or mining.

Towards a Sustainable Development of River-Sea Systems (RSS) and Coastal Areas (I)

Achieving water quality goals for coastal and estuarine ecosystems: Case study of ambient monitoring in Sinclair and Dyes Inlets in the Puget Sound, WA, USA
R. Johnston, Applied Ecological Solutions / Marine Environmental Support OfficeNW; G.H. Rosen, SPAWAR Systems Center San Diego / Energy and Environmental Sustainability; J. Strivens, Pacific Northwest National Laboratory / Coastal Sciences; J. Brandenberger, Pacific Northwest National Laboratory / Marine Sciences Laboratory; M. Colvin, SPAWAR Systems Center Pacific
Achieving water quality goals for coastal and estuarine ecosystems requires an effective monitoring and assessment program to provide metrics that can inform effective management water quality. Here we report on an ambient monitoring program within Sinclair and Dyes Inlets in Puget Sound, WA, USA that was established to characterize environmental conditions, assess potential impacts, and track environmental quality trends within the Inlets. A network of water and biota monitoring locations were selected that were co-located near suspected sources as well as ambient marine and nearshore conditions for periodic sampling. Water column stations and effluents from industrial outfalls were sampled seasonally for trace metals, conventional parameters, and toxicity. Indigenous mussels were sampled biennially for contaminant residues of metals and toxic organic compounds. Results showed water quality in nearshore areas appeared to improve after best management practices for industrial process were implemented. Toxicity from exposure to whole effluent samples was not observed and ambient water samples were not toxic to test organisms, except during the presence of toxic algal blooms. Mussel tissue residues were below effects benchmarks at most locations, however areas with elevated levels of contamination were detected.

Biomagnification of Tantalum through Diverse Aquatic Food Webs
W.E. Espejo, Melimoyu Ecosystem Research Institute / Department of Aquatic Ecosystems; D. Kitamura, Toyo University / Graduate School of Life Sciences; K.A. Kidd, McMaster University / Department of Biology and Canadian Rivers Institute; J. Celis, Universidad de concepcion / Departament of Animal Science, Faculty of veterinary science; C. Galbán-Malagón, Universidad Andrés Bello / Department of Ecology and Biodiversity; R. Barra, University of Concepcion / Department of Aquatic Systems; S. Kashiwada, Toyo University / Research Center for Life and Environmental Sciences; G. Chiang, Melimoyu Ecosystem Research Institute
Tantalum (Ta) is a Technology-Critical Element (TCE) that is growing in global demand because of its use in electronic and medical devices, capacitors, aircraft, and hybrid cars. Despite its economic relevance, little is known about its environmental concentrations and the trophodynamics of Ta in aquatic food webs have not been studied. Invertebrates and fishes from coastal marine food webs representing different climatic zones in northwestern Chile, western Chilean Patagonia, and the Antarctic Peninsula were sampled and analyzed for Ta. The trophic level (TL) of species was assessed with nitrogen stable isotopes (δ15N), and carbon stable isotopes (δ13C) were used to trace energy flow in the food webs. Levels of Ta varied among taxa and sites, with the highest values found in fishes (0.53 – 44.48 ng g-1dry weight) and the lowest values found in invertebrates (0.11 – 43 7.80 n ng g-1dry weight). The values of δ13C ranged from -11.79 to -25.66 ‰. Ta biomagnified in all four aquatic food webs, with slopes of log Ta versus TL ranging from 0.16 to 0.60. This has important implications as little is known about its potential toxicity and there may be increased demand for TCEs such as Ta in the future. Mercury concentrations have decreased in a contaminated area - but where has the mercury gone?
P. Bjerregaard, University of Southern Denmark / Biology; A.J. Markussen, Unity of Southern Denmark / Biology; S.R. Poulsen, University of Southern Denmark / Biology
The western part of Limfjorden, Denmark, Nissum Broad along Harboøre Tange was heavily contaminated with mercury during the 1950ies and 1960ies - mainly due to discharges from the pesticide-producing factory, Cheminova. It is estimated that approximately 30 tonnes of mercury were discharged into the Nissum Broad. Investigations during the 1980ies documented highly elevated concentrations of Hg in sediment and biota along Harboøre Tange; concentrations in sediment with up to 12 μg Hg/g dw exceeded the natural background concentrations by more than 3 orders of magnitude at the most contaminated site; eelgrass (up to 1130 ng Hg g^{-1}) and blue mussels (up to 15 μg Hg g^{-1} dw) exceeded natural background concentrations by up to two orders of magnitude. Recent investigations have shown that mercury concentrations in the sediments along Harboøre Tange have decreased considerably since the 1980ies but concentrations in the benthic fauna are still elevated although they have also decreased since the 1980ies. The purpose of the present investigation was to throw further light on the fate of the mercury in the area. Sediment samples were collected frem the deeper part of Nissum Broad on March 12, 2018, and from the coastal areas of the Broad on April 5-6. The sampling sites were selected to match the sampling sites of as closely as possible. The sediment samples were frozen and freeze dried and the mercury content was determined by means of a Milestone Direct Mercury Analyser (DMA-80). Periwinkles *Littorina littorea* were collected from coastal areas along Harboøre Tange and the northern and southern coast of Nissum Broad. Periwinkles from reference areas without any known history of mercury contamination were analysed for comparison. Mercury concentrations in the deeper parts of Nissum Broad were generally lower than or at the same level in 2018 as they were in the 1980ies – thus showing no indication of movement of mercury from the previosly contaminated sediments along Harboøre Tange to the other parts of Nissum Broad. Mercury concentrations in the periwinkles along Harboøre Tange show almost no overlap with the mercury concentrations in the periwinkles from the reference areas and they appear to be useful sentinels to detect mercury contamination. The reduction in mercury contamination since the 1980ies in the sediments along Harboøre Tange has not resulted in elevated concentrations in other parts of Nissum Broad.

207
Bioaccumulation of rare earth elements in two sentinel species of the Loire

estuary: the European eel (Anguilla anguilla) and the European flounder (Platichthys flesus)

L. Marjorie, laboratory Mer, Molécule, Santé / Laboratory Mer, Molécule, Santé; A. Zalouk-Vergnoux, Univeristé de Nantes / MMS; C. Herrenknecht, University of Nantes / MMS EA; A. Kamari, University of Nantes / MMS; F. Yannick, University of Nantes / Laboratory of Toxicology; L. Poirier, Univeristé de Nantes / MMS

Rare Earth Elements (REEs) are a group of 17 metallic elements with close chemical and physical properties: scandium, yttrium and 14 lanthanides with atomic number ranging from 57 (La) to 71 (Lu). REEs are prevalently used in the industry sector indeed they are employed in numerous processes as in the production of supermagnet and luminophore, petroleum catalysis, pigmentation of plastics, metallurgical alloys, nuclear, MRI … The consumption of REEs was evaluated at 120 kt in 2014 and is increasing by 6% each year [1]. Hence these industrial uses are causing REE releases in the environment and particularly in aquatic ecosystems. REEs are becoming emergent contaminants but they are not yet taken into account in the current regulations. REEs are able to bioaccumulate in aquatic organisms and enter in the food chain. Indeed, REE bioaccumulation in aquatic organisms has already been observed in plankton, algae, bivalve, fish and turtles. REE bioaccumulation is worrying because these elements cause toxic effects. In fact, rare earth elements are neurotoxic, embryotoxic, cytotoxic and carcinogenic, moreover they can cause oxidative stress on cell. The Loire River (France) is one of the largest and the last wild river of west Europe. Its estuary from Saint-Nazaire up to Ancenis is characterized by an important anthropogenic pressure with potential REE emit activities as oil refinery, Aeronautic and naval industries, wind turbine industries, hospitals with MRI, coal-fired power plant … The aim of this study were to define REE bioaccumulation in muscles by eels and flounders, two key species of Loire estuary. They were selected because they have an important socio-economic weight, they are consumed by humans and they are benthic, thus living in contact with the sediment (preferential storage area for REEs). REE levels in eels were determined by ICP-MS at two stages of life (silver and yellow). The silver and yellow stages were distinguished by morphological and physiological changes. The adopted sampling strategy allowed to highlight potential spatio-temporal effects (breeding period and emission sources), intraspecific variations (age, sex, size and weight) and interspecific variations. The first results show that female silver eels accumulate significantly more than males for some TRs. They also show that TR concentrations in flounder muscles are significantly higher than in eel (yellow and silver) muscles.

208
Seasonal variability of metal and metalloid concentrations in blue mussels from the North and Baltic Seas

B. Knopf, IME Fraunhofer / Environmental Specimen Bank and Elemental Analysis; M. Paulus, Trier University; J. Koschorreck, Federal Environment Agency UBA; A. Fliedner, Fraunhofer IME Institute for Molecular Biology and Applied Ecology; H. Ruedel, Fraunhofer IME Institute for Molecular Biology and Applied Ecology / Department of Environmental Monitoring

Since the 1980s, blue mussels are sampled annually for the German Environmental Specimen Bank (ESB; www.umweltprobenbank.de/en). The samples are collected in two-monthly intervals at the North Sea sampling sites Eckwarderhörne and Königshafen and in six-month intervals at the Baltic Sea site Darßer Ort. The frozen mussel samples are cryo-milled to annual pooled samples for each sampling site. We investigated seasonal trends of metals/metalloids in the six-/ bimonthly sub-samples of the years 2013, 2015 and 2017. The objectives of this approach of this project should answer the following questions: 1) Are there any significant seasonal trends of the analytes investigated? 2) How does the seasonal variability compare to the concentration ranges covered by the temporal trends over the last decade(s)? 3) Is it possible to select one sampling period per year which would be representative for the annual mean value gathered from yearly pooled samples for future time trend analysis? In blue mussels at the North Sea site Königshafen we found consistent seasonal trends for cobalt, nickel, cadmium, copper and lead, as well as for selenium and arsenic for the years 2013 and 2015. However, in this trend was confirmed only for selenium in samples from 2017. The picture for mussels collected at the North Sea (Eckwarderhörne) was different: samples of 2013, 2015 and 2017 showed a consistent seasonality of exposure to metals/metalloids. In contrast, arsenic did not follow this trend. One remarkable result of our study is that the variability of element concentrations in the seasonal samples of one single year can be in the same order of magnitude as the concentration ranges over many years, i.e. the temporal trend, which is based on annual pool samples. A possible reason for the seasonal pattern can be the annual life cycle of the mussels. However, the concentrations of metals/metalloids in the mussel tissue are not only influenced by intrinsic biological factors but also by the concentrations of the elements in the surrounding water of the mussel. According to the concentration data found during the seasons it is not possible to determine one representative sampling point during the year which gives a comparable information as the annual pooled samples. It is therefore recommended to pool annual samples.

209
Sediment water interface release of 16 metal(loid)s under undisturbed and resuspension conditions in Trave Estuary sediments (German Baltic Coast)

H. Schröder, German Federal Institute of Hydrology / Division G-Qualitative Hydrology; D. Ecker, German Federal Institute of Hydrology BfG; T. Ternes, Bundesanstalt für Gewaesserkunde; L. Duester, German Federal Institute of Hydrology BfG

A study is presented that combines different approaches to estimate the risk posed by different Trave Estuary sediments (representative for the study area), which are in hotspots heavily polluted (especially exceeding guideline values for Cd, Pb and Zn) due to historical industrial use. For this purpose i) the dissolved concentrations of the 16 metal(oid)s Ag, As, Cd, Co, Cr, Cu, Fe, Mn, Mo, Ni, Pb, Sb, Se, Sn, V, Zn and the non-metals C, P and S in the pore water; ii) the binding form of the metal(loid)s in the solid phase and iii) the potential release of the analytes from sediment suspensions under different redox conditions are examined by i) *in-situ* and *ex-situ* pore water sampling using peeper and the recently introduced meso profiling and sampling system (*messy*); ii) sequential extraction following a modified BCR scheme; iii) suspension and manipulation of the sediments in the bio-geochemical microcosm and iv) simultaneous quantification of all analytes by ICP-QQQ-MS. Results show that i) metal(loid)s in contaminated and uncontaminated sediments of the study area are similarly partitioned between the different fractions of the BCR scheme; ii) dissolved concentrations in the pore water are very similar in the different sediments and vary significantly only in the first cm below the SWI; iii) comparable dissolved concentrations and concentration gradients can be obtained by dialyses based i*n-situ* sampling and suction based sampling from undisturbed sediment cores in the lab; iv) many metal(loid)s are released in case of resuspension, with increasing amounts of elements preferentially bound in the non-residual fractions being released at high redox potentials; v) the expected release of all metal(loid)s is low compared to the overall load of the river Trave; and vi) most pristine, fine-grained sediments of the study area pose the highest risk of metal(loid) release in case of sediment re-suspension.

Substitution of Chemicals of Concern: Perspectives and Connections between Analysis of Alternatives, Sustainable Chemistry and Safe-by-design (I)

210
Latest developments in the science and practice of alternatives assessment and further research needs

M. Jacobs, University of Massachusetts, Lowell / Lowell Center for Sustainable Production; J.A. Tickner, University of Massachusetts, Lowell / Community Health and Sustainability; R. Simon, University of Massachusetts, Lowell; S. Edwards, University of Massachusetts Lowell / Lowell Center for Sustainable Production

Alternatives assessment (also known as analysis of alternatives) emerged nearly two decades ago to help guide the evaluation and adoption of safer and feasible substitutes for hazardous chemicals of concern. Today, alternatives assessment is being used in a range of substitution and safer chemistry development contexts, including industry chemicals management operations, regulatory programs, procurement activities, voluntary government substitution support programs, among others. Although the general alternatives assessment frameworks used among these different stakeholders address similar process components of an alternatives assessment, there is a recognition within the field that specific methods and tools used in any given assessment need to be flexible, iterative and adaptable as the specific decision contexts widely vary. Academia, consulting firms, non-governmental organizations (NGOs) and government authorities have contributed tremendously over the last five years to the development of new methods and tools to assist with the alternatives assessment process, recognizing this “fit for purpose” need. New developments in the use of methods to assess the intrinsic exposure potential of a given alternative and the consideration of broader life cycle considerations will be described. New resources and tools for addressing data gaps in the hazard assessment component of the assessment will be shared as well as insights from recent decision analysis/decision making research. Key needs to advance the methods and practice of alternatives assessment as elevated during the recent 2018 *International Symposium on Alternatives Assessment* and as outlined in a recent research and practice agenda for the field will be reviewed.

Case studies on Analysis of Alternatives under the REACH Authorisation process

E. Van Asbroeck, Apeiron-team NV

In this session we will discuss several examples of Analysis of Alternatives for substances of concern for a specific use. Starting from the key functional requirements of the substance and the required performance it delivers in the end-product, leads to a range of potential alternatives to be objectively assessed against clear decision criteria, to arrive at the final substitution choice. Potential alternatives include: (i) drop-in alternative, (ii) alternative technology, (iii) alternative end-product, but also (iv) relocation and (v) stopping the business. We apply a two-step approach. In the first step, alternatives are looked for as broadly as possible, including; by evaluating the reasons of failure of alternatives tested in the past, by checking what competitors are doing, by cross sector assessment of technologies, by inspiration gathered at green chemistry conferences, etc. In the second step, the short listed highest potential alternatives are assessed in detail on the four criteria defined by REACH in the Authorisation process: (i) reduction of risk, (ii) technical feasibility, (iii) availability and (iv) economic feasibility. The case studies demonstrate how the methodology of Analysis of Alternatives under the REACH Authorisation process can be used as a tool to enable substitution, leading to added value for society while avoiding regrettable substitution.

Substitution of Hazardous Chemicals: Lessons, Opportunities and Challenges from a Civil Society Organization's Perspective
M. Wang, D. Santillo, K. Brigden, Greenpeace Research Laboratories
Substitution is a vital element of approaches to address hazardous chemicals and wastes. Support for development and implementation of, and further innovation in, environmentally sound and safer alternatives (including clean production, informed substitution of chemicals of particular concern, non-chemical alternatives) is one of the risk reduction objectives of the Strategic Approach To International Chemicals Management (SAICM), as well as a strategic pathway to the overarching EU objectives for a non-toxic environment. Success in practice depends on the collaborative efforts of all relevant stakeholders, each with a unique role to play. In this SETAC-ECHA substitution special session, we will provide thoughts and relevant experience from a civil society organization perspective, on the following topics, in order to contribute to further discussions: - Drivers for substitution - Importance of collaboration among stakeholders - The role of civil societies in substitution and the importance of their technical and professional capability. - The importance and role of supply chain evaluation and management - Information availability and commercial confidentiality: challenges and opportunities - Functional substitution - chemical and non-chemical alternatives: awareness, guidance, assessment and supporting instrument

Wildlife Ecotoxicology: From Sub-lethal Responses to Adverse Effects at Individual and Population Level

217
Immunomodulative effects of trace metals in small mammals models
D. García-Mendoza, Wageningen University & Research / Toxicology; B. Han, H.H. van den Berg, Wageningen University & Research / Division of Toxicology; N. van den Brink, Wageningen University / Dept of Toxicology
The effect assessment of immunotoxic contaminants, e.g. trace metals, in environmentally exposed animals is relevant particularly in wildlife species of small mammals that act as hosts for zoonotic infectious agents and modulation of their immune system could play a role in the transmission of such infections. Using a bottom up strategy we assessed the effect of cadmium, a known widespread contaminant metal with immunotoxic potential, on the murine immune system. Initially, we performed an *in vitro* study using different murine immune cell lines showing that cadmium is cytotoxic and may cause toxic and functional effects in different immune cell types, at sub-cytotoxic concentrations. Innate immune cell models, macrophages (RAW264.7 and NR8383 cell lines) and mast cells (MC/9 and RBL-2H3 cell lines), showed a dose dependent depletion of cellular glutathione; while in cells from the adaptive immune system, T lymphocytes (D10.G4.1 cell line) and B lymphocytes (CW13.20-3B3 cell line), glutathione levels were low and cadmium did not have an effect. In all cell lines tested apoptosis was induced at high cadmium concentrations just below cytotoxic levels. Functional effects also showed differential effects. While in activated macrophages cadmium increased pro-inflammatory effects, by enhancing the production of TNFα and nitrite, opposite effects were observed in mast cells, by decreasing the production of TNFα and histamine. In the T cell (Th2) model, proliferation and production of IL-4 cytokine was increased in activated cells at low cadmium concentrations. At sub-cytotoxic concentrations cadmium did not have significant functional effects on the B cell model in study. In order to increase the level of immune integration, ongoing research will determine the effect of cadmium on the T cell-dependent antibody response using *in vivo* mouse models. The evaluation of such response, described as the best predictor for immunosuppression, is dependent on the activation and communication of different immune cell types, which are differentially susceptible of being affected by the exposure to immunotoxicants. The comparison and correlation of *in vitro* and *in vivo* studies will give insight on the potential effects of the environmental exposure to immunotoxic contaminants, such as cadmium, in the immunity of small mammal species, as well as to provide the most relevant *in vitro* endpoints for immunotoxicological assessment.

218
Organic pollutants, rodenticides and metalls in the urban terrestrial ecosystem; the case study Oslo city
D. Herzke, NILU - Norwegian Institute for Air Research / FRAM Centre Tromso; E.S. Heimstad, NILU - Norwegian Institute for Air Research; T. Nygård, Norwegian Institute for Nature Research NINA
Persistent organic pollutants (POPs), perfluorinated alkylated substances (PFAS), siloxanes, chlorinated paraffins, organic phosphoric flame retardants (OPFR), dechloranes, UV filters, rodenticides and heavy metals were measured in the terrestrial urban environment of the city of Oslo, Norway, since 2014. NILU and NINA investigated a terrestrial food chain supplemented by predatory species covering varying feeding behaviours (air, soil, earthworm, eggs from fieldfare, sparrowhawk and tawny owl and in liver of red fox, brown rats and batchers). In general, we found a variety of the investigated pollutants in all matrices, with even being able to point out so far unknown pointsources of pollution within the city. Elevated PFAS concentrations in soil and earthworms were found in locations used for skiing activities as well as industrial activities. In 2016, Bromodiolone and brodifacoum were found in rat- and foxlivers varying between up to 3883 ng/g ww and up to 1072 ng/g ww, respectively. We observed major differences between the concentrations and patterns of accumulation of organic pollutants and metals between the species involved in this study. Levels of organic pollutants, especially PCBs, are much higher in the top predators (eggs of sparrowhawk) than in the other species. On the other hand, metals were much higher in earthworms than in any other species. In terms of quantity, PFAS were present in most of the investigated sample types. Distinct interspecies differences were found. PFOS is the overall dominating compound. PFDoA, PFTriA and PFTeA contribute more higher up in the food-chains (fieldfare, sparrowhawk and tawny owl), but also in rodents. Emerging PFAS were also detected. SCCPs were present in all air, soil, fox, sparrowhawk and tawny owl samples, indicating an ubiquitous distribution in Oslo. MCCPs were only found sporadically, mostly in earthworms and soil. In 2016, besides elevated concentrations in air (average 1533 ng/sampler, we detected the highest sumSiloxane concentrations in eggs of sparrowhawk (11.3 ng/g lw) followed by worms and tawny owl eggs (9.9 and 3.1 ng/g lw). OPFRs were either not detectable, or were found in very low levels at the higher trophic levels in biota. However, in earthworms appreciable levels were found (SumOPFR of 898 ng/g lw), compared to about 10 ng/g lw in sparrowhawk, tawny owl and rat liver, all data from 2016. Based on our findings, the trophic magnification potential of these compounds seems to be low.

219
Assessing exposure and toxicity of anticoagulant rodenticides to birds of prey in British Columbia, Canada
J.E. Elliott, Environment and Climate Change Canada / Science and Technology Branch Ecotoxicology and Wildlife Health Division; V. Silverthorn, Saltspring Island; S. Lee, Environment and Climate Change Canada; S. Hindmarch, Fraser Valley Conservancy; V. Bowes, Britsh Columbia Ministry of Agriculture; F. Maisonneuve, Environment and Climate Change Canada
Anticoagulant rodenticides dominate pest rodent control globally. Second generation anticoagulants (SGARs) are persistent, bioaccumulative and toxic chemicals that have become widespread contaminants of terrestrial birds of prey. We present data on concentrations of anticoagulants and autopsy results for 560 raptorial birds found dead or brought into rehab, 1988-2016 in British Columbia. Larger generalist owls, e.g. barred owl (*Strix varia*) and great-horned owl (*Bubo virginianus*), had the greatest incidence of exposure; smaller owls e.g. barn owl (*Tyto alba*) had lower incidence , as did hawks, e.g. red-tailed hawk (*Buteo jamaicensis*) and Cooper's Hawk. Bird eating merlins (*Falco Columbarius*) had lowest incidence of exposure among diurnal raptors. Modeling of autopsy and liver residue data show barn owls to be the most sensitive to SGAR poisoning, while great-horned owl least. Probability of lethal AR poisoning increased above 0.1 ug/g SGAR in liver, and rapidly above 0.5 ug/g. Over the study period, the incidence of exposure to SGARs increased from 1988 onwards, remaining consistently high (above 75%) from 2003- 2009, then declining from 2009-2016, which coincides with introduction of regulatory measures in Canada to reduce usage of the most toxic SGARs. Vehicle collision was the most common cause of death for all raptors, followed by trauma, undetermined cause, emaciation, and AR poisoning, which was more common than window collision.

220
Multiple stressors affect bird health: a case study in lead contaminated environments
J. Lidman, Department of biology and environmental science, Umeå university / Department of Ecology and Environmental Science; M. Jonsson, Umea University; . Berglund, Umea University / Ecology and Environmental Science
Birds have long been used as biomonitoring species in contaminated environments and although we have good knowledge on the toxic effects of single compounds from laboratory experiments, the outcome may differ in the field, due to multiple stressors in a natural setting. Also, even one single stressor might have multiple effects on the same target due to direct and indirect pathways. In this study we assessed multiple effects of mining activities on insectivorous birds (*Ficedula hypoleuca*) using hemoglobin (Hb) levels as an indicator for bird health. We used metal accumulation (both essential and non-essential), habitat type, and food availability to explore direct and indirect effects of mining. Contrary to our expectation, Hb levels were not directly related with lead exposure, even though lead is known to affect heme synthesis and lead concentration in birds from the mining area exceeded the suggested threshold for lead toxicity. Instead availability of terrestrial flying insects, connection to water and distance to the mine were more important, indicating that the indirect effects of mining activities and specific food items, in addition to habitat, play an important role in the overall bird health. This study highlight the importance of including multiple co-occur stressors when assessing responses of contaminants in wildlife.

221
Parental foraging strategies, mercury load and offspring quality in a coastal breeding gull species
C.S. Santos, Ghent University (UGent) / Terrestrial Ecology Unit (TEREC) - Department of Biology; A. Sotillo, University of Aveiro / Department of Biology; M. Monteiro, Aveiro University / Biology; L. Lens, Ghent University / Terrestrial Ecology Unit Biology Department; S. Loureiro, Universidade de Aveiro / Biology
Mercury (Hg) contamination is known to trigger a wide range of deleterious effects on free-ranging animal populations. Monitoring Hg exposure and effects of Hg in sentinel species such as seabirds is hence important to evaluate Hg risks at the population and ecosystem level. This study aimed to address this topic by studying the implications of parental foraging strategies on the Hg input in eggs and chicks, and how this input connects with offspring development, physiological condition and behaviour in the generalist Lesser Black-backed gull (*Larus fuscus*). To address this, a series of field studies were performed, as well as an experimental study carried out at an aviary facility. Briefly, a population of *L. fuscus* was monitored in Zeebrugge (Belgium, 51º2'N, 03º11'E) between 2012-2015. Eggs and chicks' down feathers and primary feathers were collected to assess their main dietary origin and quality, by determining isotopic signatures of carbon (δ13C) and nitrogen (δ15N), and total Hg burden. Parental input of Hg in offspring quality was then assessed by relating information on parental foraging strategies and Hg load with clutch volume and proxies of chick health (e.g. growth rate, body condition and physiological state). Moreover, in a controlled dietary experiment, carried out at an aviary facility, chicks' body condition, physiological state and behaviour (e.g. begging behaviour) was assessed and related to Hg burden of chicks accumulated via dietary uptake. As expected, eggs and chicks' feathers from parents with a stable isotope signature that suggested a predominantly marine diet had higher levels of Hg. Increased maternal input of Hg by females during egg-formation period was negatively related with maternal investment in clutch volume and positively related with Hg load in newly hatched chicks. The latter, in turn, tended to be positively related to DNA damage and negatively related to body condition of chicks. Moreover, increased input of Hg during post-hatch period was associated with a decrease in early development and physiological condition of the chicks. Taken together, our results suggest that the use of marine sources increased maternal and parental input of Hg which may have negative effects on offspring quality.

Aquatic and Terrestrial Plant Ecology: Ecotoxicology, Risk Assessment and Modelling (I)

223
Assessing herbicide effects on non-target terrestrial plants in the greenhouse and in the field
R.J. Isemer-Kellner, Bayer Ag / Environmental Safety Ecotoxicology; C. Mihan, D. Jans, V. Ducrot, Bayer AG Crop Science Division / Environmental Safety Ecotoxicology
During the regulatory approval process for herbicides, potential side-effects to non-target terrestrial plants (NTTP) are evaluated. Routine testing in form of standardized lower tier greenhouse studies is used to assess potential risks. Higher tier testing approaches like field studies may be needed to assess whether the identified risks may occur under more realistic conditions in the field. So far no agreed NTTP field study method has been established. We developed a method for conducting higher tier field studies with NTTPs (posters SETAC Europe 2016&2017, presentation SETAC US 2018) and compared the results to standard greenhouse testing. Effects of a sulfonyl-urea herbicide on 10 crop species as surrogates for NTTPs were measured in the greenhouse in a standard dose-response test according to OECD Guideline 227 (Terrestrial Plant Test: Vegetative Vigour Test, 2006). Shoot dry weight of sugar beet was shown to be the most sensitive endpoint. Lower tier studies in environmentally controlled greenhouses are designed to minimize variation in order to allow for a statistically reliable detection of effects. On the down side, these artificial growth conditions tend to overestimate effects of herbicides due to lack of realism. The higher tier NTTP field study method we have developed may be suitable to overcome this gap. Throughout the growing season 2017 (May to September), the same herbicide already used in the greenhouse testing was tested on 11 plant species sown as a seed mixture for establishing artificial plant communities on a test acre in Germany. Three herbicide rates similar to those used in the greenhouse testing were applied. Vegetation cover according to the Londo scale, dry biomass of total vegetation, symptoms of phytotoxicity as well as BBCH stage of the sown species were assessed. The assessed endpoints and species showed different responses to the tested herbicide and variability was high for some endpoints. Community level metrics such as principal response curves cover endpoints for single species and may be most suitable for the risk assessment. Effects of the herbicide under field conditions were less pronounced than predicted by the corresponding greenhouse study confirming the suitability of the proposed field study method for refining the risk assessment for NTTPs. It needs to be discussed carefully, how to deal with higher variability as well as which of the endpoints should be integrated into the future risk assessment.

224
Viability and reliability of assessing reproductive traits of non-crop species for risk assessment under greenhouse conditions
A. Duffner, Eurofins Agroscience Services Ecotox GmbH / Terrestrial Ecotoxicology Lab; C. Gimeno, Trialcamp S.L.U.; T. Moser, Eurofins Agroscience Services Ecotox GmbH
Agriculture is the dominating land-use of the EU member states by covering nearly half of the surface area. Using herbicides to reduce weed competition in agricultural areas can adversely affect non-target terrestrial plants (NTTP's) growing at field margins which provide broad spectrum of ecosystem services (MEA 2005). According to the recent EFSA Opinion for NTTP's (2014) one important goal is maintaining the biodiversity of plant species in the agricultural area. It is therefore recommended to include also non-crop species in the testing scheme from the list provided in OECD guidelines (OECD 208 and 227) and to assess reproductive endpoints such as e.g. seed production. The general objective of this work was to assess the viability and reliability of generative traits of non-crop species for risk assessment under greenhouse conditions in two different European zones. Two different experimental setups were tested. Setup 1: For crops and non-crop-species biomass and plant height at the vegetative and generative growing stage and seed production was assessed when growing at 5 different plant densities in untreated soil, respectively. Setup 2: Selected crop and non-crop species from setup 1 growing at a selected plant density were treated with a total herbicide at five non-lethal application rates. Biomass at the vegetative and generative growing stage and seed production was assessed. The non-crop species for both setups were chosen from the appendix of the OECD guidelines 208 and 227. In both setups 6 replicates were used for each treatment. Both setups were conducted in two greenhouses in different European zones (Germany and Spain). In both setups the biomass and seed production will be statistically evaluated and the coefficients of variation for biomass (vegetative vs. generative growing stage) and seed production will be compared between crops and non-crop species. For setup 2 the ER_X values will additionally be presented for biomass and seed production, where possible. References: EFSA PPR Panel (2014): Scientific Opinion addressing the state of the science on risk assessment of plant protection products for non-target terrestrial plants. 225
Novel methodology for evaluating the ecological impacts of environmentally relevant antibiotic mixtures on agricultural landscapes
J.B. Sallach, University of York / Environment; S. Toet, J. Stockdale, University of York; A. Zealand, Newcastle University; D.W. Graham, Newcastle University / School of Civil Engineering and Geosciences; A. Boxall, University of York / Environment and Geography Department
Fresh water resources are under stress as a result of increasing global populations and a changing climate. As a result, the reuse of wastewater has become a valuable alternative to meet agricultural irrigation demands. However, wastewater effluent is a known reservoir for pharmaceutical residues which include potentially dozens of antibiotic compounds. The impacts of antibiotic exposure in

the agro-ecosystem is of particular concern due to the bio-activity of these compounds and key role microbes play in soil-plant systems. Here we use an exposure algorithm to determine a mixture of antibiotics and predicted environmental concentrations (PECs) in wastewater effluents based on prescription data from the United Kingdom. A synthetic wastewater was prepared and spiked at 5 treatment levels (Control, PEC/10, PEC, 10xPEC, & 100xPEC) and used to irrigate spring barley over a full growth cycle (approximately 12 weeks). Over that period, soil samples were collected at various time periods (prior to antibiotic exposure, 16 hours after initial exposure, 6 weeks of exposure, and 12 weeks of exposure) to track changes in microbial community structure and changes in antimicrobial gene expression. Plant growth parameters were evaluated throughout the study including plant density, tiller formation, leaf development, and plant height. Plant density was negatively correlated with antibiotic exposure with a dose dependent response and this difference increased throughout the growth season. The Skygas 2D system, developed at the University of York, was deployed throughout the entire experiment to continuously measure net ecosystem exchange (NEE) of greenhouse gasses including CO_2, N_2O, and methane. Results showed, for example, that significant differences in NEE of CO_2 corresponded with increased antibiotic exposure as the plants matured. Analytical techniques including targeted LC-MS/MS used to track the fate of antibiotics in the soil-plant system, high mass accuracy LC-MS/MS to evaluate changes in the extractable plant metabolome, and GC-MSD for stable isotope analysis were employed. Results of this study show that at environmentally relevant concentrations, a mixture of antibiotics can impact the soil-barley system and alter ecosystem function.

226
Effects of pesticide mixtures on algal biofilm structure and function
M. Bighiu, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; W. Goedkoop, Swedish University of Agri Sciences / Department of Aquatic Sciences and Assessment
Agricultural pesticides may reach surface waters and impact non-target aquatic organisms and key ecosystem functions. Algal biofilms are ubiquitous in aquatic environments, form the base of aquatic food webs, and have an important role in nutrient and carbon cycling. We investigated the effects of pesticide mixtures on the function (i.e., photosynthetic efficiency) and structure (i.e., taxa composition) of algal biofilms, as well as their recovery after exposure, in a laboratory experiment. Pesticides found in the highest concentrations in Swedish streams were selected for laboratory tests (i.e., 6 herbicides and 1 fungicide). Three mixtures containing 3 pesticides with different modes of action were used in a dilution series ranging from observed toxic units (TU) in long-term monitoring samples, i.e. 1xTU to 100xTU. We found a decrease in biofilm photosynthetic efficiency at concentrations > 10xTU. However, in the low exposures we also observed a stimulatory effect on biofilm photosynthetic efficiency after 2 days of exposure. The latter was interpreted as an increased chlorophyll a production in response to stress, also known as the 'greening effect'. The recovery of the photosynthetic efficiency was high (i.e., 97% of the treatments), especially for biofilms that had experienced low pesticide exposures. This recovery suggests that the pesticides caused a temporary downregulation of photosystem II, but not a permanent damage. However, as our TUs are based on weekly average concentrations measured in the field, it is important to consider that peaks might occur during shorter time intervals, thus leading to potentially higher exposure *in situ*. Preliminary results on biofilm assemblage composition show that several taxa were present only in the control treatments (i.e., the green algae *Aphanochaete* and *Closterium* and the cyanobacteria *Lyngbya* and *Pseudanabaena*). This suggests that pesticides act as a selective pressure for tolerant taxa and can alter natural algal assemblages in biofilms.

227
Assessment of biomarkers in macrophytes exposed to individual and combined pollutants of agricultural run-off and climate change
V. Vijayaraj, M. Laviale, Universite de Lorraine; S. Hilt, Leibniz Institute of Freshwater Ecology and Inland Fisheries / Ecosystem Research Division; J. Leflaive, Université de Toulouse; M. Schmitt-Jansen, Helmholz Centre for Environmental Research-UFZ / Bioanalytical Ecotoxicology; J. Allen, Université de Toulouse / ECOLAB UMR CNRS 5245; N. Kipferler, Ludwig-Maximilians-University Munich / Department of Biology; B.H. Polst, Helmholtz centre for environmental research - UFZ / Department of Bioanalytical Ecotoxicology; E.M. Gross, University of Lorraine / Laboratoire Interdisciplinaire des Ecosystemes Continentaux
Macrophytes play an important role in nutrient cycling and in physical and community structuring of aquatic ecosystems. Their potential susceptibility to environmental stressors could therefore lead to a disruption of biotic and abiotic interactions in shallow aquatic systems. In addition to endpoints such as growth and mortality, we consider it important to determine a so-called stressor-specific "chemical fingerprint" of the plant species. Eurasian watermilfoil, *Myriophyllum spicatum* (an OECD as a test organism), the pondweed *Potamogeton perfoliatus* and the waterweed *Elodea nuttallii* have been used in our study to determine individual and combined effects of agricultural run-off (ARO, a defined mixture of nitrates, copper and pesticides) and climate warming. Plants from different microcosm experiments testing effects of different concentrations and pulses of an ARO cocktail at ambient and elevated (+4°C) temperature were analysed. Plant biomass and biomarkers such as pigments, anthocyanins, total phenols and elemental stoichiometry were analysed. *E. nuttallii* showed reduced biomass yield at both ambient and elevated temperature (+4°C) in the presence of ARO. All plants showed a more or less distinct change in pigment patterns, with a tendency of increased chlorophyll contents. A significant increase in carotenoids was seen in *E. nuttallii* at elevated temperature. For *M. spicatum*, a significant reduction in polyphenols was seen at the highest ARO concentration at elevated temperature. In our study, we expect an effect of temperature and ARO on different submerged macrophytes, and that the individual and combined stressor-effects would be better seen with our chemical and physiological biomarkers than by just analysing growth parameters.

Aquatic Plant Exposures - The Complexities of Higher Tier Testing
A. Kirkwood, C. Hedderig, Smithers Viscient LLC / Ecotoxicology; C.R. Picard, Smithers Viscient, LLC / Terrestrial Ecotoxicology; J. Hoberg, Smithers Viscient LLC / Ecotoxicology; R.C. Biever, Smithers Viscient, LLC / Department of Ecotoxicology; J. Schwalbe, Smithers Viscient, LLC
Toxicity testing with aquatic macrophytes is a valuable tool in assessing the risk of herbicides to aquatic plants, particularly for instances where *Lemna* spp. may not provide a complete representation of risk for a specific compound. These aquatic plant tests, however, come with a unique set of challenges. One of the main challenges is determining appropriate species to use when designing exposure(s) when the goal is to produce a species sensitivity distribution (SSD). There are several aspects to consider, including whether there is a published guideline or test method for the species, if there are defined endpoints and acceptability criteria, and if the plants are readily available from reputable suppliers. Guidance for laboratory testing of *Myriophyllum spicatum* exists in OECD TG 239. Published literature on the use of alternate species for laboratory or outdoor environmental testing is available, but no formal, validated test methods for these species exist. Therefore, modifications to the OECD TG 239 exposure design are often implemented when alternate species are utilized in a similar single-species laboratory format. However, the parameters referenced in the OECD TG 239 guidance may not represent the ideal conditions for adequate plant growth resulting in an overall data set that does not properly assess potential toxicity. When determining environmental risk for herbicides, there is a progression of testing tiers for aquatic plants, and each tier has associated benefits and challenges which help to determine what kind of testing should be designed for the goals and objectives. Caution should be used when applying acceptability criteria set for *M. spicatum* to alternate species in single species exposures, as there are currently no validated methods for the alternate species. In order for alternative species to meet similar criteria, some modifications may be required to the amount or source of nutrients in the sediment, temperature or lighting ranges, or culturing practices. With regards to longer-term multi-species studies, as there is no specific guidance for the conduct of the study or required criteria, each exposure system needs to be carefully designed based on the intended objectives. Therefore, test duration, exposure duration, number of species required, and monitoring and sampling intervals will potentially vary between studies.

Complex Mixtures in the Environment: Monitoring, Fingerprinting and Assessment (I)

229
How do ion mobility and collision cross section benefit non-target identification in environmental studies
C. Gallampois, Umea University / Chemistry; P. Ojeda May, Umea University / High Performance Computing Centre North; P. Haglund, Umea University / Department of Chemistry
The identification of chemicals in complex mixtures, such as environmental samples is a challenge due to the presence of both natural and man-made compounds, at different level of concentrations. Separation is a key word to be able to detect low concentration chemicals in such mixtures. Ion mobility (IM) coupled to liquid chromatography (LC) and mass spectrometry (MS) is able to separate isomers and to provide an extra physical chemical parameter, the cross collision section (CCS). The set of isomers, tris(1-chloropropyl) phosphate, tris(2-chloropropyl) phosphate and tris(3-chloropropyl) phosphate presented different CCS values, 161.8, 162.1 and 162.5 Å^2, respectively (measured in nitrogen gas). The lowest difference was about 0.2% between the tris(1-chloropropyl) phosphate and tris(2-chloropropyl) phosphate. Thus, even with a low difference of CCS value we are able to make the difference between two isomers based only on this value. A CCS prediction model was developed using a stochastic Projection Approximation method (Monte Carlo simulations). The training set contains 19 pharmaceuticals and pesticides. The first results showed error between 0.3% to 4.1% for most of the compounds (e.g. mirtazapine and cycluron, respectively), 3 compounds had an error around 8% (e.g. tramadol) and the last three compounds had a much larger error, between 18% and 25% (azithromycin and bisoprolol, respectively). These results showed the importance of considering electrostatic

effects in the model. Environmental samples (e.g. sludge, influent or effluent waters) will be considered to verify the applicability of CCS values, but also to know to which extend these values can be of help the non-target identification workflows.

230
Comparing mass, retention time and MS2 spectra as criteria for the automated screening of small molecules in aqueous environmental samples analysed by LC-QToF-MS/MS
K. Jewell, German Federal Institute of Hydrology; C. Dietrich, B. Ehlig, F. Thron, A. Wick, Federal Institute of Hydrology; T. Ternes, Bundesanstalt für Gewaesserkunde
The adoption of database screening using high-resolution, LC-MS data is promising as a pre-screening and routine monitoring tool but depends on the ability to perform reliable data processing on a large number of samples in a unified workflow. Strategies to minimize errors have been proposed but automated procedures are rare. High-resolution LC–ESI-QToF-MS/MS was performed for the analysis of aqueous samples by direct injection. Data processing was achieved with software tools written in *R*. A database containing MS^2 spectra of 693 compounds was integrated into the workflow. Standard mixes and a series of 361 samples of river water were analyzed and processed with the optimized workflow. Using the database and a mix of 70 standards for testing, it was found that an identification strategy including i) mass ii) retention time and iii) MS^2 spectral matching achieved a 2- to 3-fold improvement in the fraction of false positives compared to using only two criteria, while the number of false negatives remained low. The optimized workflow was applied to the sample series of river water. In total, 149 compounds were identified. The best strategy for a database screening approach with minimal manual data manipulation is focused on the reduction of false positives, allowing for the screening of hundreds of water samples for hundreds of compounds in a single run.

231
Risk-based prioritisation of organic micropollutants in WWTP effluents and surface waters on a European scale
W. Brack, T. Schulze, Helmholtz centre for environmental research - UFZ / Effect-Directed Analysis; L. Beckers, Helmholtz-Zentrum für Umweltforschung GmbH - UFZ / Effect-Directed Analysis; E. Müller, M. Krauss, Helmholtz centre for environmental research - UFZ / Effect-Directed Analysis
The EU project SOLUTIONS provided a huge set of LC-HRMS screening data recorded in a harmonized way at about 500 sites all over Europe including the large rivers Rhine and Danube, a lot of small rivers in many different European countries, rain-event-based samples from small agricultural streams, seasonal series of water samples and a large number of wastewater treatment plant (WWTP) effluents from all over Europe. In the present study these samples were assessed for about 1000 organic micropollutants and their contribution to the overall risk for the three Biological Quality Elements (BQEs) algae, macroinvertebrates and fish. Frequently occurring risk drivers and mixtures thereof were identified. Differences and similarities between large and small rivers, different geographical regions, rain-event and base-flow samples have been evaluated. The criteria for target compound selection were (1) previous detection in surface waters or (2) prediction by emission-based modelling to occur at substantial concentrations in European surface waters or to substantially contribute to risks on aquatic ecosystems. In WWTP effluents more than 300 chemicals have been detected and assessed using the Toxic Unit (TU) approach. Particularly for invertebrates, åTUs exceeded 1 in many effluents with up to 5-fold exceedance in some effluents dominated by specific insecticides. For algae and fish in most cases åTU is between 0.1 and 1, which still represents significant risks. Although the assessment revealed a certain degree of site-specificity for the different types of samples, consistent mixtures of risk drivers became obvious. Taking WWTP effluents as an example, risks to algae during the application period in spring were dominated by photosynthesis inhibitors, while outside this time antibiotics and other pharmaceuticals become dominating, which are emitted the whole year.

232
Occurrence and distribution of organic micropollutants in water, sediments and snail tissues in freshwater systems of western Kenya
F. Kandie, Helmholtz Centre for Environmental Research UFZ; A. Ganatra, International Center for Insect Physiology and Ecology; M. Krauss, Helmholtz centre for environmental research - UFZ / Effect-Directed Analysis; B. Torto, Internation center for insect physiology and ecology; W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect-Directed Analysis
In the last decades, the uncontrolled use of emerging organic micropollutants including pharmaceutically active compounds (PhACs), pesticides and industrial chemicals led to their increased detection in the environment. Increasing consumption and discharge has led to concerns on the (eco)toxicological effects since these compounds have been shown to cause adverse effects on organisms including acute and chronic toxicity and endocrine disruption even at low concentrations. Monitoring of these compounds has led to detections in various matrices, with concentrations ranging from sub-ng L^{-1} to $\mu g\ L^{-1}$. However, most of these studies have been performed in developed countries with limited information from developing countries. Since chemical monitoring data are hardly available for Kenyan surface waters, the main objective was to determine the multi-compartment occurrence of chemical mixtures in freshwater systems. Specifically, we aim to: 1) identify and quantify organic micropollutants present within the water, sediments and snail phases, 2) determine the chemical activity and toxic units of these pollutants and 3) for the first time, report the occurrence of personal care products and metabolites in Kenya. Forty eight sites were selected for the monitoring of pesticides, PhACs, hormones, preservatives and their metabolites. To access the impact of land use, different sites were sampled including 27 agricultural (maize, sugarcane, rice and tea), 8 urban and 13 natural sites (potentially no anthropogenic influence). Out of the 580 target compounds, 188 and 64 compounds were detected in water and snails, respectively. In snails, oxypurinol showed the highest concentrations (up to 3.3 $\mu g\ g^{-1}$ snail) while acetyl-sulfamethoxazole (up to 23 $\mu g\ L^{-1}$) was detected mostly in the water samples. Acetyl-sulfamethoxazole is a metabolite of sulfamethoxazole which is used to treat several bacterial infections. The snails showed the capacity to act as passive samplers of the contaminants therefore giving a holistic view of chemical status in aquatic ecosystem as compared to grab samples which are time dependent. Further steps will involve evaluation of sediment data, determination of chemical activities, toxic units calculation and pattern analysis. The results of this study will shed light on the occurrence levels and toxicities of the pollutants present within the aquatic system in western Kenya.

233
Bioassay-based profiling of steroid- and dioxin-like activities in French river waters using grab and integrative sampling
C. Chardon, INERIS; E. Maillot-Maréchal, INERIS / UMRI SEBIO ECOT; B. Piccini, INERIS; A. Daval, C. Miège, Irstea Lyon; E. Noël-Chéry, C. Tixier, I. Allan, IFREMER; F. Brion, INERIS / Ecotoxicology Unit; S. Ait-Aissa, INERIS / UMRI SEBIO ECOT
Effect-based methods (EBM) are relevant tools to monitor chemical quality of aquatic systems as they provide integrative assessment of contamination components and inform on hazard associated with complex mixtures. In the frame of a French national program aiming at demonstrating the operational performance of passive sampling to monitor priority chemicals in surface waters, we applied a panel of *in vitro* bioassays to investigate 1) the occurrence of steroid- and dioxin-/PAH-like activities, 2) their distribution in the water column using grab sampling and integrative passive sampling. In addition, we looked into the relevance of *in vitro* estrogenicity in the water as compared to established trigger values and *in vivo* assessment in zebrafish. Twenty surface water sites of different anthropogenic pressures were studied. For each of them, both grab (dissolved phase and particulate matter) and integrative sampling (POCIS and Silicone Rubber membranes) were performed over a 15 days period and organic extract of each sample was analyzed with the bioassays. *In vitro* toxicity profiles in grab water organic extracts showed contrasted contamination patterns depending on the time of sampling (T0 and T15) and the studied sites. Estrogenic and PAH-like activities were the most occurent activities, while glucocorticoidic and anti-androgenic ones were detected at specific sites. No androgenic activity was detected. PAH-like activity was associated with both the dissolved and particulate matter phases while endocrine activities were only found in the dissolved phase. At some sites, *in vitro* estradiol-equivalents were found above the generic trigger value considering environmental risk (0.4 ng E2Eq/L). For 7 sites out of the 10 tested *in vivo*, activities were coherent with those predicted by *in vitro* bioassays. The present study highlights the relevance of combining a set of effect-based tools and smart sampling to monitor site-specific contamination of surface water chemical quality and the partitioning of measured activities in the water column. Our approach further includes *in vivo* mechanism-based assays, which enhances the toxicological relevance of the assessment. Comparison of our data with established trigger values for some activities will be discussed. Finally, ongoing chemical analyses of more than 100 priority substances, including estrogenic hormones, will allow the determination of their contribution to the biological activities detected.

234
Antibiotics screening assay: strain selection for validation and application to environmental samples
T. Jonkers, VU University / Environment & Health; L. Schalkwijk, Vrije Universiteit Amsterdam / Environment & Health; J. Luirink, D. Bald, Vrije Universiteit Amsterdam; C.J. Houtman, The Water Laboratory; J. Kool, Vrije Universiteit Amsterdam / Biomolecular Analysis and Spectroscopy; M. Lamoree, T. Hamers, Vrije Universiteit Amsterdam / Environment & Health
Chemicals of emerging concern (CECs) are mostly water-soluble chemicals that have just been or are yet to be identified as contaminants, and are often not included in routine monitoring programs. Toxicological and physicochemical data of these substances are usually lacking, complicating risk assessments for environmental and human health. The identification and risk characterization of CECs may indicate the need for new or additional regulation. Antibiotics are CECs as they are pharmaceuticals that are not fully removed from waste water and can exert biological effects, even after transformation. Their input in the

environment is continuous - they are used in many fields such as aquaculture, agriculture, veterinary and human medicine - and made to be biologically active at low concentrations. An indirect consequence for public health of antibiotic presence in the environment is the selection for resistant bacteria. Target analyzed chemicals often explain only a fraction of the effect observed in a specific bioassay. Hence there is a need to identify other potent chemicals responsible for such measured effects. We aim to develop a bioassay that detects the presence of antibiotic-like compounds in (water) extracts and can be used as high-throughput assay in effect-directed analysis. Bioassay-guided identification of antibiotic-like compounds may result in the identification of unknown compounds with antibiotic properties, or metabolites and transformation products of antibiotics. Four Gram-negative and three Gram-positive strains were selected based on increased susceptibility to antibiotics or their particular read-out, such as constitutive expression of luminesence or green-fluorescent protein (GFP). Further, the use of resazurine as indicator of metabolic activity was determined. The bacteria were exposed to serial dilutions of antibiotics and the MIC90 was determined as the minimum test concentration causing ≥90% inhibition of growth compared to a control. Two bacterial strains were selected for further development of a bioassay, that can be used for the identification of antibiotic-like compounds with effect-directed analysis. The available read-outs for these strains are bacterial density and resazurine reduction. In the presentation, we will demonstrate the sensitivity of these strains to antibiotics with high use in the Netherlands (>50,000 users a year). In addition, assay results will be presented with spiked and field samples.

Ecotoxicology of Nanoplastics: Mechanistic Approaches to Understand Their Risk for the Environment and Human Health

235

The effect of chemical and biological conditioning on the chemical toxicity of microplastics to Daphnia magna under various exposure conditions.

K. Reilly, The University of Birmingham; F. Nasser, University of Birmingham; L.A. Ellis, The University of Birmingham / GEES; J. Sadler, The University of Birmingham / Geography Earth Environmental Science; I. Lynch, University of Birmingham / Geography Earth Environmental Science

Microplastics are a widespread pollutant of concern that are found in aquatic environments across the globe, including in arctic sea ice, coral reefs and deep ocean trenches. There has been increasing scientific research on this topic in recent years which has led to societal and media engagement and ultimately policy and industry changes. The research to date has demonstrated the toxic potential of microplastics in the environment, which usually manifests as a dose-dependent response. This research explores the potential effects of polyethylene spheres (PE) when combined with selected substances of environmental concern (DEET, Triclosan and Diclofenac) on the model organism *Daphnia magna* (water flea). This research compares toxicity under different exposure conditions to ascertain the potential combined (mixture) toxicity effects under realistic (competitive) exposure conditions with both chemical and biological molecules. Corona formation due to biomolecule adsorption onto plastic particles changes their surface characteristics which can affect subsequent biological and chemical interactions. We compare the effect of different chemical and biological conditioning scenarios on PE particles and the combined effects on *Daphnia magna*. Chemicals were selected from different groups to explore a range of potential effects included insecticide (DEET), antibacterial (Triclosan) and pharmaceutical (Diclofenac). The study was broken into 3 main questions aiming to assess any variation in effects due to the sequence and combination of exposures; 1) What effect does competitive binding have on the adsorption of chemical (co-pollutant) and proteins onto the plastic surface when exposing the plastics to mixture of chemical and *Daphnia-conditioned* medium. 2) How much co-pollutant will be adsorbed into the eco-corona of a preconditioned microplastic, therefore increasing the chemical load? 3) Does the protein corona offer a pathway to reduce toxicity by displacing any of the chemicals on a previously chemically conditioned microplastic, therefore decreasing the co-pollutant load? Toxicity effects were classified using a range of standard OECD tests and end points. The effect that the artificial chemical and natural biological conditioning of the microplastics has on chemical adsorption and desorption rates were key elements of this study, to ascertain how contaminated microplastics may form part of a more complex pollution issue in the natural environment.

236

Biointeractions and toxicity of microparticles from waste plastics in in vitro and in vivo systems

P. Mantecca, University of Milano - Bicocca / Department of Earth and Environmental Sciences; M. Saibene, P. Bonfanti, A. Colombo, University of Milano Bicocca

Microplastics (MPs) represent a worldwide concern toward human and environmental health due to their intentional or unintentional release. Environmental MPs are irregular in size, shape and composition. These characteristics make the study of the biological impact of heterogenous MPs of extremely high relevance to better estimate the real toxicological hazards deriving from human and environmental organisms exposure. In the present we used micrometer-sized plastic particles obtained by the fragmentation of plastic wastes of a miscellaneous origin. From the collection and treatment of these plastic fractions is possible to achieve a second-generation plastic material in a granulated form, mailnly constituted by micrometer-size granules. The smallest fractions of the plastic granules, considered as representative of the environmental MPs, have been used to perform toxicity tests using *in vitro* and *in vivo* systems representative of an inhalation and aquatic exposure scenarios respectively. The plastic granulates were mechanically grinded in lab to obtain MP fractions of < 100 μm and < 50 μm. MPs where morphologically charaterized by light and electron miscroscopy techniques and by ATR-FTIR spectroscopy. To evaluate the inhalation toxicity, cell viability and pro-inflammatory responses were evaluated in human alveolar A549 cells. To evaluate the toxicity toward aquatic organisms, amphibian *Xenopus laevis* embryos exposed to MPs were scored for mortality, malformations and growth retardation. Embryos were also histologically analysed to evaluated MP-tissues interactions. MPs resulted very irregular in size and shape, and mainly constituted by PE and PP. The effects on A549 cells resulted size-dependent, with the smaller MPs inducing decrease in cell viability and increase in pro-inflammatory cytokine release. MPs did not induce significant lethal and malformation effects in developing *Xenopus* embryos, while some embryos showed abnormal gut coiling. MPs accumulated into the gut, where lesions at the intestinal mucosa level were evident, together with MPs in contact and/or internalized into epithelial cells. The present results highlighted the importance to study the effects and the biological mode of action of environmental MPs, which greatly vary in size, shape and polymer composition. The mechanic stress toward epithelial cells may represent a triggering event for the pro-inflammatory response.

237

Nanoplastic trophic transfer and dietary effect using plant and snail in terrestrial ecosystem

Y. Chae, Konkuk University; Y. An, Konkuk University / Department of Environmental Heath Science

Plastic pollution in soil environment has increased and the concerns about their effects on soil ecosystem are getting attentions in these days. Especially, among plastic wastes, small sized plastic particles like microplastics (MP, < 5 mm) and nanoplastics (NP, < 1 μm) are getting a lot of attentions. Researchers are focusing on the fate, distribution, and ecological impacts of these plastics. In this study, we investigated the adverse effects of NPs on the organisms in soil ecosystem and the transfer of NPs in the food chain containing crop plant *Vigna radiata* and snail *Achatina fulica*. During 14 days, *A. fulica* consumed *V. radiata* which had grown in the NP contaminated soil for 10 days. After exposure, we investigated the adverse effects of NPs on *V. radiata* (shoot and root growth) and the distribution of NPs in plants transferred from soil to plant. We also investigated the impacts of NPs on *A. fulica* (growth rate, food consuming time, and histopathology) and NP ingestion and egestion via food exposure. In results, NPs entered the plants and transferred to snail through food chain. NPs also induced the growth of plant (decrease of diameter of root). In the case of snail, the growth (weight) of *A. fulica* exposed to high concentration of NP significantly decreased and food consuming time of exposed snail significantly increased (high concentration only) from 4th day of exposure. This can be the evidence of disturbance effects of NPs on the motion of snail. Additionally, damaged tissues were observed in the organs from NP exposed snail and NPs were detected in the feces of *A. fulica*under fluorescent microscope. This indicates that indirect or secondary pollution can occur through ingestion and egestion activities of organisms in soil ecosystem. We confirmed that both direct and food exposure of NPs can induce adverse effects of soil organisms and NPs can be transferred via food exposure in soil ecosystem. *Acknowledgement - This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT, and future planning (2016R1A2B3010445).*

Environmental risks of nanoplastics? Defining a size threshold for assessing intake of plastic particles in tissues, organs and cells.

T.C. Schell, IMDEA Water Institute / Ecotoxicology; A. Rico, IMDEA Water Institute / Aquatic Ecotoxicology; M. Vighi, IMDEA Water Institute / Earth and Environmental Sciences

Plastic pollution is a problem of critical environmental concern and comprises the majority of anthropogenic debris in the environment, including macro, micro, and nanoplastics. So far, the definition of macro, micro and nano-plastics is based on a pragmatic choice. According to one of the most commonly used definitions, microplastics are in the range of 5 mm to 1 mm, while fragments below 1 mm are classified as nanoplastics. However, this classification does not entail any ecological or functional justification. Microplastics may be ingested by animals and may have physical effects of various types. Moreover, they may absorb bioaccumulative toxic chemicals that could be released into the intestinal tract, the so called "Trojan horse" effect. However, microplastics are chemically inert particulate material and cannot cross cell membranes and bioaccumulate. So far, there is some evidence that nanoplastics can enter living cells and bioaccumulate. The objective of this study is to experimentally determine at which size threshold plastic particles may be able to cross the walls of the digestive tract of living organisms, and thus enter cells and bioaccumulate. A test is performed with one-week old adult *Daphnia magna individuals*, in glass beakers with 100 ml ASTM medium and polystyrene nanoparticles of 20, 50, 100, 200, 500, 1000 nm diameter, labeled with Fluorescein. The test is performed in duplicate. The approximated concentration of particles in the test medium ranges from about 10^6/ml (1000 nm diameter particles) to about 10^{11}/ml (20 nm diameter particles). The animals are exposed for 48 hours (three specimens) and 96 hours (three specimens) in order to allow the ingestion of plastic particles in sufficient amounts and to be translocated to other tissues and organs inside the animal. *D. magna* are fed with *Pseudokirchneriella subcapitata*. The specimens collected after 48 hours and at the end of the experiment are sacrificed and fixated with formalin. The presence of plastic particles in the digestive tract and in tissues is examined with Confocal Laser Scanning Microscope (CLSM) to evaluate the bioaccumulation capability of different plastic particles. The results of this study may contribute to the development of a more relevant definition to assess the risks of nanoplastics for ecosystem's and human health

What's on the outside matters - surface charge and transformations affect toxicity of polystyrene nanoparticles to C. elegans
C.L. Schultz, Centre for Ecology and Hydrology; J. Baas, D. Spurgeon, Centre for Ecology & Hydrology
With increasing concern about the occurence of plastic particles in the environment, the need to identify the physicochemical properties influencing their toxicity has been recognised. Whether materials at the nanoscale are released as particulates or occur through the weathering of larger plastics once in the environment, they are subject to (further) transformations in waste streams and natural systems. Initially, such processes likely occur at the particle surface through the attachment of molecules present in these systems, thus altering the interactions at the bio-nano interface. Investigating particles with varying surface coatings may shed light on the influence of such interactions on observed toxic effects. In this study, we tested the toxicity of 50nm polystyrene nanoparticles with different surface charges on life history traits of the nematode *Caenorhabditis elegans*. Exposures were carried out from egg and nematode lifespan, growth and reproduction measured over time. Differences in the toxic effects of the pristine materials were established. Positively charged (amine coated) particles were found to exert the greatest toxicity, followed by the neutral (unfunctionalised) particles, whereas negatively charged (carboxyl coated) particles did not influence nematode fitness at the tested concentrations. Further, the aim of this study was to understand how the absolute and relative toxicity of nanomaterials with different starting characteristics change once they have been aged in soil pore waters, in particular how environmental transformations may lead to a convergence of observed toxicities as compared to those of pristine forms under standard laboratory test conditions. To address this, in addition to the assays with "pristine" particles, exposures will be conducted with nanoparticles incubated in pore waters extracted from a field soil for a week prior to testing. Dynamic energy budget toxicity (DEBtox) modelling will be applied to analyse toxic responses with regard to resource allocation. The DEBtox approach uses time resolved data to derive toxicity parameters, e.g. the no effect concentration, which can be used to compare the effects of particle surface properties within each test condition as well as across the pristine and aged exposures. Together, this data will be used to provide insights into the influence of surface coatings and changes thereof in natural systems on nanoplastic toxicity and associated processes.

1. Introduction MONITOOL[1] is a European project formed by 17 Partners covering the Atlantic region from the Canary Islands to the Scottish Highlands and Islands, and one Partner from the Mediterranean region. The main driver of this project is to respond to European Water Framework Directive (WFD)(2000/60/EC) demands for the assessment of the chemical status (CS) of transitional and coastal waters. The WFD establishes that the CS of water bodies must be determined by the comparison of the concentrations of priority substances with Environmental Quality Standards (EQSs), mainly based on the collection of spot water samples. Diffusive Gradient in Thin Films (DGT), and passive samplers (PS), in general, are already widely used in investigative monitoring and there is an interest in their use in the context of the WFD. The main barrier hindering the regulatory acceptance of PS is the lack of appropriate EQS: EQSs in water are defined in the dissolved fraction, preventing the use of DGT-labile concentrations. Thus, the overall objective is to adapt the already existing EQSs for water to those for DGTs, enabling their use for regulatory monitoring. 2. Materials and methods In 2018, two campaigns were carried out in winter (rainy season) and in summer (dry season); simultaneous deployment of DGTs and high-frequency collection of spot water samples were carried out. The sampling campaigns were performed in 4 selected sites (transitional and coastal sites) in each of the 8 European regions (32 sites in total). At the estuarine sites, water samples were taken every day in high and low tide during the DGT deployment period (5 days). All partners used the same DGT supplier and followed the same sampling and analysis protocol. Physico-chemical parameters in water were measured every sampling day. Priority metals (Cd, Ni, Pb) and other specific metals (Al, Ag, Cu, Cr, Co, Fe, Mn, Zn) were analysed in waters and in the DGT resins. **3. Preliminary results** From winter campaign, 230 seawater samples and 140 DGT samples from the 8 consortium regions were analysed. Physico-chemical data and metal concentration results are being collected in a common data base. Preliminary statistical analysis were applied to first results to study relationships between metal concentrations in DGT and in spot water samples. In a final step, suitable EQS for DGTs will be calculated based on the statistical relations obtained previously. [1]https://www.monitoolproject.eu/

Evaluation of Effects Based Methods for Regulating Metals in Aquatic Ecosystems
K. Brix, EcoTox / Marine Biology and Ecology; S. Baken, European Copper Institute; J. Mertens, EPMF; C. Cooper, International Zinc Association / Department of Marine Sciences
The European Union is currently evaluating the use of Effects Based Methods (EBMs) as part of a more integrative strategy for regulating a number of substances of concern under the Water Framework Directive. This paper evaluates the use of thirteen EBMs that have potential for being applicable for the regulation of metals. Each EBM was evaluated with respect to three criteria: a) metal specificity and sensitivity; b) sensitivity to other classes of toxicants; and c) the strength of the relationship between effects measured by the EBM and effects observed at higher levels of biological organization, such as the individual or population level. The evaluation concluded that none of the EBMs evaluated met all three criteria. The current EU approach of regulating metals is based on Environmental Quality Standard (EQS) assessments (where necessary and where possible, corrected for bioavailability). This approach is sensitive only to metals and has strong links to effects at the individual and population level. It does not, however, consider the integrated effects of metal mixtures on aquatic systems. Given the lack of suitable EBMs for metals, one recommendation would be the continued development of bioavailability models for predicting the toxicity of metal mixtures. Such bioavailability-based metal-mixture models may be the most effective way to achieve the goal of a more holistic approach for regulating metals in aquatic ecosystems.

243
Correcting for metal bioavailability in European freshwaters: where do the data come from to make this happen?
I.A. Wilson, A. Peters, G. Merrington, wca; A.C. Ryan, Windward Environmental LLC; B.A. Stubblefield, Oregon State University / Environmental and Molecular Toxicology
In this presentation we will outline the process and outputs from a project in which we have collated and assessed data collected by member states for freshwaters across Europe from which bioavailability correction can now be

made. These data can be used for future bioavailability assessments and to provide context for individual member states, especially where river basins cross national boundaries. This project also provides an opportunity to identify gaps in data coverage and allows member states to target and prioritise resources to enable robust trace element bioavailability compliance assessment. A step-wise process was followed to systematically obtain, screen, and quality assess the available data. Data obtained were from EU member states, via various sources including centrally hosted data archives, data compiled by the European Environment Agency (EEA), contacts at environment agencies through-out Europe, and direct contact to environment agencies. Initial data searches focused on obtaining as much information as possible; the targeted information was separated into categories. Essential data were pH, DOC and Ca; desirable data were Mg, Na, K, Cl, SO_4^{2-}, total and dissolved Cu, total and dissolved Ni, total and dissolved Zn and total and dissolved Pb, and added value data were conductivity, hardness, Fe, Al and other trace elements. After compilation, an initial screening was performed in terms of having the primary relevant sample/site, information and the specific 'essential data'. Following the screen, a quality assessment was implemented; this assessment was based on the ECHA guidance on the use of measured data and particularly on requirements for the use of measured data. Initial results show that although large amounts of data are generated on water quality throughout Europe; the public availability of these data, the determinands assessed, and the quality of the data is hugely variable. Where high quality data are available, it can be used for performing bioavailability assessments, which indicate areas that may be specifically sensitive to metals, both within Europe and within member states. Furthermore, by collating all available information, and by retaining datasets with data-gaps, areas where key parameters are either not measured, or are of poor quality, and significantly hampering the bioavailability assessments of waters are identified.

244
Validation of Bio-met for the site specific bioavailability normalisation of EQS for copper, nickel, and zinc
A. Peters, G. Merrington, I.A. Wilson, wca; F. Verdonck, ARCHE; C. Nys, Arche consulting / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; C. Cooper, International Zinc Association / Department of Marine Sciences; F. Van Assche, IZA; S. Baken, European Copper Institute; C.E. Schlekat, NiPERA
Bio-met is a user-friendly tool which has been developed to simplify the process of adjusting European Environmental Quality Standards for metals in freshwaters for local bioavailability conditions. An important aspect of why Bio-met is that it removes the need for users to have expertise in metal speciation, ecotoxicology, and bioavailability in order to obtain bioavailability normalised results. This is achieved by using look-up tables of previously performed calculations with the tool selecting the most appropriate result from the look-up tables according to the water chemistry conditions. The results which Bio-met provides convert the EQS-bioavailable which is expressed as "bioavailable metal" into a site specific local HC_5 value which is expressed as a "dissolved metal" concentration and can be compared against monitoring data. At the same time, Bio-met calculates the corresponding bioavailable fraction of the measured (dissolved) concentration of the metal. There are a number of ecotoxicity studies which have been performed in field collected natural water samples in order to provide validation evidence for the Biotic Ligand Models (BLMs) which have been developed to predict metal bioavailability for individual species in natural waters. These studies are available for the same species as where used for BLM development, and in some cases also for other species to which the BLMs are applied. This work makes clear the connection between the validation tests using field collected natural waters and the local HC_5 which is calculated by the user-friendly tool Bio-met, by calculating the local HC_5 for the waters used in the BLM validation studies. When the calculation is performed using the full BLMs the EC10 value for each individual species is calculated in order to generate the site specific SSD from which the local HC_5 is derived. Bio-met provides users with the end result only, i.e. the local HC_5 (or bioavailable metal concentration), without providing the intermediate calculations which are used to compile the SSD.

245
A framework for metals read-across: a case study with cobalt carboxylate compounds
B.A. Stubblefield, Oregon State University / Environmental and Molecular Toxicology; P. Marsh, CI; P. Campbell, Université du Québec / INRS Eau Terre Environnement
Regulations such as the European Union's REACH (**R**egistration, **E**valuation, **A**uthorisation and Restriction of **Ch**emical Substances) Regulation and the US's Toxic Substances Control Act (TSCA) require a greater understanding of the use and disposal of chemicals in the environment. All require greater information and the development of more empirical data regarding the fate and toxic properties of chemicals in commerce and in the environment. Satisfying these goals requires either the development of vast amounts of chemical specific data or the evaluation and estimation of the chemical and toxicological properties of these substances. Couple with this need for data, the increasing pressure to comply with societal desires to reduce the amount of animal testing conducted, and it is clear that alternate approaches must be developed. One potential approach is to estimate the properties of one "target" chemical, based upon information developed for a similar "source" chemical, a "read-across" approach. Metals, in particular metal salts with inorganic and organic acids, present a unique case for application of a read-across approach. For the most part, current regulatory approaches for control of aquatic metals concentrations are based on measured metals concentrations and then, with some exceptions, are based on the operationally defined "dissolved" fraction. Toxicity testing is typically conducted using readily soluble metal salts and test results are evaluated using measured dissolved metal concentrations; resulting regulatory standards are for the measured metal. In general, this approach assumes that the test material will dissociate in water into its cationic and anionic components and that the toxicological effects observed can be attributed to the components or any bioavailable (i.e., dissolved) species formed. Results from these tests are used to interpolate to other metal salts based on the measurement of dissolved measured metal concentrations. The validity of this approach has been evaluated for select cobalt compounds. Chronic toxicity studies were conducted with a range of cobalt-containing salts and results compared with tests performed on a cobalt inorganic salt, cobalt dichloride. A framework for the evaluation of metals salts, in general, will be proposed.

246
Derivation of a protective threshold value for silver towards freshwater organisms
K. Arijs, ARCHE
Driven by EU REACH and the EU Water Framework Directive (WFD), the dataset of available chronic freshwater data for silver was re-evaluated using strict quality criteria. In addition, a testing program was established to generate new chronic ecotoxicity data with potentially sensitive species in order to strengthen the species sensitivity distribution (SSD) for silver. Tests were performed with the plant *Lemna minor* (7-day growth rate test, OECD TG 221), the cyanobacteria *Anabaena flos-aquae* (72-hour growth rate test, OECD TG 201) and the rotifer *Brachionus calyciflorus* (48-hour population growth rate test, APHA test procedure 8420). The critical review of chronic freshwater toxicity data for silver and the additional testing has strengthened the SSD for silver (covering 17 species in 12 taxonomic groups). The dataset includes data for cyanobacteria, which were considered to be particularly sensitive to silver (cfr. anti-microbial properties of silver ions). The corresponding reasonable worst-case PNEC is 0.042 μg Ag/L (< 0.45 μm fraction), and is 2.4 times lower than the lowest EC_{10} in the SSD (*P. subcapitata*). The PNEC is considered adequately protective for sensitive freshwater organisms. Furthermore, the silver PNEC is conservative in terms of bioavailability: the selected chronic toxicity data typically reflect conditions of high bioavailability, with hardness and DOC well below median values in EU natural waters. Industry is currently considering the development of a bioavailability model for silver. The resulting revised freshwater chronic PNEC will be included in the REACH registration dossiers for silver and silver compounds, and is being fed into the discussions ongoing at European Commission level, where silver is being considered as a potential priority substance under the EU WFD.

Modelling and Monitoring of Pesticides Fate and Exposure in a Regulatory Context (II)

How the multi-year FOCUS surface water modelling will change the risk assessment
B. Kind, J. Kleinmann, K. Billau, WSC Scientific GmbH
For the registration of plant protection products in the EU, a safe use with regard to surface water and sediment organisms needs to be demonstrated. The FOCUS work group developed a stepwise approach. At step 3 different models for drainage, runoff and spray drift entry into different surface water bodies were combined. Due to limitations of these models, the modelling period was limited to 12 - 16 months. Currently the possibility to run multi-year simulations at step 3 is discussed and an approach was presented by EFSA (2018). In the present study multi-year runs were performed using AutoPEC SW to evaluate the possible consequences of an extension of the modelling period for the final risk assessment in surface water and sediment. In the draft scientific report EFSA proposed to implement a number of changes to the exposure calculation in surface water and sediment independent of the extension of the run-time. Some of these adaptations like omitting the Pesticide Application Timer (PAT) or using 90^{th} percentile drift deposition for each individual application were applied to exposure calculations. The resulting PEC values used for the aquatic risk assessment are compared and discussed in this presentation. Additionally, various temporal percentiles for the exposure assessment were evaluated using exposure profile analysis conducted with the software PEC Robot to compare the resulting PEC values with the actual exposure over the whole modelling period. It turned out that weather conditions do have an impact on the amount of substances reaching surface water and sediment via drainage and runoff. Hence, the selection of the application dates based on a PAT seems to be reasonable and should be used also for the multi-year

assessment. For calculations with unrealistic application dates (without PAT) it was found that the use of the 80th percentile PEC_{SW} from all simulation years results in a more balanced PEC_{SW} than the maximum PEC_{SW} of all simulation years, since the maximum PEC may overestimate the exposure to aquatic organisms. However, an exposure profile analysis has shown that the 80th percentile PEC_{SW} from multi-year simulations is only protective if there is just a short, single exposure peak while it may not be protective enough when a single peak lasts for a longer period. The selection of an appropriate endpoint from PEC simulations will be discussed.

248
Retention of veterinary antibiotics and herbicides in biochar amended tropical soils
G.O. Aldana, Newcastle University / School of Natural and Environmental Sciences; C. Hazlerigg, Enviresearch Ltd; E. Lopez-Capel, Newcastle University / School of Natural and Environmental Sciences; D. Werner, Newcastle University / School of Engineering
Agrochemicals have long been used as an effective method to optimize food production in tropical regions. However, the improper use of agrochemicals have been found to cause detrimental effects to natural ecosystems and human health due to their tendency to contaminate surface, ground and drinking water. Biochar has been reported to reduce the leaching of agrochemicals in soils. Studies observe that the potential to reduce leaching is determined by the biochar, agrochemical, and soil properties. The aim of this study is to identify biochar materials that will retain agrochemicals from leaching in tropical soils, therefore reducing their environmental impact. Since the sorption capacity of biochar materials vary depending on temperature and feedstock, this study tested the sorption properties of rice husk, miscanthus straw and softwood pellet biochars produced at 700? to remediate three veterinary antibiotics (enrofloxacine, tetracycline, oxytetracycline) and two herbicides (atrazine and diuron) from contaminating three contrasting tropical soils. Batch studies were carried out and leachates were analysed using High Performance Liquid Chromatography (HPLC). Results showed that amongst all three biochars, rice husk biochar displayed the highest absorption for all agrochemicals tested. Tetracycline held the highest absorption distribution coefficient (K_d) of 5.29 m^3/kg amongst the veterinary antibiotics, while diuron held the highest K_d of 1.13 m^3/kg amongst the herbicides studied. In addition, soils amended with rice husk biochar (2.5% w/w) showed an absorption increase for all agrochemicals. This increase was more pronounced for atrazine in biochar amended loam and sandy silt loam soils. The impact of biochar use on the regulatory risk assessment of agrochemicals was explored further by manipulating soil characteristics in the PEARL model using standard groundwater scenarios (Sevilla and Thiva) with properties of these biochars such as organic carbon, bulk density and hydraulic properties. Incorporation of these biochars in the PEARL model resulted in reduced Predicted Environmental Concentrations in groundwater (PEC_{GW}). In conclusion, applying biochar could provide a cost-effective risk mitigation strategy for agricultural stakeholders. Further studies must be dedicated to exploring the sorption effects of biochar in a tropical climate at the field scale.

249
Sorption and degradation of diflufenican in the urban environment
S.B. Svendsen, Aarhus University / Enviromental science; P. Carvalho, Aarhus University, Department of Environmental Science / Department of Environmental Science; U. Bollmann, Geological Survey of Denmark and Greenland / Environmental Science; L.E. Jensen, Aarhus University / Environmental Science; C.N. Albers, Geological Survey of Denmark and Greenland / Department of Geochemistry; B.W. Strobel, University of Copenhagen / Plant and Environmental Sciences; C.S. Jacobsen, Aarhus University / Department of Environmental Science; K. Bester, Aarhus University / Environmental Science
Diflufenican is a herbicide approved for use in agricultural and urban areas. The approval is based on data obtained for cultivated soils only, while limited knowledge is available on its fate in urban areas. Urban soils typically contain low amounts of organic matter and microorganisms – a situation known to decrease sorption and degradation of many herbicides. In the present study, sorption, mineralization and degradation of diflufenican were investigated on laboratory scale, using a typical urban gravel and a cultivated soil sampled in Denmark. Sorption and degradation were studied for diflufenican and its two aerobic metabolites AE-B and AE-0, while mineralization studies were solely for diflufenican. Diflufenican sorbed strongly to the soil ($K_F = 96$) and much less to the gravel ($K_F = 9$), while the two metabolites showed much less sorption than diflufenican ($K_F = 3.8$ and $K_F = 0.63$ in soil for AE-0 and AE-B, respectively, and $K_F = 1.1$ and $K_F = 0.53$ in gravel for AE-0 and AE-B, respectively). Cumulated over the entire experiment, no mineralization was detected in the gravel, while only approximately 10% of the initial diflufenican concentration had been mineralized in the soil. Diflufenican, AE-B and AE-0 all showed a slower degradation in soil than in gravel. AE-B was formed from diflufenican degradation in both soil and gravel. In the soil there were no indications of accumulation of AE-B, however, in gravel, AE-B kept accumulating over a period of 150 days. The data obtained in the present study shows a situation with limited sorption of diflufenican and its two aerobic metabolites in gravel. Furthermore, no mineralization and only a slow degradation could be detected in gravel, giving rise to the concern for an elevated risk of leaching and groundwater contamination in urban areas. This is of especial concern for the highly mobile metabolite AE-B, which formation pattern in gravel showed no indications of reaching a plateau during the 147-days study period.

250
How to Design, Implement and Interpret Groundwater Monitoring Studies in an EU Regulatory Context
D. Wallace, Syngenta; P. Sweeney, Syngenta / Environment Product Safety
Regulations in Europe offer a tiered system by which potential impact of the use of an active ingredient on groundwater can be assessed through a variety of differing options; modelling, semi-field and field. With the Tier 1 model and parametrisation thereof becoming increasingly conservative, an increasing number of higher tier evaluations of GW are being conducted and submitted to Regulatory Authorities. As part of the SETAC group, a thorough revision of how different types of monitoring studies could be conducted and the different protection goals was reviewed. However, the SETAC-EMAG group therefore provided an overview of different monitoring study designs but did not provide any practical framework for interpretation or use in the Regulatory risk assessment. An EU monitoring study was conducted to define a 90th percentile EU groundwater concentration as outlined in SANCO/13144/2010 version 3 and demonstrate safe use. Data evaluation reveals that 90th percentile concentrations of S-metolachlor, ESA (CGA354743) and OXA (CGA51202) to be below trigger, however has been rejected as a design principle, and as such the study re-evaluated to FOCUS scenarios. Instead, the current Regulatory evaluation considers only absolute max. Building on the momentum of SETAC-EMAG, we propose a pragmatic but yet conservative interpretation framework which will allow integration to the current regulatory system.

Comparison of AGDISP-predicted off field deposition for ground applications using various nozzles and operational conditions
H. Rathjens, STONE EnvironmentalEngineering & Science,Inc. / Environmental Modeling Systems; J.M. Brausch, BASF Corporation; M.F. Winchell, STONE EnvironmentalEngineering & Science,Inc. / Environmental Systems Modeling; A. Goetz, BASF Corporation
Nearly all pesticide spray applications result in some off-target drift due to wind movement, spray solution characteristics, weather, and applicator decisions. In 2013, BASF conducted a field study to measure off-field drift from ground applications of several compound-nozzle combinations. Based on the evaluation of the data collected from this field study, the US EPA determined appropriate spray buffers required to meet protection goals for effects to non-target plants. In order to evaluate the drift potential of a wider range of nozzles and drift reducing adjuvants (DRA), an analysis that combined wind tunnel experiments with drift modelling was initiated to determine which combinations of nozzles and DRAs would result in off-site deposition less than or equal to “benchmark” setups analysed in the field study. As a first step, BASF conducted wind tunnel studies to gather information on the produced droplet spectrum data for various nozzles and tank additives. The second step of this assessment was to use the droplet spectra from the wind tunnel experiments as inputs to the model AGDISP to predict potential off-target drift deposition. The predicted spray drift depositions were used to assess the nozzles and tank mix combinations for drift vulnerability by comparing the model results to model predictions for the field study benchmark. Using relative comparisons of AGDISP-modelled drift deposition results removed any bias that might have arisen from the wind tunnel conditions at the time of the experiment or that are inherit to the model used (AGDISP). The AGDISP model results of over 3,000 treatments indicate that operational conditions such as windspeed, use of DRAs, boom height, and nozzle type have a significant impact on off-target drift deposition that should be considered as measures for mitigating spray drift. The study demonstrated that results from field, wind tunnel, and modeling experiments can be combined to determine which combinations of nozzles, DRAs, and operational conditions could be used to meet protection goals. It was further demonstrated that relative comparisons of ground application AGDISP model results are an efficient method to assess the impact of various parameters that can be used for mitigating off-target spray drift deposition.

Fish Model Species in Human and Environmental Toxicology (II)

253
The visual impairments of zebrafish larvae induced by 2,2′,4,4′-tetrabromodiphenyl ether (BDE-47)
T. Xu, Tongji University / College of Environmental Science and Engineering; B.

Zhang, Tongji University / College of Enivironmental Science and Engineering; S. Wei, D. Yin, Tongji University / College of Environmental Science and Engineering

The underlying mechanisms of adverse effects of flame retardant BDE-47 on neurobehavioral toxicity were highly concerned, and our previous study indicated that the changes of zebrafish locomotion were plausibly associated with their affected visual sense. To investigate the relationship between BDE-47 exposure and zebrafish visual impairments, a series of experiments covering molecular, morphological and behavioural levels were designed and performed. First, we utilized RNA sequencing to seek vision-related responsive genes of BDE-47 exposure, and validated the sequencing outcomes using qRT-PCR. Both results declared BDE-47 could disrupt the expressions of light-sensitive opsin genes which specifically exist in rods and cones of retina, and four mid-short wavelength sensitive opsins (opn1sw1, opn1sw2, opn1mw1, and rho) were most significantly inhibited. The expression changes of opsins indicated an impaired spectral sensitivity to blue-green light and dim light. Tissue sections and immunostaining were adopted to provide morphological evidences for molecular clues. Histologically, disorderly arranged photoreceptor layer (composed of rods and cones) in retina were observed after BDE-47 exposure. photoreceptor layer, bipolar cell layer and ganglion cell layer were thicker with a more sparse cell distribution in BDE-47 treatments than in the control. Furthermore, decreased rhodopsin fluorescence and unaltered fluorescence from red-green double cones were observed, which were consistent with the changes of opsin genes. In the section of behavioural testing, improved OKR and stumili-evoked escape (looming) responses were employed. BDE-47 exposure significantly reduced the larval OKR response to the blue light but not the mid-long waveband lights. Additionally, larval left eyes had fewer movements than the right eyes after BDE-47 exposure. Escape response is an excellent candidate test emphasizing the roles of visual factors in behavior of animals living in real ecosystems. In the results, the amounts of responsive fish significantly reduced with BDE-47 exposure, reflecting BDE-47 impaired larval behavioral capacity with sensing ambient visual stimuli. Our results indicated that BDE-47 exposure impaired zebrafish larval vision (including color vision) development, and further altered larval behaviours guided by vision, which provided adequate evidence to prove that vision system was a novel and urgent toxicological target of environmental pollutants.

254

Can environmentally relevant neuroactive chemicals specifically be detected with the locomotor response test in zebrafish embryos?

D. Leuthold, Helmholtz Centre for Environmental Research - UFZ GmbH / Bioanalytical Ecotoxicology; N. Klüver, Helmholtz centre for environmental research - UFZ / Department of Cell Toxicology; R. Altenburger, UFC Centre for Environmental Research / Department Bioanalytical Ecotoxicology; W. Busch, Helmholtz Centre for Environmental Research - UFZ GmbH / Bioanalytical Ecotoxicology

Chemicals considered as neuroactive (e.g. certain pesticides, pharmaceuticals, industrial chemicals) represent one of the most diverse groups of bioactive substances recently detected in European river catchments. Even though the environmental presence of these substances raises concerns, the determination of nervous system-specific effects has been limited using *in vitro* tests or conventional endpoints including mortality. Thus, complementary approaches such as neurobehavioral tests with alternative *in vivo* models like the zebrafish embryo (ZFE) have been proposed. Here we present our new study where we found that exposure of 4-5 days post fertilization (dpf) ZFEs to a set of 18 environmentally relevant compounds with various modes of action (MOAs) led to concentration and time dependet behavioral effects. These behavioral alterations were not restricted to chemicals primarily known to target the nervous system but rather comprised of compounds with anticipated non-neuroactive MOAs too. Furthermore, chemicals with an anticipated same MOA did not necessarily provoke similar behavioral phenotypes. Therefore, a clear distinction of mechanisms on the basis of locomotor patterns for the analyzed set of compounds was not possible so far. Our results suggest that the acute MOAs of certain environmental contaminants in ZFEs are not yet elucidated and that some of them may have unknown neuroactive potentials whereas other compounds considered as neuroactive in e.g. invertebrates may not act or act differently on the nervous system in the ZFE. Furthermore, there is a need improve the specificity of the light-dark transition test when aiming at using it as a diagnostic tool. In addition to specificity of locomotor responses, we found that their sensitivity compared to mortality within the same 24-hour time window (4-5 dpf) and even developmental 4- or 5-day exposure (0-4 or 5 dpf) was increased (≥10-fold) for the majority (5/8) of investigated neuroactive compounds but for none of the other substances. Our results substantiate that locomotor behavior can represent a sensitive endpoint for certain neurochemicals.

255

Turquoise killifish (Nothobranchius furzeri) as a new model in behavioural ecotoxicology

E. Thoré, L. Steenaerts, C. Philippe, KU Leuven; L. Brendonck, KU Leuven / Laboratory of Aquatic Ecology Evolution and Conservation; T. Pinceel, KU Leuven

Pharmaceuticals are essential for human wellbeing. However, due to their increasing and continuous use, sub-lethal concentrations of pharmaceutical compounds have already been detected in the aquatic environment. As these compounds are designed to elicit specific biological effects at low concentrations, standard ecotoxicity tests are unable to correctly assess environmental risks associated with pharmaceutical pollution. Reproducible tests that are based on sensitive behavioural endpoints and that accommodate a high ecological relevance have been promoted to fill this gap. We assessed the impact of a three-week exposure to the antidepressant fluoxetine on behavioural traits in *Nothobranchius furzeri* (Turquoise killifish). Overall, this study shows that fluoxetine can impact life skills, such as feeding behaviour, habitat choice in a novel environment and antipredator response of *N. furzeri* individuals while effects on basic behavioural traits were less clear. *N. furzeri* has recently been introduced as a novel model organism for standard ecotoxicological tests and now its potential for behavioural ecotoxicology is being explored.

256

Copper nanoparticles impair the mechano-sensory based behavior of zebrafish embryos (D. rerio)

M. Burkard, Eawag Aquatic Water Science / Southern Ocean Persistent Organoic Pollution Program; Y. Yu, Nanjing Tech University; C.M. vom Berg, K. Schirmer, Eawag Swiss Federal Institute of Aquatic Science and Technology / Environmental Toxicology

Metal oxide nanoparticles such as copper-based engineered nanomaterials (ENMs) are used in a wide range of commercial products and applications. Herein, we investigated the impact of newly synthesized CuO-ENMs by assessing different mechano-sensory based behavioral responses of zebrafish (*Danio rerio*) embryos (ZFE). As a first step, we composed a CuO-ENM dispersion- and exposure medium to mimic the natural environment of zebrafish by including natural salts and natural organic matter. Larvae were exposed for 4 hours starting at 96 hours post fertilization (hpf) to non-toxic concentrations of CuO-ENMs. Upon exposure, neither locomotion (swimming distance) nor the startle response (escape reaction upon vibration stimulus) were affected. To investigate the impact of CuO-ENMs on rheotactic behavior (counter flow swimming), we developed a multi-channel flow chamber which allows simultaneous analysis of different rheotaxis-related parameters: Larvae exposed to CuO (0.5 - 4 mg/L; Calibrate-ENMs) spent less time within the inlet zone of individual channels, their head was orientated against the flow for a shorter duration and their body was bent over 15° for a longer time compared to the controls or low concentrations (0.125, 0.25 mg/L). Overall, rheotaxis (orientation against the stream and avoidance of the stream) was significantly reduced, which is likely due to the release of Cu-Ions. Our data demonstrates that rheotaxis is a particularly sensitive endpoint for behavioral responses to CuO-ENMs and warrants further investigations to understand potential particle-specific effects. This research is performed as part of the EU project “caLIBRAte - Performance testing, calibration and implementation of a next generation system-of-systems Risk Governance Framework for nanomaterials”.

257

Systems toxicology approach for the assessment of imidacloprid neurotoxicity in zebrafish

R. Li, Philip Morris International / UTOX Environmental Toxicology; M. Talikka, Philip Morris International; S. Madan, Fraunhofer Institute for Algorithms and Scientific Computing; J. Doerpinghaus, Fraunhofer Institute for Algorithms and Scientific Computing; A. Zupanic, C.M. vom Berg, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology; J. Szostak, F. Martin, M.C. Peitsch, J. Hoeng, Philip Morris International

Transcriptomic approaches offer a lot of molecular detail and are increasingly being used as part of a chemical toxicity assessment. However, assumptions must be made that the abundance of mRNA corresponds to the abundance and activity of corresponding protein. To address the above limitations we have developed a comprehensive systems toxicology approach to evaluate neurotoxicity in zebrafish larvae. We have chosen the insecticide imidacloprid for this assessment, because if its ability to interfere with the function of the nervous system in fish. Our systems toxicology approach relies on a network model coded in the Biological Expression Language (BEL). BEL is a tool for representing published biological experimental findings in a computable form by coding molecular relationships as BEL statements. We have developed a biological network model describing pathways that lead to neurotoxicity in zebrafish embryos. The network model is composed of 623 observations curated from 90 publications. Biological processes of autophagy, cell cycle regulation, oxidative stress, endocytosis and response to hypoxia have emerged as the major drivers of neurotoxicity in larval zebrafish. Key signaling nodes in the model, such as protein activities, are linked to information about downstream gene expression. Transcriptomic analysis of genes downstream of these nodes can be used to infer activity of the upstream protein – a process termed network scoring. This approach avoids the assumption that mRNA abundance corresponds to protein abundance and activity. Scoring of the network highlights the most affected nodes by a given treatment which leads to mechanistic hypothesis generation and gives a quantifiable measure of network perturbation. Behavioral analysis revealed that zebrafish larvae exposed to imidacloprid move slower in response to light and vibrational stimuli. In agreement with these data, proteomic analysis showed that proteins involved in visual perception and muscle contraction are differentially expressed in exposed individuals. We are now collecting transcriptomic data from zebrafish treated with imidacloprid. These data will be used to score the neurotoxicity network to determine how well the computational model can predict changes measured in behavioral and proteomic experiments. Mechanistic insight gained from computational scoring combined with phenotypical and proteomic analyses provide a comprehensive method for linking molecular events to organ toxicity.

Effect of chronic low doses of ionizing radiation on central nervous system development of zebrafish
S. Murat El Houdigui, IRSN / 13; G. Loro, N. Dubourg, C. Della-Vedova, M. Benadjaoud, C. Adam-Guillermin, O. Armant, IRSN
In the context of an increasing use of radionuclides in medicine, industry and military sectors and after Chernobyl and Fukushima nuclear accidents, the interest for the radiological protection of environment is raising. Some studies have shown an impact of ionizing radiation (IR) on zebrafish development. However, there is limited data on the genetic mechanisms leading to an adverse outcome for early development stages. The goal of this project is to better understand early effects of chronic exposure to low doses of IR on zebrafish development. For that, the study of genetic mechanisms, as well as their consequences on cental nervous sytem (CNS) during zebrafish development was carried out. Fertilized eggs were exposed from the 4-cells stage to the larvae stage in control condition and to two dose rates (5mGy/h and 50mGy/h) of gamma rays emitted by a ^{137}Cs source. The residual radioactive background in the Chernobyl exclusion zone ranges from 0.1µGy/h to 1mGy/h. The effect of IR on embryo development was evaluated by a morphologic analysis, physiological markers measurements and behavior analysis. Together with these macroscopic markers, molecular responses were determined. Gene expression was measured by RNA sequencing. In parallel, these data were validated by RT-qPCR and *in-situ* RNA hybridization. An increase in γ-H2AX foci was found in embryos at 50mGy/h at 24 and 48hpf. Transcriptome analysis was achieved at 24, 48, 96hpf and both dose rates. Among the 35117 zebrafish genes, 782 were found in common between the two dose rates at 24hpf. Among these genes, many were involved in the CNS development. And, a high number of misregulated genes were involved in retinoic acid pathway, a major pathway in embryonic development. An impact on Go Term related to embryo development, neurogenesis, muscle and eye development, heart morphogenesis and hematopoiesis was observed. At 24hpf, embryos perform spontaneous movements controlled by the motor neurons and sensory neurons of spinal cord. This embryonic activity is an integrative parameter of the functioning of a neural network. It is complementary to analyses at the molecular scale. An increase in embryonic activity at 5mGy/h was shown. The transcriptome analysis has shown an impact on some developemental pathways. These genes misregulation are associated with phenotypic disorders such as DNA double-strand breaks, motor and sensory neurons of spinal cord alteration as indicated by embryonic activity.

Life Cycle Impact Assessment (II)

259
A comprehensive assessment of the nutritional and environmental trade-offs of "as consumed" foods
K. Stylianou, University of Michigan / Environmental Health Sciences; V.L. Fulgoni III, Nutrition Impact, LLC; O. Jolliet, University of Michigan / Department of Environmental Health Sciences, School of Public Health
The need for sustainable food choices for the well-being of humanity and the planet is more evident than ever before. However, we currently lack comprehensive metrics that evaluate foods by accounting for both their environmental and nutritional effects. In most food life cycle assessments (LCA), the nutritional value of food is introduced in the functional unit which can be problematic. As nutrition directly affect health, an alternative and more comprehensive method to account for the nutritional value of food in LCAs is to quantify the food's nutritional health impact. This can be achieved by using the DALY Nutritional Index (DANI) as a new impact category in LCA. DANI an epidemiology-based nutritional assessment tool that quantifies the health burden associated with foods in disability adjusted life years (DALYs) based on 16 dietary risk factors. We demonstrated this approach by determining DANI scores for 7,000 food items (48 distinct food categories) in the US diet. The median DANI typically ranged from –56 µDALY/serving (avoided) for health beneficial nuts and seeds, up to 78 µDALY/serving for health-damaging frankfurter sandwiches. We identified the foods with the closest to median DANI score in each of the 48 distinct food categories and determined their life cycle environmental impacts for carbon footprint, particulate matter (PM), water use, and land use. Environmental impacts were established by combining food composition information from the Standard Reference (SR) database (reference flows) and life cycle inventories from Ecoinvent v3.2, World Food LCA Database v3.1, and ESU World food database, and using Impact World+ and accounting for food loss and waste. Carbon footprint estimates ranged from 5 g CO2eq/serving of sugars to 4.2 kg CO2eq/serving meat mixed dishes. PM health burden impacts ranged between 0.007 (sugars) and 2.7 (meat mixed dishes) µDALY/serving, water use between 0.2 (cooked cereals) and 263 (egg/breakfast sandwiches) m3/serving, and land use between 0.004 (sugars) and 3.4 (egg/breakfast sandwiches) ha,yr arable/serving. Comparing the DANI scores with these environmental impact estimates for these foods did not support any correlations suggesting that there is not always a win-win situation. The findings support that there are real trade-offs between environmental and nutritional impacts of foods that must be considered when attempting to establish sustainable diet solutions.

Global site-specific life cycle impact assessment for particulate matter health impacts
C. Oberschelp, ETH Zurich; S. Pfister, S. Hellweg, ETH Zurich / Institute of Environmental Engineering
High spatial resolution becomes increasingly important in life cycle impact assessment (LCIA) where health and environmental impacts depend strongly on the location of emissions. The health impact assessment of Particulate Matter (PM) is such a case, as impacts may change by orders of magnitude based on several site-specific key parameters. Current LCIA approaches distinguish classes of population densities, classes of stack heights and countries of emission as parameters, but generally do not use site-specific factors like wind directions, specific emission heights, specific population densities, emission flow rates, or atmospheric temperatures. Therefore, we present a methodology to calculate site-specific PM characterization factors (CFs) based on modeling of atmospheric pollutant dispersion, quantification of regional pollutant intake and the non-linear effects of PM inhalation on human health. We apply these site-specific CFs to a global site-specific dataset of power plant emissions and compare health impacts against results from non-site-specific approaches. The results show that the site-specific approach reduces uncertainties substantially, helps to direct data collection efforts, and allows to target individual sites for mitigation measures. This is of particular importance as PM is globally the primary cause for pollution impacts on human health.

Development of a H-Phrase scoring method for ecotoxicity characterization
M.H. Lindström, University of Gothenburg; T. Rydberg, IVL Swedish Environmental Research Institute
The work presented here contains the first results of our development of a H-phrase based approach for eco-toxicity characterization. A sample set of substances was derived by gathering relevant substances occurring in the emission inventory from an industrial cluster in Stenungsund [4]. The corresponding environmental H-phrases (H4-phrases) to the substances emitted were found on PubChem Database. Two different models for converting the H-phrases into numerical values were developed. There are seven different codes and corresponding H-phrases, covering acute and chronic toxicity as well as different severity levels (harmful to very toxic). Each substance may have several phrases assigned to it. In both ranking models, chronic phrases were considered more severe than acute ones. For both models the ranking was translated into a logarithmic scale, i.e. the step from one level to the next was set to a factor of 10. The first method was developed by studying all combinations of H4-phrases that the emitted substances had and separating these variations into different levels. A substance with several phrases gets a higher ranking than a substance with only one phrase. Chronic phrases are also ranked higher than acute ones. A substance with several phrases would receive a higher ranking than a substance with only one. The second method differs from the first one in that it only considers the most severe H-phrase in the ranking. When comparing the ranking methods, the second one, which only considers the most severe H-phrase in the ranking is probably the most useful. It has seven set levels and won't fluctuate when the dataset changes. The structure of both methods should be discussed further.The next step in developing this ecotoxicity method that uses H-phrases might be to compare it to and evaluate it alongside strictly effect-based hazard factors, such as EC50 or HC50.

The Effect of Sediment Chemistry on Life Cycle Impact Assessment for Metals
K.J. Farley, Manhattan College / Civil and Environmental Engineering; K.J. Rader, Mutch Associates, LLC; R.F. Carbonaro, Manhattan College; L. Assim, International Copper Association / Health, Environment and Sustainable Development; E. Nordheim, REACH Consultant for European Aluminum; C. Albersammer, International Council on Mining and Metals; C. Bayliss, International Aluminium Institute; A. Vaccari, International Copper Association / Health, Environment and Sustainable Development
The USEtox Life Cycle Impact Assessment (LCIA) modeling approach for freshwater/coastal marine compartments was originally developed to describe the fate and transport of non-polar organic chemicals. For metals, water chemistry (e.g., pH, DOC, competing cations) plays a significant role in determining metal partitioning. Recent research addressed this issue using the Windermere Humic

Aqueous Model (WHAM) to compute water column K_D values based on defined input parameters for freshwater and marine archetypes for use in USEtox LCIA model simulations. However, the effects of sediment chemistry on LCIA has not been considered. The purpose of this study is to evaluate the effects of sediment chemistry on LCIA for metals using the risk assessment screening-level model, TICKET-UWM, to calculate LCIA Comparative Toxicity Potentials (CTPs) directly for freshwater and coastal marine environmental compartments. TICKET-UWM includes simultaneous consideration of dissolved and particulate phase transport between a well-mixed water column and an (oxic or anoxic) sediment layer, along with detailed chemical speciation calculations for metal binding to inorganic ligands, dissolved (DOC) and particulate organic carbon (POC), and Fe/Mn oxide surfaces; precipitation of metal hydroxides, carbonates, and sulfides; and dissolution kinetics for metal concentrates/massives and metal sulfide precipitates. The model also provides a direct evaluation of toxicity using either Free Ion Activity Model (FIAM) or Biotic Ligand Model (BLM) calculations. Critical metal loading rates from TICKET-UWM risk assessment model calculations were translated into LCIA CTPs as: CTP = 0.5 x Average Depth / Critical Load. TICKET-UWM simulations were performed for copper (Cu) and zinc (Zn) using variations in sediment chemistry (pH, sediment POC, redox conditions). The difference in computed CTP for Cu is attributed to the strong sequestration of Cu in sediments by AVS under anoxic conditions. In contrast, redox conditions in sediments had little or no effect on the CTP for Zn. The modeling approach presented above provides a simple method for linking risk assessment models such as TICKET-UWM to LCIA model calculations. The approach allows non-linear responses associated with metal partitioning (in the water column and sediment) to be considered in developing LCIA CTPs for surface waters.

Regionalized terrestrial ecotoxicity assessment of copper-based fungicides applied in viticulture
I. Viveros Santos, CIRAIG - École Polytechnique de Montréal / CIRAIG Department of Chemical Engineering; C. Bulle, CIRAIG - École Polytechnique de Montréal / Strategy & corporate social responsibility; A. Levasseur, Ecole Polytechnique de Montreal / Construction engineering; L. Deschenes, Ecole Polytechnique de Montreal / Genie Chimique
There are some modelling issues related to the application of LCA to agricultural systems. One issue is related to the ways in which the spatial variability of agriculture resulting from soil characteristics, climate and management practices is considered. Another issue is related to the assessment of impact categories whose impact is spatially variable, which is the case of terrestrial ecotoxicity. Emissions of metals in agriculture have been shown to contribute significantly to the ecotoxicity impact, as do copper-based fungicides applied in wine-growing regions to combat downy mildew. The objective of this study is to evaluate the geographical variability of the terrestrial ecotoxicity impact of copper-based fungicides applied in European wine-growing regions. This involves the development of regionalized characterization factors (CFs) for copper terrestrial ecotoxicity, and then the application of these CFs to a regionalized life-cycle inventory that considers different management practices in four different regions, namely Languedoc-Roussillon, Minho, Tuscany, and Galicia. Two methodological approaches were used to derive CFs: (a) empirical regression models, and (b) WHAM 6.0 according to the soil properties of the Harmonized World Soil Database (HWSD). The CFs were then aggregated at different spatial resolutions—global, Europe, country, and wine-growing region—to assess the uncertainty related to spatial variability at different scales and applied in a case study. The global CF computed for copper terrestrial ecotoxicity is around 3.5 orders of magnitude lower than the one from IMPACT 2002+, demonstrating the impact of including metal speciation. For both methods, an increase in the spatial resolution of the CFs translated into a decrease in the spatial variability of the CFs. With the exception of the aggregated CF for Minho at the country level, all the aggregated CFs derived from empirical regression models are greater than the ones derived from the method based on WHAM 6.0 within a range of 0.2 to 1.2 orders of magnitude. CFs derived from empirical regression models showed greater spatial variability with respect to the CFs derived from WHAM 6.0. The ranking of the impact scores of the analyzed scenarios was mainly determined by the amount of copper applied in each wine-growing region. However, finer spatial resolutions led to an impact score with lower uncertainty.

Evaluation of the occurrence and fate of pesticides in the water/sediment interacting compartments of the Ebro River Delta (NE Spain) and risk assessment for aquatic organisms
M. Barbieri, Ins of Environ Assessment&Water Resch (IDAEA-CSIC) / Environmental and Food Chemistry (ENFOCHEM); S. Monllor Alcaraz, Institute of Environmental Assessment and Water Research IDAEA CSIC / Department of Environmental Chemistry; N. Guillem Argiles, Institute of Environmental Assessment and Water Research IDAEA CSIC / Water and Soil Quality Research Group; M. Rambla-Alegre, IRTA Catalan Institute for Research and Technology in Agriculture / Aquaculture Programme; C. Postigo, Institute of Environmental Assessment and Water Research IDAEA CSIC / Environmental Chemistry; M. López de Alda, Institute of Environmental Assessment and Water Research IDAEA-CSIC / Department of Environmental Chemistry
Agriculture is a relevant economic resource worldwide essential to sustain life. However, agricultural activities impact river basins in a way that they contribute to release chemical stressors into the environment, such as pesticides and fertilizers, which may pose a risk for aquatic ecosystems. In this context, the aim of this study was to evaluate the fate of medium and highly polar pesticides in an important wetland area of the Mediterranean region, the Ebro River Delta (NE Spain), to assess the risk that they may eventually pose for aquatic organisms. For this, we investigated the presence of 52 pesticides in water and sediment samples collected in summer, one of the most thriving periods of the rice-growing season. Selected analytes in water samples were determined by means of on-line solid phase extraction-liquid chromatography-tandem mass spectrometry (on-line SPE-LC-MS/MS). In the case of sediment samples, pesticides were extracted by means of pressurized liquid extraction (PLE), followed by extract clean-up with solid phase extraction (SPE), and analysis of the purified extract with LC-MS/MS. Measured concentrations of pesticides were used to evaluate the ecotoxicological risk for aquatic organisms, using the hazard quotient (HQ) approach, and to estimate pesticide adsorption coefficients (Kd). A total of 32 pesticides were detected in water from the Ebro River Delta. Bentazone, followed by propanil and MCPA presented the highest average concentrations (in the µg/L range). Overall, pesticide concentrations were higher in drainage channels than in irrigation ditches, mainly due to a huge presence of bentazone. According to the calculated HQ values, 10 pesticides (azinphos ethyl, bentazone, chlorfenvinphos, chlorpyriphos, diflufenican, irgarol, malathion, oxadiazon, propanil, and triallate) may pose a high risk for aquatic organisms (HQ>10). Concentrations measured in sediments reflect also accumulation of some of the target pesticides in the bed of the drainage and irrigation channels which may also represent an environmental risk. *Acknowledgements-* This work has received funding from the Government of Catalonia (2017 SGR 01404), the Spanish State Research Agency (AEI) and the European Regional Development Fund (ERDF) through the project BECAS (grant number CTM2016-75587-C2-2-R), and the European Union's Horizon 2020 Research and Innovation Programme under grant agreement No. 727450.

Pharmaceutical contamination in a Mediterranean coastal Lagoon: an indicator of complex interactions between societies and wetlands
D. Sadutto, M. Ballester, University of Valencia; Y. Pico, University of Valencia / Environmental Quality and Soil
This field study assesses the occurrence of emerging contaminants (EC) of the Albufera Natural Park. This protected wetland has as an area of 21120 hectares and it is located 10 km to the South of Valencia City (Spain). It consists of a highly eutrophic coastal lagoon surrounded mainly by rice fields that occupy the primitive marshland. The Turia River, to the north, the Jucar River, to the South, and a network of irrigation channels bring fresh water to the Albufera system. The study was focus on about 30 compounds including Personal Care Products and Pharmaceutical Compounds, including acid, basic and neutral. The interest in detecting environmental contaminants in different matrices (mostly water, soil and sediment) is increasing in the last years. This for their relevant impact on the global ecosystem (1). The selected compounds, in this study, constitute an important block of organic contaminants frequently found for many reasons(2). The results evidenced the presence of many of the selected EC both in water and sediment. The most abundant ones are analgesic and anti-inflammatory drugs (salicylic acid, diclofenac), antihypertensive (furosemide), anticoagulant (warfarin), stimulants (caffeine) and preservatives (parabens). The relation-ship between the presence of these compounds and the anthropic pressure in the area was carefully analysed. **References** [1] Blasco (2008), Impact of emergent contaminants in the environment: environmental risk assessment. Analysis of polystyrene microplastics and suspected screening of polymers in environmental samples.
M. Farre, G.F. Schirinzi, IDAEA-CSIC; M. Llorca-Casamayor, IDAEA-CSIC / IDAEA; E. Abad, IDAEA CSIC
This work explores the application of different techniques based on mass spectrometry for the analysis of MPLs. (1) The performance of three different analytical approaches based on mass spectrometry -direct analysis in real time (DART-MS), matrix-assisted laser desorption/ionization coupled to a mass analyser time-of-flight (MALDI-TOF), and HPLC-HRMS will be presented and discussed for the analysis of MPLs; (2) An analytical method based on liquid chromatography coupled to high-resolution mass spectrometry (LC-HRMS) equipped with atmospheric pressure photo-ionisation (APPI) source operating in negative mode has been developed and validated for the analysis of polystyrene in surface and seawater. PS was selected as a representative polymer because it is one of the most frequently used for plastics production;, and separated by 104 m/z. The chromatographic separation was achieved with a gel permeation column (GPC) using toluene 100% as the mobile phase. (3) The use of suspected screening of polymer residues in environmental samples using the capabilities of HRMS has been explored. The different MS techniques will be compared and discussed for the analysis of MPLs. A new method for the quantitative analysis of PS with instrumental limits of detection of 2 pg and a method limit of detection (MLOD) of 100 ng/L will be presented together with the results to their application to the analysis of 15 samples collected in the Ebro River and the marine bays of the Ebro Delta. Finally, the use of retrospective analysis of full-scan chromatograms acquired by HRMS will be discussed and examples of application will be presented. **References** Cole, M.; Lindeque, P.; Halsband, C.; Galloway, S. Evaluation of the adsorption capacity of microplastics in water/sediment systems polluted with persistent organic contaminants
M. Llorca-Casamayor, IDAEA-CSIC / IDAEA; M. Abalos, CSIC / Dioxin Laboratory - Environmental Chemistry Department; E. Abad, M. Farre, IDAEA-CSIC
Microplastics (MPLs), defined as plastic pieces of< 5mm are a recognized environmental problem because their low degradability and, due to their size, they can hamper the oxygen exchange and light leading eutrophication processes. Besides,MPLs can enter into marine food web and, finally, into human diet. MPLs can accumulate persistent organic contaminants and pathogens being also an environmental distributor of these ones. The main objectives of this work were to characterise the sorption capacity of commonly found persistent organic pollutants (POPs) including 7 indicator polychlorinated biphenyls (PCBs) and 18 perfluoroalkyl substances (PFASs) by three different types of microplastics (size between 1 and 300 µm) and to carry out these evaluation mixtures in water/sediment systems. The selected MPLs were high-density polyethylene (HDPE), polystyrene (PS) and Polyethylene Terephthalate (PET) due to their high production and uses, low biodegradability in the environment and their increase as a litter in different aquatic bodies. To assess the capabilities of these MPLs in the aquatic environment, the experimental setup was emulating realistic environmental conditions of freshwater and seawater ecosystems. The results evidenced that MPLs can behave as carriers of selected POPs in marine and surface waters after short exposure time. It can be concluded that MPLs of HDPE, PS and PET can adsorb and stabilise residues of POPs that are present in waters/sediment systems. For the same materials, aged MPLs or/and smaller particles present higher adsorption capacities. In general, the adsorption capacity of MPLs for more polar contaminants studied here were PS > PET > HDPE. The major influence observed for the behaviour are the hydrophobic interaction and salting out effect. Afterwards, the isotherms established for selected pollutants showed that Freundlich model was the most suitable although not all the accomplish this model. Finally, due to the sorption capacity of MPLs for POPs, these should be considered as an extra transport vector for these contaminants in the environment once are adsorbed onto MPL surface'. However, more in deep studies are needed to establish the fugacity factor for MPLs with adsorbed POPs since this is the main parameter that regulates their transferability among environmental compartments. Acknowledgements-This work was supported by the Spanish Ministry of Science,Innovation and Universities through the project PLAS-MED(CTM-2017-9701C3).

Occurrence of metal nanoparticles and fullerene aggregates in wastewater treatment plants, rivers and the littoral zone of Barcelona catchment area
J. Sanchís, IDAEA-CSIC / Water and Soil Quality Research Group; J. Jiménez-Lamana, IPREM, CNRS-UPPA / Laboratoire de Chimie Analytique BioInorganique et Environnement LCABIE; M. Farre, IDAEA- CSIC; J. Szpunar, IPREM, CNRS-UPPA / Laboratoire de Chimie Analytique BioInorganique et Environnement LCABIE
The last decades have witnessed the raise and the popularization of nanotechnology in many scientific disciplines and, nowadays, many types of nanomaterials (NMs) are already being used as additives, catalysts, ultraviolet filters, plastics fillers or bactericides. The commercialization of consumer products containing NMs such as of titanium dioxide nanoparticles (NPs), cerium dioxide NPs, silver NPs, lanthanum oxide NPs or carbon NMs, leads to the potential emission of heterogeneous mixtures of nanostructured materials to the environment. Anthropogenic NPs are known to reach the aquatic ecosystem and mix with the background of NPs that naturally occur in the submicron fraction of suspended particulate matter. Some studies have assessed the environmental levels of *nanowastes* with models and, less frequently, through environmental monitoring exercises [1-3]. Experimental studies commonly face several difficulties, such as the extremely low concentrations of NMs and the need of developing reliable tools for distinguishing between metal-bearing NPs and ionic species. Overall, the presence of NMs in the aquatic environment is still poorly characterized. In the present work, a sampling campaign was carried out in the Barcelona catchment area to assess the presence of selected NMs. 30 freshwater samples were taken in the Besòs River basin and in the Ebro River Delta. Also, 18 wastewater samples and 10 points of the Barcelona littoral were included. The presence of titanium-, cerium-, and silver-bearing NPs was assessed by Single Particle Inductively Coupled Plasma Mass Spectrometry (sp-ICP-MS) and fullerenes were analysed by liquid chromatography coupled to high resolution mass spectrometry with an atmospheric pressure photoionization source (HPLC-APPI-HRMS). Our results show that wastewater treatment plants effectively remove most NPs that are contained in the influents, although a fraction of NPs is finally discharged into the rivers. Levels of NPs in surface water are commonly above the limits of detection, while the vast majority of seawater samples show a non-significant presence of NPs. The observed concentrations of NPs are highly variable along the course of the studied rivers and their natural/anthropogenic origin will be discussed. [1] Gottschalk, Fadri, et al. *Environ. Sci. Technol.* 43.24 (2009): 9216-9222. [2] Sun, Tian Yin, et al. *Environ Pollut.* 185 (2014): 69-76. [3] Bäuerlein, Patrick S., et al. *Sci Total Environ.* 576 (2017): 273-283.

Ascidians (Chordata, Ascidiacea) as model organisms for assessing the extent of anthropogenic pollutants in marine environments
N. Shenkar, Tel-Aviv University / Zoology; D. Avisar, A. Kaplan, Tel-Aviv University / Porter School of the Environment and Earth Sciences; Z. Kuplik, Tel-Aviv University; G. Navon, Tel Aviv University / Zoology; L. Novak, Tel-Aviv University; A. Torfstein, Hebrew University; R. Tzafriri, Tel-Aviv University / Zoology; G. Vered, Tel Aviv University / Department of Zoology
The Mediterranean coastline has been undergoing dramatic changes in the past few decades. Although environmental and governmental agencies invest much effort in general monitoring and protection of this environment, there is a gap in our knowledge of the physiological impacts of current environmental stressors on the marine fauna, and of the possible potential of marine organisms as bio-indicators of environmental health. Sessile marine organisms such as ascidians may provide invaluable information regarding a wide scale of pollutants and stress factors over time, in contrast to common chemical assays. As highly efficient filter feeders, ascidians are well known for their ability to accumulate heavy metals, and to concentrate harmful compounds that are present in low or even only trace concentrations in the water column. The wide geographic distribution of invasive ascidians in both polluted and pristine habitats make them ideal candidates for bio-monitoring a wide variety of marine habitats, and investigating the pathological effects of a variety of stressors. The main objectives of the current study are to explore the potential use of the solitary invasive species *Phallusia nigra*, *Styela plicata*, *Microcosmus exesperatus*, and *Herdmania momus* as biological indicators for micro-plastic, phthalates, heavy metals, and pharmaceuticals. By combining a suit of analytical methods including chemical, physiological, histological and proteomic analysis we aim to locate and describe 'hot-spots' of polluted zones along the Mediterranean and Red Sea coasts of Israel, and further understand the physiological effect of pollutants on benthic invertebrates.

Substitution of Chemicals of Concern: Perspectives and Connections between Analysis of Alternatives, Sustainable Chemistry and Safe-by-design (II)

271
Green chemistry as tool to advance safer solvent substitution
F. Byrne, University of York / Green Chemistry Centre of Excellence, Department of Chemistry; J. Clark, T. Farmer, A. Hunt, J. Sherwood, University of York
Sustainable Solvent Selection is a hot area of research, and it is desperately needed throughout the chemical industry as more and more traditional solvents come under ever increasing legislative strain. Our H2020/BBI project **ReSolve** (2017-2020, grant agreement *745450*) sets out to replace two widely used but hazardous solvents – toluene and NMP (N-methyl-2-pyrrolidone) – with safer

alternatives derived from non-food carbohydrates.[1] New solvents will be designed and modelled with the aim of omitting parts of the molecular structure that are suspected of causing their toxicity, i.e. aromatic groups and amide groups. The best candidates will be synthesised at first on a bench scale, and will subsequently be assessed for their sustainability, scalability, and performance in a wide range of applications. Importantly, solvents will be both modelled for suspected toxicity pre-synthesis, and then tested in a selection of *in vitro* tests. This talk will look in greater detail at two leading candidates currently under further investigation and scale-up. 1) An inherently non-peroxide forming ether solvent, 2,2,5,5-tetramethyloxolane (TMO), has been synthesized from readily available and potentially renewable feedstocks (acetone and acetylene).[2,3] Unlike traditional ethers, its lack of a proton at the α-position to the oxygen of the ether eliminates the potential to form hazardous peroxides whilst also making it suitable as solvent to replace toluene in radically-initiated polymerisations. TMOs boiling point (112 °C), melting point (

272
Substitution and sustainable chemistry: what are key aspects and how to keep the assessment of alternatives fit-for-purpose?
C. Blum, German Environment Agency - UBA / International Chemicals Management; V. Abraham, Ramboll Environ; D. Bunke, Öko-Institut e.V. / Sustainable Products & Material Flows Division; R. Joas, Ramboll Environ
Sustainable chemistry is a holistic approach for sustainable development considering the entire lifecycle of chemicals and their products including design, raw materials, production and processing, application, recycling and end-of-life. Besides health and environment, social conditions, science, research, technical and economic aspects have to be considered and balanced to enable the safe and sustainable use of chemicals within the capacity-limits of our planet. Today's chemicals management has the responsibility to avoid long-term and irreversible damage to human health and environment while at the same time meeting societal demand through economic efficiency. Sustainable chemistry in practice, needs to keep the assessment fit-for-purpose, targeting the elements of importance at a necessary but manageable level of complexity. However, sufficient data of chemicals is needed to provide acceptably information for the actors with the supply chain to decide whether a chemical is able to perform distinct functionalities and contribute to more sustainability at the same time. The German Environment Agency has developed instruments to measure sustainability aspects of chemicals, mixtures, products and services. The instruments addressing important life cycle steps of chemicals beyond (eco-) toxicological risks and hazards to human health and environment, like mobility, resource demand, greenhouse gas emissions, as well as social implications, and economic performance. The Guide on Sustainable Chemicals and the corresponding IT-tool SubSelect are instruments for producers and operators evaluating sustainability through a set of criteria applicable to substances and mixtures. The SMART 5 tool provides criteria to assess characteristics of chemicals applications like human health and environmental properties, workers protection and safe storage, resource consumption, and economic performance. These instruments are already used within industry. We demonstrate in case studies that these tools contribute to interpret the outcome of alternative assessment and lead to successful and sustainable substitution. Thereby, they contribute to a holistic sustainable chemicals management and consequently help producers and operators to green their chemical portfolio, products and services.

From substitution to safe-by-design: towards a safe chemicals innovation agenda
J. van der Waals, Dutch Ministry of Infrastructure and Water Management
Regulations are usually the main driver of substitution of hazardous chemicals, but have drawbacks, such as the time needed to establish hazards and risks, and the costs for industry to adapt existing processes and products. A problem is also that substitutes are often drop-ins that are not necessarily much safer. This points to the need for safe design, where safety aspects (in terms of avoiding damage to human health and the environment) are taken into account at the design stage of chemicals and products. Initiated by the Dutch government, the Safe Chemicals Innovation Agenda was developed as a research agenda to serve as guidance for R&D policies at the EU and Member State level. The agenda and its implementation will be discussed.

Climate Impacts on Polar and Alpine Ecotoxicology and Environmental Chemistry

278
Influence of permafrost disturbances on temporal trends of legacy and emerging persistent organic pollutants in landlocked Arctic char from lakes in the Canadian High Arctic
A. Cabrerizo, Institute of Environmental Assessment and Water Research IDAEA-CSIC; D.C. Muir, Environment and Climate Change Canada / Aquatic Contaminants Research Division; A.O. De Silva, Environment and Climate Change Canada; S. Lamoureux, Queens University / Dept. of Geography and Planning; M. Lafrenière, Queens University / Department of Geography and Planning
Research performed over the past 10 years in the two paired watersheds and lakes (West and East) at the Cape Bounty Arctic Watershed Observatory (CBAWO) has revealed ongoing permafrost disturbances, which are of significant magnitude and importance in West watershed and West Lake even though both catchments are broadly similar. A series of subaqueous slumps over the period 2008-2012 combined with riverine input of suspended solids, particulate organic carbon (POC) and dissolved organic carbon (DOC) from the permafrost disturbances, have resulted in very high turbidity in West Lake. This high turbidity combined with elevated POC and DOC, and other water chemistry parameters, has persisted during 2012-2017 with continued permafrost disturbances in the West Lake watershed. The changes in water chemistry may also apply to inputs and bioavailability of persistent organic pollutants (POPs), associated with the elevated DOC and POC in West Lake compared to nearby East Lake, and to earlier pre-warming conditions. Therefore, our goal was to assess whether these perturbations due to Arctic warming, would affect temporal trends of legacy such as polychlorinated biphenyls (PCBs), organochlorine pesticides (e.g DDTs, HCHs, HCB) and emerging POPs such as perfluoroalkyl substances (PFASs) in landlocked Arctic char (*Salvelinus alpinus*) in the lakes. A comparison with temporal trends of the same pollutants in landlocked Arctic char from other lakes in the Canadian High Arctic was also included.

279
Perfluoroalkyl substances and Organophosphate esters at coastal Antarctica
G. Casas Papell, IDAEA- CSIC / Environmental Chemistry; A. Cabrerizo, IDAEA-CSIC / Department of Environmental Chemistry; A. Martinez-Varela, P. Casal, M. Pizarro, Institute of Environmental Assessment and Water Research IDAEA CSIC; J. Roscales, IQOG-CSIC; E. Cerro-Gálvez, Institute of Environmental Assessment and Water Research; m. vila-costa, Institute of Environmental Assessment and Water Research IDAEACSIC; B. Jimenez, IQOG-CSIC / Department of Instrumental Analysis and Environmental Chemistry; J. Dachs, IDAEA-CSIC / Environmental Chemistry
Persistent organic pollutants (POPs) have long live-times in the environment, accumulate in biota, and have the potential to reach remote regions such as the open oceans and Antarctica. This is especially true for ionizable POPs, such as perfluoroalkyl substances (PFASs) and organophosphates esters (OPEs). Recent work has suggested that PFAS can be transported to Antarctica by atmospheric transport of sea-salt aerosol and subsequent scavenging by snow, overcoming the limited transport by oceanic currents. On the other hand, even though OPEs have been described in the Antarctic Peninsula region, very few measurements of OPEs for surface seawater are available, and there are no measurements of OPEs in plankton. The goal of this study was to determine the presence and the dynamics of PFASs and OPEs, in Antarctic coastal waters. Specific objectives were to evaluate the relative importance of the atmosphere-land-water exchanges as the entry of PFASs and OPEs, focusing on the role of snow deposition and melting as input of these contaminants in Antarctic coastal waters, and the sea surface microlayer amplifying the concentrations of PFAS at the surface ocean. The samples for this study were collected during three different sampling campains at Deception island and Livingston island (South Shetland Archipelago, Antarctic Peninsula). PFAS and OPES surface seawater, snow, SML and plankton samples were pre-concentrated in-situ at the antartic bases, and stored at -20ºC until their analysis in the lab. The analysis of OPES was performed with gas-comatography coupled to mass spectrometry in tandem, while PFAS were analyzed by liquid cromatpgraphy coupled to mass spectrometry in tandem. Seawater from the SML samples had notable differences in concentrations (0.51-3.05 ng L^{-1}) when compared with underlying seawater taken 0.5 m depth (0.03-1.14 ng L-1). Total OPEs ($\sum_{20}$OPEs) concentrations at surface seawater are ranging between 0.6 and 62 ng $L^{-1.}$ In plankton samples, concentrations ($\sum_{13}$OPEs) ranged from 24.80 to 1341 ng g^{-1}. The results show the ubiquity of PFAS and OPEs in the coastal Antarctic ecosystem.

Results will be discussed in terms of the different inputs (oceanic, atmospheric), distance to coast, and role of snow melting amplifying the concentrations. Especially relevant is the demonstration of the amplification of PFAS concentrations in the sea surface microlayer, the implication of which will be discussed.

Pelagic vs coastal - What are the key drivers of pollutants load in Barents Sea polar bears?
P. Blévin, Norwegian Polar Institute; J. Aars, M. Andersen, The Norwegian Polar Institute; M. Blanchet, UiT The Arctic University of Norway; L. Hanssen, NILU Norwegian Institute for Air Research; R. Jeffreys, University of Liverpool; E. Nordøy, UiT The Arctic University of Norway; M. Pinzone, University of Liege; C. De la Vega, University of Liverpool; H. Routti, Norwegian Polar Institute
Barents Sea polar bears exhibit two space-use strategies. The so-called "offshore or pelagic bears" undertaking long annual migrations to follow the ice toward the Eastern part of the Barents Sea and the "coastal bears" staying on land, in Svalbard when the sea ice retreats. Previous studies have highlighted differences in pollution levels with offshore bears generally being more polluted than coastal ones. However, the underlying reasons are currently unknown. It has been proposed that pelagic bears are more active, have greater energy requirements, greater prey intake and thus greater contaminants levels. Alternatively, this may be related to differences in feeding habits, with coastal bears feeding more on less contaminated prey of terrestrial origin and/ or occupying a lower trophic position. Finally, one might expect a pollution spatial gradient related to proximity of source, uptake or transport routes of pollutants. We used activity as a proxy for energy requirements, measured as the duration a bear was in movement. The role of carbon source and diet were investigated by using the isotopic niche ($\delta^{13}C$ and $\delta^{15}N$) as a proxy of the trophic niche. The bear's trophic level was assessed from stable nitrogen isotopes on amino acids ($\delta^{15}N$-AA), using the phenylalanine and glutamic acid as source and trophic amino acids, respectively. Pollutants were also analysed in harp seals from East and West Ice as a proxy for an East-West gradient of pollutants in polar bears food web. Preliminary results suggest carbon source as an important predictor of pollution level. Bears feeding within the marine ecosystem had higher pollutant levels compared to polar bears feeding in terrestrial areas. The trophic niche of coastal bears was much wider compared to the pelagic one, suggesting they are able to target a greater variety of food sources including terrestrial items. Offshore bears may thus be more polluted because of higher proportion of marine preys. Consequently, the trophic niche is likely a key driver of pollution load in pelagic and coastal Barents Sea polar bears. Additionally, PFAS levels were higher in bears using more eastern parts of the Barents Sea and increasing PFAS levels towards East was also observed in harp seals. Finally, activity appears as a minor predictor of pollution load which comes to refute the former hypothesis and thus, energy requirement is likely not a key driver of pollution load in pelagic and coastal Barents Sea polar bears.

Are chemical pollutants influencing the ability of seabirds to respond to changing ice conditions in the Canadian Arctic?
K.J. Fernie, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health; R.J. Letcher, B. Braune, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division; J. Head, McGill University / Natural Resource Sciences; K. Elliott, McGill University / Department of Natural Resource Sciences
Research shows that the exposure of wildlife to chemical pollutants can elicit endocrine disruptive and behavioral effects. Such potential effects may occur in Arctic seabirds that must concurrently deal with rapid environmental changes relating to climate change. Because the endocrine system plays a critical role in allowing animals to respond to environmental stress (e.g., changing ice patterns), endocrine disruption could influence the ability of wildlife to respond to climate change. We are examining such interactions with thick-billed murres (*Uria lomvia*) that feed from ice flows and breed in Hudson Bay, Canada. Reductions in ice result in the birds spending more energy to obtain less fish that may result in poorer reproductive success and chick development. We sought to determine whether a suite of contaminants that bioaccumulates in this species and the influence of climate change have an effect on avian wildlife by limiting their ability to respond to changes in ice availability. In 2016 through 2018, foraging behaviors and movements of > 67 thick-billed murres were tracked with GPS-accelerometers, and concentrations of thyroid hormones, corticosterone, total mercury (THg), a suite of flame retardants (FRs), and per- and poly-fluoroalkyl substances (PFAS) were measured in the plasma of individuals. Levels of all measured PFASs and FRs were consistently low and unrelated to hormones or behavior. However, THg concentrations were associated with circulating triiodothyronine (T3) prior to foraging. In contrast to a "medium-ice" year (2016), in a "low-ice" year (2017), the relationship between T3 and THg was negative. The T3 concentrations of the birds prior to foraging were associated with their foraging behavior; in contrast to 2016, higher levels of T3 were associated with lower diving rates. We found no associations with plasma corticosterone. GPS tracks demonstrated that birds foraged to the north of the colony during incubation when ice was present, then moved to forage to the northwest as chick-rearing progressed when ice was no longer present. These results suggest that birds were foraging near regions of floating ice, which may improve foraging success and reduce diving rates. Based on our 2016-17 findings, we tentatively conclude that THg may influence the ability of these seabirds to adjust to variation in ice cover, and will further examine our hypothesis with 2018 data collected under different environmental conditions. \n \n

Impact of pollution in the Arctic on avian influenza prevalence and miRNA-155 expression in breeding seabirds
C. Waugh, Norwegian University of Science & Technology; M. Lee, S. Strand Lundgren, NTNU The Norwegian University of Science and Technology; G. Gabrielsen, The Norwegian Polar Institute; B. Jenssen, Norwegian University of Science and Technology / Biology; T.M. Ciesielski, Norwegian University of Science and Technology / Department of Biology; . Mortensen, NTNU University / Department of Biology; V. Jaspers, Norwegian University of Science & Technology / Biology
In our rapidly changing, anthropogenically influenced, world, a variety of stressors are affecting the functioningof organisms. One of the most severely affected areas by global change is the Arctic. Major anthropogenic stressors in the Arctic include: 1) climate change, where temperatures are increasing at twice the global rate[1]and 2) pollution, due to long range transport and release from melting ice caps and permafrost; resulting in uncertainty over subsequent effects. One predicted large-scale effect of climate change in the Arctic is the amplification of infectious diseases, due to increased spread[2]. Here, we present the first data that avian influenza virus is now present in the Norwegian Arctic (Svalbard), indicating an extra challenge to the wildlife living there. We further hypothesise that the immunomodulatory properties of many environmental pollutants in the Arctic may facilitate viral prevalence within these historically naÃve populations. Here we present data to support the hypothesis that pollutants can impact disease dynamics in wild birds.We have done sothrough a combination of field and experimental approaches at the molecular (miRNAs) level.ς

Aquatic and Terrestrial Plant Ecology: Ecotoxicology, Risk Assessment and Modelling (II)

284
Experimental studies to provide long-term data sets for testing population models for Lemna sp. and Myriophyllum spicatum
G. Arts, Wageningen Environmental Research (Alterra) / Environmental Risk Assessment; U. Hommen, Fraunhofer IME; E. Bruns, Bayer AG, Division Bayer CropScience / Ecotoxicology; S. Heine, Bayer Ag / Effect modelling; A. Solga, Bayer AG Crop Science Division; S. Taylor, ADAMA Deutschland GmbH
TK-TD (toxicokinetic- toxicodynamic) and population models are considered a promising tool in higher tier risk assessments. Their main merit is lying in their use as a tool in the analysis and prediction of the effects of diverse and dynamic exposure profiles of plant protection products on aquatic organisms. TK-TD models for aquatic macrophytes have been developed and are still being improved. However, long-term datasets are needed for the callibration and validation of these models. These long-term datasets need to cover the growth of the macrophytes over several seasons under realistic environmental conditions. In order to generate such data, a long-term experimental study was set-up in outdoor experimental systems from 2017 to 2019. The growth of *Myriophyllum spicatum* is monitored in a large number of pond baskets installed in an experimental ditch, while the growth of *Lemna* sp. populations is studied in a set of microcosms. The monitoring of biomass (fresh and dry weight) and shoot length or frond numbers is carried out weekly, biweekly or monthly, depending on the season. Apart from the standing crop, seasonal dynamics of recovery growth rates of shoots or fronds over a time frame of 1 month (*Myriophyllum* shoots) or 1 week(*Lemna* fronds) are assessed. In addition, relevant environmental parameters are regularly measured. A high variability in macrophyte growth was observed between replicates over time in both the *Lemna* sp. and the *Myriophyllum spicatum* experiments. The data analysis that will be performed over the next half a year, will focus on answering the question which variables, that have been measured and statistical parameters can be related to this variation. The recovery experiments and the permanently monitored microcosms will probably deliver the best information to the modellers. In the coming months, the datasets will be completed and methods and results will be summarized for the *Lemna* sp. and *Myriophyllum spicatum* experiments 2017 – 2018 (--spring 2019).

Modelling effects of time variable exposure to mixtures of sulfonyl urea herbicides on Lemna
A.J. Jones, FMC Agricultural Solutions / Institute of Environmental Toxicology;

T. Scown, FMC Agricultural Solutions; A. Samel, FMC Corporation / Environmental Sciences; U. Hommen, Fraunhofer IME; J. Klein, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Ecotoxicology
The Tier 1 risk assessment of plant protection products for aquatic macrophytes is usually based on the growth rate inhibition (ErC_{50}) of the duckweed *Lemna sp*. under 7-day constant exposure. In the next Tier, additional species can be tested to reduce species sensitivity uncertainty and/or testing can be conducted under modified exposure regimes to accounty for more realistic exposures (often predicted to be shorter than 7 days). TK-TD models can help extrapolate from the tested exposure regime to the diversity of exposure regimes predicted by the FOCUS surface water modlels. Such models can be used to simulate laboratory tests with time variable exposures, but they can also be coupled with a poulation model to estimate effects on a population in the field of the full FOCUS exposure profile over time. In the project presented here, we used an extensive labaoratory *Lemna sp*. data sets with different sulfonyl urea (SU) herbicides to calibrate and validate a TK-TD model of the growth inhibition. In the next step, validated models for single active substances were combined to predict the effects of plant protection products including two active substances. Laboratory studies with end use products were used to validate the model for the product mixtures. The *Lemna* model used was based on Schmitt et al. (2013). TK-TD is modelled by the use of four parameters, permeability of the cuticula for the given substance, paritition coefficient between water and plant tissue, and ErC_{50} and slope for the logistic concentration response function related to the internal unbound concentration of the active substance. The mixture effect was modelled by introducing a single additional parameter which allows to consider additive, synergistic or antagonistic effects. The *Lemna* TK-TD model could be parameterized to simulate the herbicidal effects of four sulfonyl urea active substances. First analysis indicates that effects of binary mixtures can be modelled under the assumption of concentration addition, which is expected for substances with the same mode of action.

A Multi-model Approach for Increasing Environmental Realism in Risk Assessment for Plants

B. Sackmann, D.V. Preziosi, R.A. Pastorok, Y. Atalay, Integral Consulting Inc.; J. Davies, Syngenta / Environmental Safety; N. Galic, Syngenta Crop Protection Inc. / Environmental Safety
In 2018 the European Food Safety Authority (EFSA) published a Scientific Opinion on the state of the art of Toxicokinetic/Toxicodynamic (TK/TD) effect models for regulatory risk assessment of pesticides for aquatic organisms. The EFSA Scientific Opinion focuses, in part, on a suite of models for primary producers that have been developed over the last decade for algae, *Lemna* and *Myriophyllum*. These models have been used to predict (sub)lethal effects of pesticides under untested (time-variable) exposure conditions and the potential for non-target plant populations to recover from these adverse impacts. While each of these models have the potential to incorporate environmental realism in the form of time-variable flow, temperature, irradiance, and nutrient availability, most experiments and tests of the models, to date, have been done under fixed growth conditions as observed in laboratory settings. Since the performance of these models has not yet been characterized for environmentally realistic scenarios, we adopted a multi-model approach to explore how results from these new models compare and complement results obtained using AQUATOX (https://www.epa.gov/ceam/aquatox). While the equations governing the growth of primary producers in AQUATOX do not include mechanistic formulations of TK/TD, the ability to readily incorporate time-variable environmental forcing functions and ultimately trophic interactions into a well-established model are distinct advantages. As part of the "bridging" across the different models, AQUATOX was first setup to mimic FOCUS scenarios with static environmental conditions, analagous to the setups used for the TK/TD models, and parameterized using the same species-specific biological traits, toxicity data and chemical/physical parameters. These AQUATOX FOCUS scenarios were then extended to assess effects associated with time-variable environmental forcing. AQUATOX simulations were evaluated to ensure that reasonable growth trajectories could be simulated across multiple years for the various primary producers that were modeled. Predictions and results from our combined modelling efforts highlight the unique strengths (and weaknesses) of the various models that were evaluated. Our approach illustrates how a multi-model approach can be used to gain insights into single-species, population-level impacts that are more detailed and comprehensive than can be achieved by using either AQUATOX or an individual TK/TD model in isolation.

Application of functional traits in plant population modelling for chemical risk assessments

P. Rueda-Cediel, University of Minnesota / Ecology, Evolution and Behaviour; R. Brain, Syngenta Crop Protection, Inc. / Environmental Safety; N. Galic, Syngenta Crop Protection LLC / Environmental Safety; V. Forbes, University of Minnesota / Ecology, Evolution & Behavior
The use of population models in herbicide risk assessments for plants is recommended by the scientific community. However, demographic data to parameterize such models are scarce, especially for plant species of conservation concern. Fortunately, existing global repositories of demographic (DT) and functional traits (FT) data are now available. FT are morpho-physio-phenological traits that influence fitness. Several correlations between DT and FT have been identified. In this study, we investigate how such correlations compare across terrestrial plant species of differing conservation concern and use them in the development of a conceptual model for herbicide risk assessments for data-poor species. COMPADRE is an online repository that compiles transition matrices (currently for 664 vascular plant species) that summarize population demography. Likewise, the TRY database compiles FT data (currently for 69000 plant species). We use transition matrices for 213 species to derive different DT. Using the red list from the IUCN we determined the conservation status for these species, of which 50 are threatened. A Welch's ANOVA was performed to explore differences in demography between plant species of different conservation status. Multivariate analyses were performed to explore similarities and differences among species and to explore links between FT and DT. Our preliminary results indicate that there were significant differences in resilience, population growth rate, mean sexual reproduction, specific leaf area, leaf nitrogen and seed mass between threatened plants and plants with no conservation concern. However, plants of conservation concern and plants with no conservation concern did not significantly differ in traits such as longevity, mean life expectancy, survivorship, age at first reproduction, wood density and leaf life. The conceptual model that we developed consists of a generalized plant life cycle with links between DT/vital rates and FT and that links the effects of environmental variability, demographic stochasticity, disturbances (e.g., drougths) and chemical stressors. In conclusion, species of different conservation status differ in some sets of traits but not in others. This suggests that in some cases we may be able to use data from species of no conservation concern to parameterize population models for data-poor species, but that this will need to be carefully assessed to account for differences in other traits.

The GraS model - Simulating the vegetation dynamics for a raster-based landscape

S. Hudjetz, gaiac - Research Institute for Ecosystem Analysis and Assessment / gaiac - Research Institute for Ecosystem Analysis and Assessment; M. Hammers-Wirtz, G. Lennartz, T. Strauss, Research Institute gaiac / gaiac - Research Institute for Ecosystem Analysis and Assessment; A. Toschki, Research Institute gaiac / gaiac - Research Institute for Ecosystem Analysis und Assessment
Environmental risk assessment is currently facing high biodiversity losses and a massive decline of insects in our agricultural and semi-natural landscapes. To address these problems, the landscapes complexity needs to be regarded as a whole, including the impact of multiple stressors. Vegetation dynamics play a key role forming the basis of food webs and providing habitats for animals. Especially semi-natural vegetation elements such as grassy field margins and hedges are of utmost importance, as they e.g. provide nesting sites and food sources throughout the year and are crucial for the resilience and/or recovery of populations. Process-based modelling techniques are recommended to cope with this high complexity on the landscape scale. We here present a dynamic, spatially explicit vegetation model that describes (semi-)natural vegetation dynamics using an individual-based model (IBM) for trees and a compartment model with difference equations for the herb layer. Both submodels work and interact in a spatially explicit, raster-based landscape. Input data for the model consist of spatially explicit GIS data on specific site conditions, the surrounding vegetation, the abundance of ungulates and land use (mowing) of a real landscape. The GraS-Model has been used for management decisions in the Eifel National Park (Germany) and for the management of windthrow areas in Germany. Model testing using space for time substitution showed a good correspondence of modelled and observed vegetation dynamics. The chosen approach was successful in modelling competition of species as well as the impact of land use and herbivory. Site conditions (temperature, moisture, soil pH, nutrients) have been included in the current version of the model. The GraS-Model can be helpful to disentangle and understand the influences of various stressors and to show indirect effects. The model will be developed to include the toxicological effect of herbicides in agriculatural landscapes. Simulated vegetation patterns will be used as a matrix for insect populations in order to understand their reaction to multiple stressors including indirect effects such as the loss of flowers in grassy field margins due to nitrogen input and/or herbicides. With this application, we want to address the urgent question, which management measures should be selected to restore biodiversity or to prevent further biodiversity losses.

The plant community model IBC-grass in ecological risk assessments: A review of recent studies and future applications

J. Reeg, University of Potsdam / Plant Ecology and Nature Conservation; S. Heine, Bayer Ag / Effect modelling; C. Mihan, Bayer AG Crop Science Division / Ecotoxicology; S. McGee, Bayer CropScience LP / Environmental Health Sciences; T.G. Preuss, Bayer AG Crop Science Division / Environmental Safety; T. Schad, Bayer AG Crop Science Division / Environmental Modelling; K. Koerner, F. Jeltsch, University of Potsdam

To assess the impact of herbicide applications on semi-natural habitats like field margins, there is an increased demand on tools to extrapolate individual-level effects measured in standardized greenhouse experiments to population and even community level. Main drawbacks of field studies are their reproducibility, defining a reference community and the lack of standardization. Ecological models are frequently mentioned as suitable tools to bridge the gap between individual-level experiments and the protection goals on community-level as several different environmental scenarios can be covered. The plant community model IBC-grass represents a suitable approach to transfer the individual-level effects into a model community in order to estimate the effects at the plant community level. Several recent studies have explored the potential of using an ecological model in future risk assessments. We will present the results of three studies: The first study validated the plant community for short-term level effects on artificial communities by comparing model predictions to empirical data. The second study aimed at comparing the community-level impact if different (individual-level) plant attributes are impaired by a theoretical herbicide, including reproductive attributes such as seed number. Finally, the third study compared the impact of a theoretical herbicide on three plant communities, which differ in the PFT composition, resource levels and disturbances such as grazing, trampling and cutting. These three studies give a first impression of the potential of IBC-grass to be used in environmental risk assessments. We will also give an outlook on potential future model developments and areas in ecological risk assessment and management for which such a model can be a useful tool.

Complex Mixtures in the Environment: Monitoring, Fingerprinting and Assessment (II)

290
Modelling mixture effects on the estrogen axis using an OECD related biomarker
A. Tindall, Watchfrog S.A.; P. Ferret, Pierre Fabre Dermo Cosmetique; R. Altenburger, UFC Centre for Environmental Research / Bioanalytical Ecotoxicology; M. Scholze, Brunel University London / Institute for the Environment; G.F. Lemkine, Watchfrog S.A.
Over recent decades large numbers of chemicals have been identified as interfering with normal functioning of the estrogen axis. It has become apparent that in order to correctly estimate the risk posed by these chemicals then, in addition to identifying the chemical as endocrine active, two additional elements are required. First, an understanding of the link between the measured effect and a deleterious physiological outcome. This prevents overestimation of risk by taking into account natural variations in signalling as well as homeostatic mechanisms. The second of these elements is an understanding of the effects of multiple chemical stressors acting simultaneously, as in a real-world scenario, compared to the profile of a single chemical during a laboratory study. With this in mind we applied a transgenic medaka fish eleuthero-embryonic model, harbouring the *choriogenin h* promoter driving expression of *gfp*, to the problem of defining mixture relationships. The structural role of choriogenin proteins in egg formation suggests that this biomarker may, like the highly related vitellogenin biomarker, not only reveal estrogen axis activity, but may also accurately predict impaired reproduction. Using more complex exposure protocols this model is also capable of narrowing down the mechanism of action of single chemicals. To explore the possibility of synergistic effects following exposure to binary mixtures, we tested pairs of chemicals exhibiting different mechanisms of action likely to result in synergism. In addition we tested one pair of chemicals consisting of two chemicals with the same mechanism of action, expected to give an additive effect. The selected chemicals included pesticides, pharmaceuticals and a plasticiser, therefore fitting the criteria of realistic mixture components for mimicking exposure of humans and wildlife. The different binary mixtures exhibited predicted, synergistic and anti-synergistic effects when compared to concentration-addition and independent action models. Finally, 12 organic water pollutants exhibiting different mechanisms of action and belonging to a variety of chemical classes were tested individually and in two mixtures with differing component ratios. The experimental observations correlated well with the predicted effects of the mixtures. The ChgH-GFP model has therefore been validated for use in determining the mechanism of action of individual chemicals and the combined effects of complex mixtures.

291
A novel sample preparation procedure for the combined assessment of occurrence and toxicological effects of micro-contaminants of emerging concern in surface waters.
V.F. Osorio, University of Liege; M. Schriks, Vitens N.V.; D. Vughs, P. de Voogt, S. Kools, A. Kolkman, KWR Watercycle Research Institute
Since contaminants of emerging concern (CECs) are present in waters as complex mixtures, target analysis often fails to explain their observed adverse effects on aquatic organisms and human health. Thus, a proper hazard assessment of CECs requires to be addressed by the combination of advanced chemical and bioanalytical tools, as in effect-directed analysis (EDA). A novel sample preparation procedure relying on Solid Phase Extraction (SPE) combining different sorbent materials on a sequential-based cartridge, followed by liquid chromatography coupled to high resolution tandem mass spectrometry (LC-(HR)MS/MS) was optimized and validated for the enrichment of 117 widely diverse (log Kow = [-4-5]) CECs (e.g. pesticides, pharmaceuticals and flame retardants) from surface waters (SW) and further combined chemical and biological analysis on subsequent extracts. A battery of in vitro CALUX bioassays for the assessment of endocrine, metabolic and genotoxic interference and oxidative stress were performed on the same SW extracts. Satisfactory recoveries ([70-130]%) and precision (< 30%) were obtained. Internal standard calibration curves used for quantification of CECs, achieved the linearity criteria ($r2 > 0.99$) over three orders of magnitude. Instrumental detection limits and method quantification limits were of [1-96] pg injected and [0.1-58] ng/L, respectively; while corresponding intra-day and inter-day precision did not exceed 11% and 20%. The developed procedure was applied for the combined chemical and toxicological assessment of SW. Levels of compounds varied from500 ng/L. Artificial sweeteners, industrial chemicals and flame retardants were the most abundant and ubiquitous groups. All SW samples analyzed produced a biological response in one or more of the eight different endpoints measured. Qualitative cause-effect relationships between concentrations of CECs and bioactivity measured in SW extracts were described. The co-occurrence in SW of measured and unknown compounds that might be agonists or antagonists of a certain or multiple bioactivity triggered a complex behavior that could not be disentangled. Thus, further assessment requires to be addressed by an effect-based monitoring combining chemical and bioanalytical tools, as in EDA. Given the demonstrated reliability of the validated sample preparation method, the authors propose its integration in EDA procedures for a proper evaluation of SW chemical and biological quality status.

292
Development of an active air sampling method for the determination of chlorinated paraffins
L. Cioni, University of Florence / Department of Chemistry Ugo Schiff; A. Borgen, NILU-Norwegian Institute for Air Research / Environmental Chemistry; A. Cincinelli, University of Florence / Department of Chemistry Ugo Schiff; N.A. Warner, NILU - Norwegian Institute for Air Research / Environmental Chemistry
Chlorinated Paraffins (CPs) are a complex mixture of industrial chemicals with various applications. This class of chemicals is of increasing concern due to their high production volumes, high persistence/bioaccumulation, and long range transport potential, which puts Arctic environments at risk. However, analysis of CPs is challenging due to their extreme complexity with no established method for their determination, resulting in knowledge gaps about their environmental levels and fate. The aim of this study was the development of a method for the analysis of short-chain CPs (SCCPs) and medium-chain CPs (MCCPs) in air that could be applied to assess long range transport of CPs towards Arctic regions. Using an active air sorbent based sampler previously developed, indoor air samples were collected at various sampling times (4, 8 and 22 hours) to assess optimal solvent extraction volume to elute both SCCPs and MCCPs from sampling cartridges at varying concentration levels. Once optimal extraction volume was determined, outdoor air samples were collected to evaluate repeatability and sorbent breakthrough over different sampling times (24 and 72 hours). Repeatability experiments showed concentrations obtained between parallel samplers were in good agreement for SCCPs with %RSD ranging between 1-15%. However, performance for the MCCPs was poor with %RSD between parallel samplers as high as 70%. For SCCPs, no breakthrough was observed after 72 hours collection, but for MCCPs results of breakthrough experiments were highly variable depending on the experiment. Difference in performance between SCCPs and MCCPs may be attributed to background contamination observed in the field blanks. For SCCPs, blanks were at least 10 times lower than the samples, while blank concentrations for the MCCPs were comparable or higher to concentrations observed in the samples. In addition, field blanks from the same experiments showed comparable concentrations for SCCPs, while for the MCCPs concentrations were highly variable. Blank issues surrounding the MCCPs could be due to contamination during the analytical procedure. Future work will focus on exploring sources of MCCPs contamination to improve the sampler's performace for the determination of MCCPs within air samples.

293
Toxic potentials of air pollutant mixtures and the role of PAHs and their derivatives
Z. Novakova, Masaryk University / Research centre for toxic compounds in the environment; J. Novak, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; Z. Kitanovski, Max Planck Institute for Chemistry; P. Kukucka, P. Pribylova, R. Prokes, Masaryk University / RECETOX; M. Wietzoreck, G. Lammel, Max Planck Institute for Chemistry / Multiphase Chemistry Department; K. Hilscherova, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment
According to the WHO, air pollution represents a major environmental risk to human health and it has been linked to a higher incidence of pulmonary and cardiovascular diseases. Air pollution comprises a complex mixture of both known and unknown chemicals. Therefore, for the toxicity assessment, it is

convenient to employ the battery of *in vitro* bioassays which cover the complexity of such a mixture and can focus on specific molecular mechanisms of toxicity. As for potentially toxic compounds occurring in the outdoor air, polycyclic aromatic hydrocarbons (PAHs) represent an important pollutant group. Even though parental PAHs are widely studied, their derivatives like oxygenated PAHs (OPAHs) or nitrated PAHs (NPAHs), which could significantly contribute to adverse health effects, are frequently ignored. This study aimed to determine levels of 58 PAHs, OPAHs and NPAHs in ambient air as well as to describe several toxic potentials of air pollutant mixtures. Moreover, all results were further investigated with respect to gas/PM partitioning, PM size, pollutant polarity, geographical and seasonal variability and bioavailability from PM. For the purpose of this study, air samples from a heavily polluted urban site and from a background location in the Czech Republic were collected. To assess the more specific distribution of toxic potentials, gas phase, coarse particulate phase, and six PM size sub-fractions were sampled. Moreover, sample extracts were also fractionated according to polarity. Also, certain filter portions were extracted by simulated lung fluids to assess the bioavailability of studied compounds and toxic potentials. Human-based *in vitro* bioassays were employed to study anti-/estrogenicity, anti-/androgenicity, AhR-mediated activity, thyroid receptor-mediated activity and cytotoxicity for respiratory cells. From our results, it can be concluded that air pollutant mixtures possess endocrine disruptive potentials and significant cytotoxicity. Studied effects were observed predominantly in the finest fractions of easily inhaled PM and were mainly elicited by chemicals in the polar fraction. Moreover, significant seasonal variation was detected. Therefore, air pollutants can affect the health of the exposed population via different mechanisms while the contribution of PAHs and their derivatives can explain only part of observed effects. This research was supported by project GACR P503 16-11537S, by RECETOX research infrastructure (LM2015051) and by Max Planck Society.

Analysis of PBDEs and legacy POPs, and PAHs in human breast milk from three Colombian cities
A.C. Torres Moreno, University of Cartagena / FACULTAD DE CIENCIAS EXACTAS Y NATURALES; B. Johnson-Restrepo, University of Cartagena / Chemistry and the Environment Group - School of Exact and Natural Sciences; L. Puente, Universidad de Cartagena / Chemistry and the Environment Group - School of Exact and Natural Sciences; K. Mejia-Grau, University of Cartagena / Environmental and Chemistry Group; G. Codling, Masaryk University / RECETOX; M. Cobo, Universidad de La Sabana; A. Villa, Universidad de Antioquia / Chemical Engineering Department, Faculty of Engineering, Universidad de Antioquia, Medellín, Colombia, 050010; O. Rios-Marquez, University of Antioquia / Departamento de Ingeniería Química; L. Pataquiva-Chauta, Universidad de La Sabana
Polybrominated diphenyl ethers (PBDEs), polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs), and polynuclear aromatic hydrocarbons (PAHs) are contamiants ubiquitous in the environment. All of these compound classes excluding PAHs were generated in relatively large volumes during their period of industrial production and are now subject to long term monitoring and restriction under the United Nations Stockholm Convention on persistant organic pollutants (POPs). Concentrations of seven congeners of polybrominated diphenyl ethers (PBDEs) were reported for first time from Colombia in breast milk (BDE-28, BDE-47, BDE-99, BDE-100, BDE-153, BDE-154 and BDE-183).Thirty-seven polychlorinated biphenyls (PCBs) and fourteen organochlorine pesticides (OCP) were also analyzed in 60 human breast milk samples from volunteering mothers collected in 2015 in three important cities from Colombia (Bogota, Cartagena, Medellin). Most of the investigated PBDE congeners were detectable in the breast milk, ranging in concentrations from 0.13 to 0.78 ng/g lipid wt. BDE-47 congener had the greatest concentration among the samples (Table 1). Overall mean concentrations of OCP oscillated between 0.44 to 6.2 ng/g lipid wt. trans-Chlordan and Endosulfan II were greatest concentrations among OCPs found in the matrix analyzed. On average, Cartagena was the city with the greatest exposure to PBDEs 0.894 ng/g lipid wt, followed by Bogota 0,35 ng/g lipid wt and Medellin 0,338 ng/g lipid wt. Overall mean concentrations of pesticides in the cities was strongly correlated with the mean of PBDEs and OCP concentrations, with averge exposure of 54.0, 364 and 248 ng/g lipid wt for Cartagena, Bogota and Medellin respectively. These results could be related to the city location and diet in each city. Cartagena is the only city located on the Caribbean coast, for instance, the population consume fish more often than the population of Medellin and Bogota. A current study investigating fish from the region of Cartagena may provide insight into local exposure. The results of this study suguest that the concetrations of PBDEs, legacy POP´s and PAHs from Breast Milk in Colombia were present at the concentration as low as countries as US, Japan, and Eurpean countries. This is first study in Colombia to resport different classes of PBDEs, legacy POP´s and PAHs from Breast Milk. ***Acknowledgement.*** Colciencias Grant No. 110759634967

The Environment as a Reactor Determining Fate and Toxicity of Nanomaterials (I)

296
Nanopesticides in the Environment - Understanding their Fate, Bioavailability, Effects and Risks in Soil and Water
J. Hofman, Masaryk University, RECETOX / Faculty of Science, RECETOX; R. Lopez-Cabeza, J. Vašíčková, D. Fojtová, Z. Bílková, Masaryk University / Faculty of Science, RECETOX; R. Grillo, São Paulo State University / Department of Physics and Chemistry, School of Engineering; M. Kah, University of Vienna / Department of Environmental Geosciences
The application of nanopesticides would represent the first intentional diffusive input of engineered nanoparticles into the environment. Yet, knowledge on their environmental fate, behaviour, bioavailability and effects is lacking. Thus, there is an urgent need to increase the fundamental scientific understanding of nanopesticides in the environment. This research is a priority from the perspective of ecosystem and human health and preservation of soil and water quality. On one side, formulation scientists need data how different carrier systems behave in the environment and how they can help designing better pesticide products and optimising the use of pesticides. On other side, risk assessors and regulators need this knowledge to judge between pros and contras of nanoformulated pesticides. Such research is a basis on which nanopesticide regulation and possible commercialization may later be established. This contribution will present the new ongoing research project of RECETOX MU which general goal is to increase understanding of the fate, bioavailability, effects and risks of nanopesticides in environmental matrices. Specific aims of the research are: 1) to adapt, optimize and verify current methods for the study of nanopesticide fate and effects; 2) to increase understanding of factors and mechanisms of nanopesticide fate, behaviour and bioavailability in soil and water; 3) to elucidate the impact of nanoformulation on pesticide toxicity and risks. After the introducing the project and its activities, the results of a pilot case study will be presented. In this study, chlorpyrifos and tebuconazole were added to LUFA 2.1 or LUFA 2.4 soils either as pure active ingredients or as conventional formulations or as nanoformulations (polycaprolactone and solid lipid nanoparticles). Then, the dissipation of pesticides in the soils and their bioaccumulation in earthworms and lettuce were measured over 3 months in simple microcosms. The results showed that the formulation of pesticides significantly affected their fate and bioavailability. Nanoformulation in several cases increased the persistence of the pesticides in soils and bioaccumulation in the earthworms. The uptake to plants was also changed by the nanoformulation but inconsistently (decrease also observed). Studies like this one will be needed in the future frequently to assess environmental pros and contras of the nanopesticides.

Multigenerational exposure of Folsomia candida to copper agrochemicals: conventional and nano-pesticides
J.T. Neves, Department of Biology & CESAM - University of Aveiro / Biology; C.C. Malheiro, Department of Biology, University of Aveiro / Biology; A.R. Silva, University of Aveiro / Dept.of Biology & CESAM; D. Nunes Cardoso, CESAM, University of Aveiro / department of Biology & CESAM; P. Silva, Universidade de Aveiro / Biology Department and CESAM; J. Ulčar, University of Ljubljana / Department of Biology; F. Wrona, Alberta Environment and Parks / Department of Biological Sciences; A.M. Soares, University of Aveiro / department of Biology & CESAM; S. Loureiro, Universidade de Aveiro / Biology
Nanotechnology applications have been growing in agriculture mainly in the form of nanopesticides which are produced to have higher efficacy and therefore to reduce the number and amount of agrochemicals sprays/input to the environment. Copper fungicides are one of the most common pesticides used in conventional and organic agriculture with worldwide application. Already available in the USA market, Cu nanopesticides represent an intentional release of nanoparticles in the ecosystems that raise some concern about their possible impact in the environment. We tried to mimic two realistic agricultural scenarios where we can have a continuous exposure to the agrochemical with aging but also with a contamination coming in pulses. In both cases longer termed exposures are expected for soil populations and communities, and therefore multigenerational exposure and effects are important to assess when looking into a possible impact on the population level. To address this issue we studied the potential toxicity of a multigenerational exposure of copper to collembolan using a conventional pesticide and a nanopesticide, as well as the active ingredient $Cu(OH)_2$ in spiked soil. Survival and reproduction were assessed for three generations using two possible scenarios: 1) Aged soil, where the soil was spiked only at the beginning of the test and, 2) Copper spiking at the start of each cohort. After three generational exposure, the organisms were moved to uncontaminated soil for three extra generations to assess their recovery potential. Exposure to aged soils revealed an increasing tolerance across generations. In contrast, in treatments with freshly spiked soil, the collembolan populations showed ongoing sensitivity. After being moved to clean soil, exposure to copper a.i. and kocide produced prolonged

effects, with no recovery at least after 1 generation in clean soil (e.g. F3). This study emphasises the importance of multigenerational approaches to obtain relevant evaluations of environmental risk associated with chronic exposure to agrochemicals.

Influence of dissolution on the uptake of metal nanoparticles in soil organisms Eisenia fetida

M. Baccaro, Wageningen University / Toxicology Division; M.D. Montaño, Western Washington University / Environmental Sciences; X. Cui, Birmingham University / School of Geography, Earth and Environmental Sciences; H.H. van den Berg, Wageningen University & Research / Division of Toxicology; N. van den Brink, Wageningen University / Dept of Toxicology

The risk assessment of metal nanoparticles (NPs) is challenged by discriminating the uptake of true NPs from released ions in organisms. In soil, metal NPs bioavailability has mainly been attributed to dissolution processes because concentrations of metals in pore water have been correlated to metal accumulation in some soil organisms. However, currently it is still not possible to completely exclude or quantify the uptake of particulate metal. In order to investigate the role that dissolution plays in the uptake of metal NPs in earthworms in natural soil and to reveal any metal uptake in its particulate form, we performed a bioaccumulation test using bimetallic NPs, Au core-Ag shell NPs (Au@Ag-NPs) and combined exposure of Au-NPs, Ag-NPs, Ag and Au ions. The Au core of the Au@Ag-NPs does not dissolve, and would thus behave like an indicator of nano uptake when detected in the organisms because only the outer shell made of Ag would interact with the exposure media. Specimens of Eisenia fetida were exposed to 1.5 mg Au Kg^{-1} and 25 mg Ag Kg^{-1} in different forms of Au and Ag (ionic and/or particulate) in glass jars (n=5) containing natural, uncontaminated soil for 28 days. Au and Ag concentrations were quantified in all the exposure soils and in the organisms by inductively coupled plasma mass spectrometry (ICP-MS). Additionally, the earthworms tissue exposed to Au@Ag-NPs were analysed by inductively coupled plasma time-of-flight mass spectrometry (ICP-TOFMS) allowing to quantify Au@Ag-NPs in their bimetallic particulate form. Metal analysis of earthworm tissue showed that comparison amongst Ag concentrations in the earthworms exposed to the different forms of Ag were not statistically different. However, the concentration of Au in the earthworm tissues exposed to HAuCl4 exceeded twenty times the others which were not statistically different\nreciprocally instead. The co-exposure to both metal ions led to a different uptake pattern compared to the single metal exposure, indicating that important interactions affecting uptake occur in the soil. ICP-TOFMS measurements gave evidence of uptake of the metals in their bimetallic nano form. In this study, it was confirmed that dissolution is the main factor driving the uptake of (dissolving) metal nanoparticles in earthworms. Uptake of non-dissolving particulate is much lower.

Stable isotope tracing of silver nanoparticles in wheat

D. Tarnovska, Centre for Ecology and Hydrology / Department of Earth Science and Engineering; A. Green Etxabe, CEH Wallingford; M. Matzke, Centre for Ecology & Hydrology (NERC) / Molecular Ecotoxicology; T. Junk, Imperial College London; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology; M. Rehkamper, Imperial College London

The rapid development of new products that incorporate silver nanoparticles (Ag NPs), and the subsequent consumer use and disposal of such products, is ultimately associated with the release of Ag nanomaterial (NMs) waste into the environment. Such NMs enter natural ecosystems either by direct release or when Ag NPs discharged into wastewater streams are captured in sewage sludge, which is applied on agricultural land as a biosolid fertiliser. Recent research shows that the impact of Ag NPs on plant cell structures and their physiological and biochemical functions can differ from that induced by exposure to ionic Ag. Due to analytical limitations, such investigations commonly focus on uptake and effects at high and hence environmentally unrealistic concentrations, usually exceeding the predicted environmental levels by three or four orders of magnitude. Stable isotope tracing of NPs can overcome such limitations. This technique employs NPs labelled with a non-radioactive, but highly distinct stable isotope signature, which enables exposure studies with environmentally relevant NP concentrations. In the current investigation, 20 nm-sized citrate-capped ^{109}Ag NPs and dissolved $^{109}AgNO_3$ were added to separate batches of Lufa 2.2 soil to give a final Ag concentration of 72 μg/kg. Winter wheat (*Triticum aestivum L.*) was then grown to maturity under controlled conditions in these soils and plant tissue samples (seed, root, shoot and grain) were taken at eight different growth stages. The concentrations of the two labelled ^{109}Ag forms in the tissues were determined by MC-ICP-MS (multiple collector - inductively coupled plasma mass spectrometry). The analyses revealed that the ^{109}Ag uptake by wheat was higher for the exposure to ^{109}Ag NPs than for the $^{109}AgNO_3$ treatment. The highest ^{109}Ag concentrations were found in the roots exposed to ^{109}Ag NPs, exceeding those found in roots of plants exposed to $^{109}AgNO_3$ by a factor of 3 to 5. No adverse effects on the growth of winter wheat exposed to ^{109}Ag NPs and $^{109}AgNO_3$ at an environmentally relevant Ag concentration of 72 μg/kg were found. **Keywords:** nanoparticles, isotope tracing, wheat

The influence of the plant rhizosphere on the availability of silver nanoparticles to wheat exposed in soil

E. Lahive, Centre for Ecology & Hydrology (NERC); J. Wallis, University of Reading; C.L. Schultz, Centre for Ecology and Hydrology; A. Robinson, Centre for Ecology & Hydrology; R. Sekine, Griffith University; D. Spurgeon, Centre for Ecology & Hydrology; M. Matzke, Centre for Ecology & Hydrology (NERC) / Molecular Ecotoxicology; L. Newbold, A. Oliver, Centre for Ecology Hydrology; S. Harrison, NERC Centre for Ecology and Hydrology / Environmental Contaminants; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology; A. Green Etxabe, CEH Wallingford; E.J. Shaw, University of Reading / Department of Geography and Environmental Science; A. Dudley, University of Reading

Silver nanoparticles (NPs) are expected to reach the soil environment through the application of sewage sludge to agricultural land and will be present predominantly in the form of Ag_2S. Although Ag_2S has often been considered biologically inert, it has been shown that Ag_2S can be taken up by plants and exert toxic effects. Growing plants may affect the behaviour and availability of NPs in soil, particularly the rhizosphere. Plant roots are known to exude organic acids which can impact the pH and organic carbon content of the soil, which in turn may affect the behaviour NPs in the soil. Currently it is not known if and how the plant rhizosphere conditions might influence the availabiltiy of Ag_2S to plants exposed in soil. The aim of this study is to investigate the influence of the plant rhizosphere on the bioavailability of three silver forms (pristine 20 nm Ag NP, Ag_2S NP and $AgNO_3$) to wheat, *Triticum aestivum*. Plants were exposed from seed for 14 days post-emergence in spiked soil. In order to understand how the plant roots may be influencing the availability of Ag in the soil the extractable Ag, pH and dissolved organic carbon (DOC) measured at distances from the plant roots, as well as the concentration in the root, after 7 and 14 days. Significantly higher Ag concentrations were observed in plant roots exposed to 20 nm Ag NP compared to Ag_2S NP and $AgNO_3$. The concentration of Ag in the DTPA extract was highest for the 20 nm Ag NP followed by $AgNO_3$ and Ag_2S NP exposures. There was equivalent accumulation of Ag in wheat exposed to Ag_2S and Ag^+, although there was almost double the amount of DTPA extractable Ag in the Ag^+ spiked soils. The extractable Ag in the Ag_2S spiked soils was consistently lower compared to the other two Ag forms and did not vary significantly with time or with proximity to the plant roots. Overall, this study showed that the extractable Ag in the soil is influenced more by the form of Ag spiked in the soil than by the proximity of the soil to the plant roots. However there was some evidence that soil pH decreased with closer proximity to the roots and there was increased extractable in the $AgNO_3$ exposure in the rhizosphere soil compared to bulk soil after 14 days. This data coupled with information on the structure and diversity of the bacterial and fungal communities provides insights into how the rhizosphere is influencing the bioavailability of different Ag forms in soils.

Toxicokinetics of silver nanoparticles in the plant Brassica rapa

Z. Khodaparast, University of Aveiro / Biology; C. van Gestel, Vrije Universiteit Amsterdam / Ecological Science; R.A. Verweij, Vrije Universiteit Amsterdam / Department of Ecological Science; S. Loureiro, Universidade de Aveiro / Biology

Nanoparticles (NPs) are everywhere and by ongoing applications of AgNPs, the worries about their risks are increasing. Plants as primary producers may especially be exposed to the AgNPs through sewage sludge application onto agricultural land. The aim of this work was to determine the toxicokinetics of several forms of AgNPs in *Brassica rapa*. Lufa 2.2 soil was spiked with 10 mg Ag/kg dry soil of AgNPs 50 nm, AgNPs 3-8 nm, Ag_2S NPs 27 nm and $AgNO_3$. The soil was moistened to 60 % of the maximum water holding capacity. After one day of equilibration, plastic containers filled with 400 g moist soil for each treatment (Ag form) received 8 *Brassica rapa* seeds. After germination of 50% of the seeds, the test went on for another 42 days. At each sampling time (7, 14, 21, 28, 35 and 42 days) three replicates including 2 plants per replicate in the equator of soil were cut from the surface of the soil and the length and the weight of the plant were measured immediately. The different plant parts were separated and dried in an oven. The roots of the sampled plants were carefully washed three times with milli-Q water and dried. The dried plant samples were digested and total Ag content measured by Graphite furnace atomic absorption spectometry. A two-compartment model with two stages in the uptake phase was used to describe the uptake kinetics of Ag in the plants. The *Brassica rapa* plants started to flower usually 11 days after seeding, which is equal to day 7 in our test. So, maybe in the first stage of the growth (before flowering), plants tried to absorb nutrients from the soil as much as they can, possibly leading to a higher uptake of Ag in earlier life stages. In the two-compartment model used, the uptake phase therefore was divided into two stages. Stage I is the time up to day 7 before flowering and stage II is after flowering. The lowest uptake rate constant (K1a), the lowest transfer rate constant (Ki) and the highest elimination rate (K2a) were seen for the Ag_2S NP exposed plants before flowering. After flowering, the root uptake rate constant for AgNPs 50 nm (K1b) was 0.1, while that for other Ag forms was zero which means that the plants exposed to AgNPs 3-8 nm, Ag_2S NPs and Ag^+ stopped Ag uptake and continued to transfer the Ag to the shoot after flowering. The results showed that the distribution of the Ag taken up from the different forms of Ag was different in the exposed plants.

Advances in Soil Ecotoxicology and Risk Assessment - Impact, Ecotoxicity Tests, and Concepts for a Retrospective Environmental Risk Assessment (I)

302
Ecotoxicological tools for precise assessment of phytotoxic effects after soil supplementation with sewage sludge
M. Jaskulak, Czestochowa University of Technology / Faculty of Infrastructure and the Environment; A. Grobelak, Czestochowa University of Technology / Department of Infrastructure and Engineering; M. Kacprzak, Czestochowa University of Technology / Institute of Environmental Engineering; F. Vandenbulcke, LGCgE Universite de Lille
Anthropogenic activities are increasing the contamination of soils with heavy metals that cannot be degraded and hence accumulate in the environment, having the potential to travel through the food chain. Simultaneously, the volumes of produced sewage sludge from wastewater treatment plants are consistently increasing throughout Europe. Their final disposal in agriculture can appear as a viable alternative solution to deal with such a problem. Nevertheless, re-use of sewage sludge can pose severe risks due to their content in contaminants including heavy metals. Hence, re-use must be precisely controlled to minimize the threat to both, the environment and human health. The main aim of the study was to compare and evaluate the sensitivity of different stress markers in plants exposed to soil supplemented with sewage sludge to develop more accurate toxicity tests which can be used across different taxonomic groups and to estimate the impact of sewage sludge land spreading on plants. Moreover, the exposure time needed to produce significant changes was also assessed in order to estimate if the selected markers were not only accurate but also quick to implement. The presented study aims to compare a wide range of potential stress markers in plants species from three taxonomic families: *brassicaceae*, *fabaceae* and *poaceae* after being exposed to soil supplemented with municipal sewage sludge. The tools used to assess the effects of sewage sludge on plants included the germination, biomass, roots length, the activity of antioxidative enzymes, the content of proteins, and chlorophyll, as well as the level of DNA damage and expression of metal chelators – metallothioneins and phytochelatins. Plants were cultivated in a growth chamber for a kinetic between 1 and 28 days of exposure. The dose of sewage sludge corresponded to the EU standards. Presented study showed that the incorporation of ecotoxicological tools in risk assessment of sewage sludge application on soils including the expression of metal chelators and level of DNA damage, allows detection of phytotoxic effects earlier (as soon as 24h of exposure) than with standard toxicity tests. Significant changes started to occur after 7 days from the initial exposure. Moreover, the influence of trace metals in sewage sludge on plants stress response has been assessed measuring the metallothionein coding gene expression in plants exposed to non-contaminated soil supplemented with municipal sewage sludge.

303
Scaling in ecotoxicological assessment of biochar-amended soil: from single-species test to indoor mesocosms experiment
M. Prodana, University of Aveiro & CESAM / Department of Biology; A.C. Bastos, University of Aveiro / Department of Biology Centre for Environmental and Marine Studies CESAM; A.R. Silva, University of Aveiro / Dept.of Biology & CESAM; R. Morgado, University of Aveiro / Department of Biology and CESAM; S. Frankenbach, J. Serôdio, Universidade de Aveiro / Department of Biology and CESAM; A.M. Soares, University of Aveiro / department of Biology & CESAM; S. Loureiro, Universidade de Aveiro / Biology
Application of biochar for soil amelioration and as a carbon sequestration tool is focus of increasing interest, albeit the mechanisms behind its behaviour, ecotoxicity and fate in soil remaining poorly understood. The current study focused on integrative ecotoxicological evaluation of a representative biochar (slow pyrolysis of woodchips, 620ºC), added alone and in combination with compost and mineral fertilizer, through combining the responses of soil organisms and key processes. The study aimed at investigating the effects of the treatments on co-existing edaphic organisms in indoor small-scale terrestrial ecosystem models (STEMs), namely on *Eisenia andrei* survival and body weight, bait-lamina consumption, morphological and production traits of rapid-cycling *Brassica rapa*, and the effects of corresponding leachates on aquatic macrophyte *Lemna minor*. A preliminary screening bioassay was employed to investigate the effects of woodchip biochar on survival and weight changes in *E. andrei*. Statistically significant loss of body weight was observed, and the sub-lethal ecotoxicological parameters LOEC of 5% (w/w) and NOEC of 2% (w/w) were the foundations for the application rate choice in the subsequent mesocosms experiment. In STEMs, the soil was amended with the biochar, biochar-compost, NPK-based mineral fertilizer (0.5 t/ha), and their combinations, at agriculturally relevant application rates of 2% (w/w; equivalent to 40 t/ha). At the end of the 6-week mesocosms experiment, a leaching procedure was conducted on disturbed soil mesocosms. Low-to-no effect on *E. andrei* were revealed. There were no signs of hydric stress, nor treatment-induced effects on photosynthetic activity in plants. Statistically significant stimulation in *B. rapa* seeds number wasobserved, in the biochar-compost combined with mineral fertilizer. Bait-lamina consumption was reduced in the last 12 days in the biochar-amended soil treatment. *L. minor* fresh weight was the most sensitive endpoint, while dry-to-fresh weight ratios were elevated, as response to stress. Biological responses varied from sub-lethal to neutral and/or stimulatory, depending on the test organism, evaluated endpoints, and treatments. Overall, the study results suggest a low risk to soil biota from the application of 40 t/ha woodchip biochar, biochar-compost and their combinations with NPK-fertilizer. Nevertheless, the possibility of nutrients' and/or organic compounds' leaching requires further investigations.

304
Comparative toxicity of parabens on soil species; plant and earthworm
D. Kim, Konkuk University; D. Kim, Konkuk University / Department of Environmental Health Science; L. Kim, Konkuk University; R. Cui, Konkuk University / Department of Enviromental Sciences; Y. An, Konkuk University / Department of Environmental Heath Science
Parabens are added to cosmetics as well as medicines and foods. Therefore, they are likely to be exposed to the environment through use of personal care products. Although they are widely used in the world, there are few studies on soil ecotoxicity of parabens such as methyl-, ethyl-, and propyl paraben. This study assessed the soil ecotoxicity of methyl, ethyl, and propylparaben using plant and earthworm, and compared the toxicity of each paraben. Methylparaben, ethylparaben, and propylparaben were selected as test chemicals, and mung bean (*Vigna radiata*) and earthworm (*Eiseinia andrei*) were used as test species. Earthworm was exposed parabens for 7 days, and mung bean was exposed them for 14 days. Then burrowing rate and growth inhibition was measured as endpoint of each species. The results showed that as the concentration of parabens increased, the number of burrowing individuals decreased as compared to the control group. In the case of mung bean exposed to three parabens, statistically significant effects were observed on the growth measured at 14 days. Through the results of soil ecotoxicity, the toxicity values of three parabens for soil species were calculated. The toxicity of parabens on earthworms were high in order of methyl- < ethyl- < propyl paraben, whereas the effects of parabens on plants were high in the opposite order with the results of earthworm test. In this study, we have confirmed that parabens can affect different species in soil by using plants and earthworms. *This study was funded by the Korea Ministry of Environment (MOE) as the Environmental Health Action Program (1485014458), and the Graduate School of Specialization for managing information of chemical risk.*

305
Characterization of an agricultural soil polluted by As and its impact on plant species diversity and health.
M. LE GUEDARD, LEB AQUITAINE TRANSFERT-ADERA / LEB AQUITAINE TRANSFERT; J. Hellal, BRGM; O. Faure, University of Lyon / UMR CNRS EVS EMSE Géosciences et Environnement; H. Daniel, Bureau de recherches géologiques et minières (BRGM); F.F. Battaglia-Brunet, BRGM / Water, Environment and Ecotechnology Division
Arsenic (As) contamination is a major health issue. 200 million of people in the world are exposed to Arsenic (As) contamination in drinking water. Moreover, accumulation of As by crop plants (rice, barley…) constitute also a risk of exposure to human. Phytoavailability of As and its compound varies among soils and the accumulation of As in plants can lead to toxic effects on growth and productivity. As a consequence, in complement to physicochemical analysis, the phytoavailability of As and its toxic effects need to be taken into account during environmental risk assessment. This study, integrated into the framework of the WaterJPI AgriAs project, investigated the phytoavailability, the phytoxicity of As and the plant species diversity related to the total As content and chemical forms present in an agricultural soil contaminated by the destruction of As-containing shells. The results showed that the As in soils from the site polluted by the destruction of WW1 ammunition is mainly present in the form of AsV and is phytoavailable. The leaf As content increases proportionally with the total As content of soils. According to the results obtained with the biotest using the leaf fatty acid composition of Lactuca sativa (Omega-3 Index), the highest polluted area is the most phytotoxic. Moreover, the Omega-3 Index measured on plant harvested on the site showed that the state of health of some native plant species (B. napus and an Unidentified plant species) seems to be affected on the medium polluted area. The absence of B. napus, P. major and the Unidentified species on the highly polluted area, can be explained by the higth content of As on soil. The state of the health of the only species found on the highly polluted aera (C. arvense and M. chamomilla) does not seem to be impacted by hight level of As even if they accumulate more As. It seems that these plant species set up defense mechanisms for the detoxification of As. These results could explain why no crop plant grown on the highly polluted area when the site was exploited for agriculture and also why only two plant species are found on this area. The implementation of biological tools on this site, in addition to physicochemical analysis, highlights the importance of taking into account the ecological impact in risk assessment.

306
Tackling EFSA recommendations on testing for Ecological Risk Assessment

of Plant Protection Products (PPP) to in-soil organisms

L. Camargo, Universidade do Estado de Santa Catarina; T. Natal da Luz, University of Coimbra / Department of Life Sciences, University of Coimbra; O. Klauberg-Filho, Universidade do Estado de Santa Catarina / Solos e Recursos Naturais; S. Pieper, German Federal Environment Agency (UBA) / Plant Protection Products; J. Sousa, University of Coimbra / Department of Life Sciences University of Coimbra

In the scientific opinion on the risk assessment of plant protection products for in-soil organisms, the Panel on Plant Protection Products of the European Food Safety Authority (EFSA PPR) identifies research gaps and makes recommendations to further improve the current Ecological Risk Assessment (ERA) scheme in-soil organisms. These are e.g. to improve testing and exposure conditions at lower tier, use of Species Sensibility Distribution curves (SSDs) as a potential approach for an intermediate tier and calibrate the assessment factors to attain the protection goal. This contribution aims at tackling these recommendations by presenting data on soil organisms and the insecticide Lorsban 480 (a.i. Chlorpyrifos) as model PPP. At lower tier assessment, EFSA PPR states that the test with predatory mite *Hypoaspis aculeifer* needs amendments regarding more realistic exposure scenarios. By comparing the reproduction of this species when exposed via soil vs. via soil+contaminated prey, it is shown that exposure via food significantly increased toxicity to Chlorpyrifos. Amending the test protocol to include exposure via food will increase its relevance in ERA. As a possible intermediate tier, the use of an SSD approach is proposed, despite the lack of standardized methods for soil species within the same organism group. We demonstrate by testing six microarthropods and six oligochaete species that SSDs are a feasible tools for in-soil ERA, and show that data obtained from tests with the standard species are not always representative for the group sensitivity. Finally, data on a higher tier Terrestrial Model Ecosystem study, using two application scenarios (single application and multiple applications) were performed. Specific effects were recorded, not only according to the traits of the species analyzed (microarthropods and earthworms) but also according to the application scenario adopted. These aspects need to be considered when aiming at a more realistic assessment and calibration of a protective risk assessment scheme for in-soil organisms.

307

Toxicity of imidacloprid and thiacloprid to eight species of soil invertebrates

C. Lima, Vrije Universiteit Amsterdam / Animal Ecology

Since 2013, imidacloprid has its use restricted within the European Union, due to its toxicity to bees. It is also known to be toxic to aquatic invertebrates, but there is a gap in the knowledge concerning its toxicity towards soil invertebrates. Aiming to bridge this gap, this study raised three questions: *(i)* Is there a difference in sensitivity between the taxonomic groups of Annelida and Arthropoda?; *(ii)* Is there a difference in toxicity towards the different endpoints measured (survival and reproduction)? *(iii)* Is there a difference in the toxicity towards different modes of reproduction? Ecotoxicological tests were performed to assess the toxicity of imidacloprid and thiacloprid to *Folsomia candida, Sinella curviseta, Folsomia fimetaria, Heteromurus nitidus, Enchytraeus crypticus, Eisenia andrei*, *Porcellio scaber* and *Oppia nitens*, in Lufa 2.2 soil. Imidacloprid was the most toxic neonicotinoid to all the species tested and to both endpoints. There were no differences in toxicity between the taxonomic groups (Annelids, Arthropods) nor within the different modes of reproduction (parthenogenetic versus sexual), with sensitivity being species specific. The most and least sensitive species to both compounds were arthropods. Within the Annelida, sensitivity of *E. andrei* was more similar to that of the springtails than to *E. crypticus*. It is known for insects that the difference in sensitivity between neonicotinoids can be related to the concentration of different subunits present on the nicotinic acetylcholine receptors. A high concentration of α subunits (high imidacloprid affinity) can indicate a high sensitivity of the species to this compound, and so on (Thany et al. 2006; Tomizawa and Casida 2003). It remains unclear which subunits are present in the species tested. Based on recommended apllication rates, we calculated the PEC of imidacloprid to be 0.03 mg/kg in the top 5 cm soil layer. In earlier laboratory toxicity tests we found a DT_{50} of ~125 days (Lufa 2.2 soil). The application interval sugested for the formulation Confidor is ~7 days, so after 8 applications in one year, the concentration could increase up to ~0.13 mg/kg. This means that the PEC is already within the range of the EC_{10} valuesand could eventually cause some effect on the reproduction of *F. candida*, *S. curviseta* and *F. fimetaria* (0.09-0.12 mg/kg dry soil) or affect the ecosystem services these species provide, such as the decomposition of organic matter.

Bees, Bugs and Beneficials in Environmental Risk Assessment and Testing

308

Do we use plant protection products correctly? Effect of insecticides on the development of the solitary bee Osmia bicornis

J. MOKKAPATI, Institute of Environmental Sciences, Jagiellonian Univeristy / Ecotoxicology and Stress Ecology; A. Bednarska, Polish Academy of Sciences / Institute of Nature Conservation; R. Laskowski, Jagiellonian University / Ecotoxicology & Stress Ecology Group

Solitary bees provide essential pollination services for many arable crops, but are prone to global decline due to intensive agricultural practices such as pesticide usage, posing a major threat to the food security and ecosystem stability. Understanding pesticide toxicity to bees is crucial for protecting pollinator populations, as it may not be possible to cease pesticide usage at the moment because of the growing demand for food. The solitary red mason bee *Osmia bicornis* is regarded as a model organism for pesticide risk assessment but the scarcity of information about effects of pesticides to this species limits its use in pesticide regulation scheme. In this study, the effect of three commonly used insecticide formulations on the development of *O. bicornis* was studied by exposing larvae to insecticide-contaminated multifloral pollen. The insecticides were: Dursban 480 EC, containing the organophosphate insecticide chlorpyrifos (CHP), Sherpa 100 EC, containing the pyrethroid cypermethrin (CYP), and Mospilan 20 SP, containing the neonicotinoid acetamiprid (ACT). At all five tested concentrations of the formulations containing CHP and CYP, significantly lower larval survival was observed with respect to the control ($P \leq 0.01$). Significant decrease in the 18-day larval body mass ($P \leq 0.003$) and cocoon weight ($P \leq 0.02$) further supported the severe influence of CHP and CYP formulations on *O. bicornis* development. Moreover, a significant delay in cocoon formation was observed for CHP-treated larvae ($P=0.008$) but not in the larvae exposed to CYP ($P=0.4$). In contrast, formulation containing ACT did not affect larval survival ($P=0.90$). Also, neither larval body mass nor cocoon weight ($P=0.4$) was affected by ACT and only marginally significant delay in cocoon formation ($P=0.08$) was found. Although the effect found so far in ACT-treated larvae was moderate, the emergence rate of F1 progeny and their later survival rates are still in question. Overall, it is clear from this study that at least some insecticide formulations, here those containing CHP and CYP, affect the development of *O. bicornis* even at concentrations actually found in pollen in the field, indicating an urgent need for revising current pesticide usage recommendations. This study was supported by National Science Centre Poland (grant No. 2015/19/B/NZ8/01939).

Development of a test method for herbivorous lepidopteran larvae

E.G. Padilla Suárez, University of Koblenz-Landau / Natural and Environmental Sciences; C. Bruehl, University of Landau, Institute for Environmental Sciences / Institute for Environmental Sciences; C. Berg, C. Walter, T. Moser, Eurofins Agroscience Services Ecotox GmbH

Currently, the environmental risk assessment of Plant Protection Products (PPP) does not consider the exposure via food ingestion of herbivorous arthropods. Therefore, a prominent route of exposure is not addressed in standard test protocols. To help filling this methodological gap, the testing of lepidopteran larvae was proposed by the EFSA (2015) to represent herbivorous non-target arthropods in eco-toxicological testing, as they play an important role in the ecosystem and are widely distributed across Europe. This study aims to contribute to the environmental risk assessment of PPP, by developing a new test method suitable to assess the potential effects of oral exposure on herbivorous lepidopteran larvae. The development of the test method was divided in three major steps to examine the suitability of the chosen method: 1) the rearing of the species *Vanessa cardui* and *Pieris brassicae* under controlled laboratory conditions 2) the test system development with the key aspects: route of exposure, environmental test conditions, test units, life stage, synchronization, reliability and reproducibility 3) the most relevant and suitable endpoints (e.g. mortality, feeding rate, pupation rate) for the test system considering the mode of action of the pesticide applied. Furthermore, the shortcomings, recommendations and further improvements of the test method will be discussed.

Multi-stress effects on honey bee colonies

C. van Dooremalen, T. Blacquiere, F. van Langevelde, Wageningen University & Research

High losses of honey bee colonies in recent decades are of great societal and economical concern and has been experienced as sign of vulnerability of agriculture, including the service of crop pollination, and of beekeeping. *Varroa destructor* infestation is acknowledged as an important cause of these losses and often suggested to act in concert with contributing stressors, such as or exposure to insecticides, infestation by *Nosema spp.,* or low or monotonous food availability. In several different field experiments, we studied the relative and interactive effects of *V. destructor* infestation and these stressors at field-realistic exposures on the performance and survival of honey bee colonies. Colonies infested by *V. destructor* were 13% smaller in size and were 59.1 times more likely to die than colonies infested with low levels of *V. destructor*, but in contrast to the expectations no interactions with *Nosema spp.* or imidacloprid were found for colony size or survival. Nor did we find a direct effect of imidacloprid on colony size or survival. At individual level in these colonies however, pollen foragers from colonies exposed to *V. destructor* in combination with imidacloprid flew less far (when tethered in a flight mill) compared to colonies exposed to a single stressor. Colonies as a superorganism may well be able to compensate at the colony level for negative effects of stressors on their individuals. In all of our experimental studies under field realistic exposure to stressors, *V. destructor* was by far the most lethal stressor for honeybee colonies.

BEEHAVE validation and resulting insights for the design of field studies with bees
A. Agatz, IBACON GmbH / Ecological Modelling; T. Preuss, Bayer Ag / Environmental Safety
Factors affecting honey bee health are manifold (including diseases, parasites, pesticides, environment and socio economic factors). A lack of standard procedures for higher tier risk assessment of plant protection products for bees and the inability to conduct higher tier studies for all plant protection products, their different use patterns, and at different climatic zones makes coherent availability of data and their interpretation and the use for higher tier risk assessment challenging. Focus has therefore been given to the development of modelling approaches which in the future could fill this gap. BEEHAVE is the first model attempting to link two of the processes vital for the assessment of bee mortality; the within-hive dynamics for honey bee colonies and bee foraging in heterogeneous and dynamic landscapes. Here we show results of several BEEHAVE validation studies conducted. We specifically focusing on insights gathered through these modelling exercises for the design and the usability of field studies for further development, testing and validation of the BEEHAVE model. Overall the model validation shows that predictions of bee hive dynamics fit observations of the total number of adult bees, the total number of offspring in the hive, and the production of drones well. This result underpins the results of the EFSA evaluation of the BEEHAVE model that the most important inhive dynamics are represented and correctly implemented in the model with empirical evidence. Agreement between data and model predictions is particularly high for the initial experimental phase prior the generally conducted relocation of the bee hive from the actual experimental landscape to an overwintering site. Increased discrepancy following the relocation is an artefact of lack of information on the landscape characterisation of the overwintering site for model parameterisation; leading to increased inaccuracy of the model prediction for pollen and nectar resources in the hive, that in turn determines the abundance of bees and thus the overwintering survival probability of the colony. To better assess the suitability of using BEEHAVE for the prediction of bee colony overwintering survival as an important endpoint for higher tier risk assessment for bees it is vital to redistribute experimental efforts allocated to a field study towards a more equal bee hive and landscape investigation throughout the entire experiment, rather than a bias towards the actual exposure phase.

Modelling the impact of insecticides on arthropod populations of agricultural interest
A. Lanzoni, Università di Bologna / Dipartimento di Scienze e Tecnologie Agro-Alimentari; L. Depalo, A. Masetti, E. Pasqualini, G. Burgio, Alma Mater Studiorum University of Bologna / Dipartimento di Scienze e Tecnologie Agro-Alimentari
Mortality and median lethal dose/concentration (LD50/LC50) are used as toxicological endpoints in 95% of published studies in the SELCTV database. Such methods do not provide enough information about the actual effects that may occur in pesticide-exposed populations over periods longer than a few days, resulting in an oversimplification of the potential consequences of pesticide-induced stress. A demographic approach provides better toxicological information than lethal dose estimates We present two case studies where Matrix Population Models (MPMs) are used for assessing the potential impact of insecticides on a beneficial insect - *Adalia bipunctata* (L.) (Coleoptera: Coccinellidae) - in laboratory and for evaluating the resurgence of the two-spotted spider mite - *Teranychus urticae* Koch (Acarina: Tetranychidae) after insecticide application in semi-field conditions. The general model used to simulate population dynamics consists of a matrix containing *i*) survival probabilities and *ii*) fecundities of the population. In both case studies, demography has been used to evaluate the effects of pesticides on populations by means of a Life Table Response Experiments (LTREs). In the first case study exposure of adult stage to fresh residues on leaf surface of rynaxypyr, spirotetramat flonicamid and spinetoram significantly reduced population growth index (λ) in comparison with control. Direct exposure of *A. bipunctata* adults to imidacloprid also produced a significant reduction of λ. LTREs analyses showed very different effects on the vital rates among insecticides. In the second case study the estimated matrices supported the hypothesis that some insecticides, namely ethofenprox, deltamethrin and beta-cyfluthrin, fostered a higher mite population growth than the untreated control. LTREs indicated that the higer population growth was mostly due to increased adult fecundity and egg fertility, thus suggesting a likely trophobiotic effect. Demographic approach showed to be effective to evaluate both lethal and sub-lethal effect of the insecticides either on beneficials and pests. Moreover, LTRE resulted a very sensitive method and pointed out significant differences among insecticides belonging to the same group or sharing the same mode of action. Moreover, we demonstrated that the demographic approach can be extended to semi-field and field studies for the assessment of pesticide effects. Keywords: Matrix Population Models, Ecological risk assessment, Sublethal effects, Spider mites resurgence.

Assessment of toxic reference chemicals of honeybee brood studies under semi-field conditions in Korea
K. Chon, H. Lee, B. Kim, National Institute of Agricultural Sciences; K. Park, National Institute of Agricultural Sciences / Chemical Safety Division; M. Paik, J. Oh, J. Moon, Y. Choi, National Institute of Agricultural Science
Honeybee semi-field tests based on OECD No. 75 were successfully perfomed for 3 years in Korea. Honeybee semi-field tests were carried out to confirm the sensitivity of the method using two reference chemicals (dimethoate and diflubenzuron) in 2016 and to assess the effect of carbaryl wettable powder (WP) and imidacloprid microemulsion (ME) from April to May in 2017 and 2018, respectively. The experiments included three treatment groups (control, toxic reference chemicals (dimethoate and diflubenzuron), and test materials (carbaryl WP and imidacloprid ME), each with three replicate tunnels. The honey bee colonies were introduced in the tunnels with a size of $70m^2$ containing flowering *Brassica napus*. The dimethoate emulsifiable concentrate (EC) 46% and diflubenzuron wettable powder (WP) 25% were used as reference chemicals. The toxic reference treatments were 400 g dimethoate a.i./ha and 600 g, 800g diflubenzuron a.i./ha. The mortality of the honey bees, foraging activity, brood development, and condition of colonies were assessed during the 28 day testing period following BFD 0 (brood area fixing day 0). For the brood assessment, 200 cells containing eggs were selected and evaluated by the computer assisted digital image analysis. The mean brood termination rates (BTRs) ranged from 20.50 to 31.33% in the control group. Treatment with dimethoate and diflubenzuron led to a drastic decrease in the brood development, resulting in BTRs ranging from 68.0 to 100.0% .

Fish Model Species in Human and Environmental Toxicology (III)

Combination of six different zebrafish embryo behaviour assays for neurotoxicity screening
A. Haigis, Institute for Environmental Research RWTH Aachen University; A. Schiwy, RWTH Aachen University Institute for Environmental Research; J. Legradi, VU University; H. Hollert, RWTH Aachen University / Institute for Environmental Research
In the last decade various behaviour assays using zebrafish embryos and larvae were developed, aiming for a fast and easy to use screening tool able to detect neurotoxic substances. Tests like the light/dark transition test, locomotion test or photo motor response (PMR) test were successfully applied by different scientists to identify compounds with potential neurotoxic effects. So far, most studies perform only single behaviour tests a combination of different assays is rarely done.Therefore, this study combined six different zebrafish embryo behaviour assays to screen for neurotoxic effects of 10 pesticides, known to affect organisms, and one spiked environmental extract. The pesticides were tested in four different concentrations in a continuous exposure (until 0-5 days post fertilisation) and the applied behaviour assays were: Spontaneous movement, PMR, locomotion, touch response, thigmotaxis and light/dark transition. The behavioural tests are further validated using biomolecular techniques like the AChE inhibition measurments, transcriptomics and metabolomics.Our aim was to assess the applicability and usefulness/significance of combining all these assays for medium-high through put neurotoxicity screening.Although the PMR is easy to perform its results showed different and inconsistent outcomes, leading to the conclusion that this assay needs further optimisation. The touch response assay was less sensitive than the other tests possibly due to the big variation in behaviour after the touch stimulus. But even with this test embryos with strong effects could be identified. The commonly used tests such as light/dark transition and locomotion were more reproducible and sensitive and seem to be better suited to identify neurotoxic compounds. With the combination of tests more compounds were classified as potentially neurotoxic than when using only single behavioural test. This shows that a combination of tests might be better suited for neurotoxicity screening than single tests. To further improve the use of such a screening approach different exposure times will be investigated to account for the influence of the onset of metabolism on neurotoxic effects. Also, including further tests such as avoidance behaviour could be helpful tools for screening and are therefore considered for further investigation.

315
FISH EXTENDED ONE GENERATION REPRODUCTION TEST: A COMPARISON BETWEEN MEDAKA AND FATEAD MINNOW
T.J. Goodband, Smithers Viscient (ESG) Limited; D. Mitchell, Smithers Viscient (ESG) Ltd
The Medaka Extended One Generation Reproduction Test (MEOGRT) is a standard OECD Test Guideline (No. 240) using multiple generations of fish to generate data relevant to ecological hazard and risk assessment of chemicals. The test evaluates population relevant parameters, such as survival, gross development, growth and reproduction but also includes endpoints which may

provide evidence of endocrine disrupting properties of a chemical such as measuring vitellogenin (Vtg), phenotypic secondary sex characteristics (SSC) and histopathology. The MEOGRT has been designed and validated for use with the Japanese medaka (*Oryzias latipes*). The small size, relatively short life-cycle, easily identifiable phenotypic secondary sex characteristics and genetic sex determination makes *O. latipes* a suitable species for laboratory testing. However, for some potential endocrine affecting chemicals; this may not be the most sensitive, and hence appropriate, species to use for testing. How then can the methodology be best adapted for use with different species and what are the challenges posed? This presentation compares experimental control data for *O. latipes* and fathead minnow (*Pimephales promelas*) showing how the methodology was adapted to achieve a successful outcome and ensure regulatory acceptance and the pros and cons for the use of each species.

Advancing the zebrafish embryo test for endocrine disruptor screening

L. Vergauwen, University of Antwerp / Zebrafishlab Dept Veterinary Sciences & SPHERE Dept Biology; E.D. Michiels, University of Antwerp / Zebrafishlab Dept Veterinary Sciences; A. Van Nuijs, A. Covaci, University of Antwerp / Toxicological Center; S.J. Van Cruchten, University of Antwerp / Applied Veterinary Morphology, Dept Veterinary Sciences; D. Knapen, University of Antwerp / Zebrafishlab Dept Veterinary Sciences

Endocrine disrupting chemicals (EDCs) have been receiving increasing attention in chemical regulations in the European Union. New and improved approaches are needed to meet evolving regulatory requirements worldwide, while at the same time reducing the use of laboratory animals. In this context, the zebrafish embryo offers particular advantages. In this study we provide additional tools and methods to advance the use of the zebrafish embryo for obtaining the required information on ED properties: (1) we explored the use of micro-injection into the yolk of zebrafish embryos as a way to overcome the difficulties related to aquatic exposure to EDCs, which are mostly hydrophobic, (2) we also propose additional endpoints to inform on the ED mode of action. We first compared micro-injection to the traditional aquatic exposure route using five pharmaceuticals with different ED modes of action and observed similarities but also important differences in the responses. We studied these differences in more detail and first focused on toxicokinetics. In both exposure scenarios, internal doses of 17α-ethinyl estradiol (EE2) decreased after 24 hours post fertilization while this was primarily expected after injection, showing the importance of biotransformation and/or elimination in both exposure routes. Next, we observed comparable estrogen receptor (ER) activation after aquatic exposure and injection using a transgenic reporter line, and brain aromatase and vitellogenin (vtg) mRNA levels responded in both scenarios. While vtg protein levels are widely used as a biomarker in adult fish, in embryo-larval stages vtg has so far only been shown to respond to ED at the transcriptional level. Vtg protein levels responded to strong (EE2), moderate (4-tert-octylphenol) and weak (bisphenol A) ER agonists after aquatic exposure. The lower sensitivity of this endpoint seemed to limit the potential to detect vtg alterations after injection. We also observed an increased number of functional hair cells in the developing neuromatsts after exposure to 10 ng/L EE2. While the differences in toxicity between aquatic exposure and micro-injection were mainly observed at high levels of biological organisation, low level markers of ED responded in both exposure routes. Micro-injection could therefore be used for screening hydrophobic chemicals. New endpoints such as vtg protein levels and neuromast development can be used to provide additional information on the ED mode of action.

317

Assessment of the effects of binary mixtures of PAHs on the cardiac function of the rainbow trout (Oncorhynchus mykiss) larva

C. Rigaud, A. Eriksson, E. Vehniäinen, University of Jyvaskyla / Department of Biological and Environmental Science

Fish early life stages (ELS) are among the most sensitive to the developmental toxicity caused by polycyclic aromatic hydrocarbons (PAHs). In addition to the well-documented aryl hydrocarbon receptor (AhR) mediated toxicity of some PAHs such as retene, some weaker AhR agonists like phenanthrene can also produce cardiovascular defects such as arrhythmia via AhR-independent mechanisms. The aim of the present study was to assess the effects of several PAHs, alone or in mixture, on the cardiac function of the rainbow trout (*Oncorhynchus mykiss*) ELS. Newly hatched rainbow trout larvae were exposed for 1, 3 or 7 days to three different individual PAHs, retene (RET), pyrene (PYR) or fluoranthene (FLU), at sublethal doses (3.2, 10 and 32 μg/L for RET and PYR; 5, 50 and 500 μg/L for FLU). Binary exposures to either RET or PYR in combination with FLU were also performed for all tested doses. For each larva, the heart rate (BPM) and the average standard deviation (SD) of the interval (seconds) between each heartbeat were measured. This later parameter was used as an index of the heartbeat regularity. Larvae were scored for deformities (oedemas, haemorrhage and craniofacial deformities) and morphometric parameters such as larval length and yolk sac area were also measured. The heart rate was significantly reduced already after 1 day of exposure at the highest dose of FLU, alone or in combination with the highest dose of PYR. However, the heartbeat regularity was unaffected after 1 day of exposure at any dose and for any compound, alone or in mixture. After 3 and 7 days, the heart rate was significantly reduced at the highest dose of FLU, alone or with any PYR dose. The intermediate dose for FLU also significantly reduced the heart rate at 3 and 7 days, but this effect was almost entirely abolished when combined with the low or medium doses of PYR, suggesting possible non-additive or antagonistic interactions between the two compounds. Heartbeat regularity was significantly altered after 3 and 7 days at the highest dose of FLU, alone or coupled with any PYR dose: larvae exposed to those treatments displayed very clear signs of arrhythmia. The data from the exposure to RET alone or in combination with FLU is still under analysis. The assessment of the expression of several genes (including *cyp1a*) via qPCR in individual larvae is underway, as well as exposures involving binary mixtures of phenanthrene and fluoranthene.

318

Carcinogen Induced High-Throughput Screening Model of Pro-Angiogenesis in Zebrafish Embryo-Larvae

N. Pawar, Jai Research Foundation (JRF) Global / Ecotoxicology; J.R. Rana, D. Patel, Jai Research Foundation / Ecotoxicology; N. Khan, Jai Research Foundation / Chemistry

Tumour angiogenesis is a key target area in cancer drug development. Evaluating the efficacy of novel angiogenic inhibitors require development of suitable animal models in which vasculature can be easily explored. Zebrafish, a vertebrate organism has proved to be a promising model in cancer research. The optical transparency, highly characteristic blood-vessel patterning with short period of development (96 hour post fertilization; hpf) make the zebrafish embryo-larvae best suited for vascular biology studies. Normal vasculature of zebrafish embryo-larvae has been exploited to screen anti-angiogenic compounds. Compared to normal vasculature, tumour induced vasculature shows profound morpho-functional modifications. Accurate efficacy of a drug can be reached by studying its effect on tumour angiogenic or pro-angiogenic model. Engrafting tumour cells into zebrafish embryo-larvae (tumour xenograft) is a widely used technique to trigger angiogenesis. It requires fluorescently labeled human cancer cells, skilled personnel and huge number of tumour xenografts for large scale screening. Treatment with carcinogenic chemical can be an easy and rapid alternate approach to induce pro-angiogenesis. In this study, we used known carcinogenic chemicals, lindane (an organochlorine pesticide) and benzo-a-pyrene (polycyclic aromatic hydrocarbon pollutant). Zebrafish embryos (24 hpf) were exposed to four sub-lethal concentrations for each of the two compounds along with appropriate control. At 96 hpf, the larvae were subjected to whole mount alkaline phosphatase staining allowing microscopic evaluation of two angiogenic parameters [number of sub-intestinal vessels (SIVs) and vessel length]. As compared to the development of normal angiogenic basket formed in the dorsal-lateral part of the yolk in the control larvae, benzo-a-pyrene and lindane exhibited pro-angiogenesis which was evident by their potential to disrupt the angiogenic basket giving rise to outward and internal branching of the vessels. This zebrafish efficacy-toxicity model of pro-angiogenesis can be employed as a high throughput screening tool for dual purpose. Firstly, to screen for pro-angiogenic / carcinogenic potential of compounds, resulting in selection of safer compounds entering the agricultural market as well as cancer risk assessment of harmful pollutants. Secondly, the carcinogen induced pro-angiogenic model can be used to screen for potential anti-angiogenic compounds in cancer drug discovery.

319

CHARACTERISATION AND 3D RECONSTRUCTION OF MELANOMACROPHAGE CENTERS IN SHORTHORN SCULPINS (Myoxocephalus scorpius)

M.T. Dang, Institute for Marine and Antarctic Studies (IMAS), University of Tasmania / Institute for Marine and Antarctic Studies; C. Nowell, Monash University / Drug Discovery Biology, Monash Institute of Pharmaceutical Sciences; T. Nguyen, Nha Trang University / Department of Education and Training; L. Bach, Aarhus University AU Arctic Research Centre / Department of Biosciences; C. Sonne, R.D. Nørregaard, Aarhus University AU Arctic Research Centre / Department of Bioscience; M. Dean, University of Tasmania; B. Nowak, University of Tasmania / Institute for Marine and Antarctic Studies (IMAS)

Melanomacrophage centres (MMCs) are distinct aggregations of pigment-containing cells in internal organs of fish, amphibians and reptiles. Although MMCs are commonly used as biomarkers for anthropogenic exposure in many environmental monitoring programs, a substantial knowledge on characteristics of MMCs is required prior to assess MMC responses. The present study is the first to reconstruct the 3D structure of splenic MMCs of a fish from a number of consecutive sections using the Fiji and AutoCad software. Most splenic MMCs of shorthorn sculpins (*Myoxocephalus scorpius*) had spherical shape and limited variation in size (maximum diameter). We confirmed the close relationship between MMCs and blood vessels in spleen of shorthorn sculpins as 97% of investigated MMCs (60 whole MMCs over 510μm thick of the samples) were closely associated with splenic blood capillaries (mainly ellipsoids) at least once in a set of consecutive sections. It was obvious that the bigger the MMC (maximum diameter) the more likely it would be associated with more and larger blood vessels. In this paper, we provide evidence for the presence and dominance of pheomelamin in MMCs of shorthorn sculpins.

Bio-Based Industries: Sustainability Benefits of Technological Innovation and Closed Loop Approaches across Supply Chains

320
Recycling of biowaste: LCA methodology for different purposes
K. Lyng, Ostfold Research
The circular economy package adopted by the European Union introduces ambitious goals of increasing the amount of material sent to recycling. As the share of source separated biowaste increases, new treatment routes will be formed. To obtain development of sustainable value chains and to ensure reduction of environmental impacts, policy makers and decision makers need information about the environmental impacts of different choices. A comment treatment method of food waste from households and industry is anaerobic digestion, which generates two separate products: biogas and digestate. While biogas may be used to generate heat and electricity or as a fuel for transport if the methane share is increased, digestate can be used as biofertilizer or as compost/soil amendment product. Biogas used as a fuel for transport and digestate used as biofertilizer is identified as the applications that will lead to the largest reduction of environmental impacts in Norway. This application does, however, appear to be the least profitable option for the large scale biogas plants. To obtain the largest reduction of environmental impacts, there is a need for documenting the strengths and weaknesses of the end products, biogas and biofertiliser, in a life cycle perspective. This can stregnthen the market position of the most sustainable products by enableling procurers to perform green procurement by using environmental impact as a criterion when purchasing fuel for transport and fertilisers. Life cycle assessment can be used to evaluate the environmental impacts of products and services in a value chain perspective and can give input to decisions in different contexts. In this study we compare LCA methdology for two purposes for biogas value chains: input to policy development and the use of environmental product declaration in public procurement. The results show major differences in LCA methody for two different purposes.

321
Sustainability check for bio-based technologies: a LCA review
N. Laibach, N. Escobar, Uni Bonn / Institute for Food and Resource Economics ILR
Industries across the world are making a transition to renewable feedstock for the production of organic chemicals, fuels, and materials, as new technologies based on biological principles are becoming increasingly available. However, large-scale bio-based production is not necessarily sustainable if relying solely on traditional biomass sources. Key Enabling Technologies (KETs) are frequently seen as a viable solution to increase resource efficiency and deliver further environmental and economic gains. A systematic review on life cycle assessment (LCA), Life Cycle Costing (LCC) and technoeconomic analysis (TEA) of KETs has been carried out, in order to identify potential impacts from emerging bio-based technologies that foster biomass use and processing. We depart from our own classification developed based on feedstock and, alternatively, on technology, as follows: F1) Crop residues and perennial plants, F2) Designer crops for optimized biomass content, F3) Algae based biomass, FC) Waste or recycled material, C1) Enzyme/microbial assisted processing, C2) Biorefineries. From the systematic search, 31, 2, 13, 33, 46 and 41 publications were obtained for F1, F2, F3, FC, C1 and C2, respectively. Most of them focus on the environmental dimension, showing that there is potential for climate change and non-renewable energy use savings in F1, F3 and C2, as compared with fossil energy carriers, mainly due to co-product credits. Implementing material uses towards integrated biorefineries delivers further gains in F1-F3, although results in terms of other impacts are ambiguous or disadvantageous. Our study shows that the most effective option to improve the environmental performance of bio-based systems is to employ F3 feedstock with C2 conversion technologies, especially in cradle-to-grave or cradle-to-cradle designs. Further harmonization in cut-off criteria for defining the system boundaries is desirable to enhance comparison between KETs in different technological and political contexts. This systematic assessment provides insights on already feasible technological applications for advanced biomass uses, while highlighting options for improvement in the often overestimated sustainability performance.

322
Evaluating the environmental performance of facilitated synergies for producing soil and surfaces through industrial symbiosis
M.A. Martin, IVL Sweden Environmental Research Institute / LCA and Environmental Management
Industrial symbiosis (IS), where different entities collaborate over energy, utilities, materials or services, has been identified as an approach to improve resource efficiency and circularity for industry. This article reviews the environmental performance of an IS network with firms involved in waste management, soil, surfaces, paper, lumber and energy. The aim of this study is to highlight the environmental performance of an IS network and pay particular attention to the value of facilitation services for the firms of the IS network and their products. This is done through the use of life cycle assessment to review the current IS network and compare with a reference scenario and a potential future development. The results suggest that there are significant benefits from the IS network. Large reductions in greenhouse gas (GHG) emissions and local impacts, namely eutrophication and acidification impacts are illustrated. Furthermore, large reductions in abiotic resource depletion were also identified. It was shown that all firms in the network benefit from the synergies involved, with a large share of the benefits stemming from the facilitated exchanges with the waste management company. The replacement of conventional products and energy streams with bio-based counterparts from within the network is of significant importance. Finally, the results point to the importance of the facilitation of by-products and wastes, and the significant value this creates in the region, with large potential to improve the environmental performance of firms and their products.

323
Building Product Fossil, Recycled and Renewable Polymers
M. Vlieg, The Evah Intitute / Vlieg LCA; D. Jones, Ecquate Pty Ltd / The Evah Institute; S. Reiter, Global GreenTag International
Ecologically sustainable development goals are driving technology change and increasing reliance on economical, equitable, recyclable and renewable supply chains for circular economies. Key environmental pressures include global scale climate change, litter killing wildlife and pollution contaminating supply chains. In response, industry innovation and technological transformations are enabling conversion of traditional fossil, recyclable and renewable energy and feedstocks into improved and new products. Normal post-consumer (PC) recycled and biomass plastics are now in increasingly high demand. This study compares life cycle inventory, impact and benefit assessment of fossil Polyethylene Terephthalate (PET), PC recycled PET, and corn-based polyactide (PLA) used in building products e.g. insulation, reinforcing fibres, fitout materials and fabrics for production systems in America, Europe and the Pacific Rim. It compares water, feedstock and energy use outcomes of competing recycled, renewable and fossil feedstock cohorts. Land-use change and ensuing global warming potential of emissions are also discussed. The study reviews the authors' cradle to grave case studies of Pacific Rim sourced PC recycled PET building products, NatureWorks study of PLA and PET background data from PlasticsEurope. All data are from primary producers and manufacturers. Although PLA may be the preferable option for some (building) products, there are certain properties that may limit its use in certain building applications such as in-wall insulation. PLA's biodegradable and compostable properties make it less suitable for long-term used products as in-wall insulation products. PLA was also found less suitable for packaging of insulation material than PET, as the tensile strength of PLA is lower. The pigmentation use and percentage of renewable energy in the grid can be of great influence on the Life Cycle Impacts of the three studied materials.

324
EPDs for Wooden Average Data Construction Products
T. Räty, Natural Resources Institute Finland (Luke); T. Sinkko, EU Commission Joint Research; M. Jallinoja, Natural Resources Institute Finland Luke
The EN 15804:2012+A1:2013 compatible Environmental Product Declarations (EPDs) have been gradually introduced in several countries, in Finland since 2016, ensuring a platform for commensurable assessment of construction products. In this paper we discuss on problems that arise concerning wooden average data construction products. They are especially useful for the micro and small enterprises, to whom the value of own EPD is beyond economy. In our case, the first example is the laminated log wall structure and the second case is LÄHIPUU® (Local Wood) lumber. According the standard, average data shall be derived from specific production processes. The EPD is calculated using producer weighted averages. However, there are no clear rules how the variation due to the sample should be communicated. In our case we have chosen the standard error of the mean (SE). The practicality of SE is that the 95 % confidence interval for the estimated impacts is roughly within two times the SE. EN 15804 compatible EPD are based on modules. The minimum requirement are A1-A3 (product stages), A4-A5 (construction) and C3-C4 (EoL). Additional benefits can be reported in module D. It is also possible to include carbon stock in the module A1-A3, but its treatment (release) should be included in C3-C4. Substitution gains from energy use of demolished wood can be reported in module D. The declared unit for the cases 1 m^3 of laminated log and 1 m^3 sawn and dried lumber. Altogether 5 log house factories were inventoried, presenting production of 16 members of the Finnish Log house Industry Association. LÄHIPUU® is the trademark of Finnish Small Sawmills Association with approximately 240 members. Three production alternatives were modelled. Tractor powered mobile sawmill (9 members), and fixed sawmills with sun dried lumber (4 members) and 5 members with kiln drying facility. For the time being, specific data of the Finnish modern forest management and harvesting is not available, but the standard allows generic data to be used for A1, albeit it can be an important source of uncertainty. The generic data set for roundwood induces 12% to 48% of the EPD's impacts. As the present data set is valid but rough, urgent revision is needed to ensure credibility of Nordic wood product EPDs. Variation between average product's producers

appears not to be that large as one could have *ex ante* expected. Special effort should be put on how to communicate on avoided GHG emissions and carbon stock

Understanding the Complexity of the Natural Aquatic Environment Facing Global Changes

326
Influence of water flow and light availability on intracellular biofilm geosmin formation
C. Espinosa, M. Abril, J. Colon, Universitat de Vic Universitat Central de Catalunya / BETA Technological Centre; H. Guasch, University of Girona / Institute of Aquatic Ecology; S. Ponsá, L. Proia, Universitat de Vic Universitat Central de Catalunya / BETA Technological Centre; N. Pou, Universitat de Girona / GRECO; M. Ricart, Universitat de Vic Universitat Central de Catalunya / BETA Technological Centre; N. Sellarès, Universitat de Vic Universitat Central de Catalunya / Centre dEstudis dels Rius Mediterranis; M. Ordeix, Universitat de Vic Universitat Central de Catalunya / Centre de Estudis dels Rius Mediterranis; L. Llenas, Universitat de Vic Universitat Central de Catalunya / BETA Technological Centre
Global climate models have predicted that changes in mean values and increased variance in amplitude of climatic parameters will inevitably lead to more frequent and more intense extreme events. Alterations in flow regime are expected to severely affect freshwater ecosystems in several regions e.g. the Mediterranean. In addition to environmental factors, flow can also be affected by anthropogenic factors, such as dams. Human activities can also affect river banks causing riparian forest modifications and consequentially altering the quantity and quality of light potentially reaching riverbed. Environmental or anthropogenic variation of light and/or flow regimes accounts for much of the variation in the physiology, population growth, community structure and functioning of benthic microbial communities. Some of these alterations are associated with the appearance of tasty and odorous compounds in river waters. Among others, geosmin is a metabolite produced mainly by cyanobacteria associated to benthic biofilms. The environmental and anthropogenic factors associated with its production are still not clear. For this reason, geosmin episodes, in freshwater ecosystems exploited for drinking purposes, still suppose an economic problem for the water supply companies since they cannot predict its appearance. This study aimed to evaluate, under controlled conditions, the effects of water flow and light availability on biofilm structural and functional development, and intracellular geosmin occurrence. We performed a 6 weeks mesocosm experiment in late winter – early spring. The mesocosms were a set of 10 outdoor 3m long flumes receiving water continuously from the Ter River (Catalonia, NE Spain). Five gradually increasing flows from 0.02 to 0.16 m/s were set and combined with two light intensities: full natural light and reduced by 80%. Water samples were taken to analyse nutrients uptake. Biofilm samples were taken to analyse geosmin concentration, chlorophyll a content and the community. The results obtained shows how the nutrients uptake varies depending on flow and irradiance. It has also been shown that the interaction of lower velocities with low irradiance favours the growth of benthic *Oscillatoria* sp., and that under these conditions it can produce geosmin, a metabolite that once released into the water generates a bad taste and odour to it provoking serious issues to drinking water companies and consumers.

327
Integrating daily temperature variation and life stages when assessing the reciprocal impact of sensitivities to a pesticide and to climate change
V. Delnat, T.T. Tran, J. Verheyen, L. Janssens, R. Stoks, KU Leuven / Biology
Because of failing risk assessment and global climate change there is increasing attention for the reciprocal effects between climate change and pollutants to improve risk assessment. Two important and connected topics have been largely ignored in this context: (i) the role of daily temperature variation (DTV) as a key component of climate change, and (ii) differences in sensitivity to climate change and pollutants between larvae and adults. We investigated whether DTV magnified the negative effects of the organophosphate pesticide chlorpyrifos (CPF) on mortality and heat tolerance and whether this effect was stronger in aquatic larvae than in terrestrial adults of the vector mosquito *Culex pipiens*. Exposure to CPF imposed mortality and reduced the heat tolerance (measured as CTmax) in both life stages, which is consistent with the TICS concept ("toxicant-induced climate change sensitivity"). Notably, larvae were more sensitive to CPF than adults both in terms of mortality and in reduction of heat tolerance (CTmax), highlighting the life-stage specificity of the TICS concept. While DTV had no direct negative effects, it magnified the toxicity of the pesticide in terms of larval mortality, which is consistent with the CITS concept ("climate-induced toxicant sensitivity"). Moreover, DTV caused a stronger CPF-induced reduction in heat tolerance of adult females, thereby illustrating the coupling of both concepts and providing support for the reciprocal effects between climate change (here DTV) and pollutants. Taken together, our results highlight the importance of integrating DTV and life-stage specificity to improve risk assessment of pollutants under climate change.

328
Does water scarcity influence the impact of anthropogenic stress on aquatic invertebrate assemblages?
A.A. Sanchez, A. Rico, IMDEA Water Institute / Aquatic Ecotoxicology; S. Dolédec, LEHNA / Biodiversité et Plasticité dans les Hydrosystèmes; M. Vighi, IMDEA Water Institute / Earth and Environmental Sciences
Combined effects of chemical pollution and water scarcity are one of the most important threats to aquatic ecosystems in (semi-)arid regions of the world. The low dilution potential in aquatic ecosystems receiving wastewaters can enhance chemical exposure, leading to devastating direct and indirect toxic effects. The main objective of this study was to assess the combined effects of pollutants related to anthropogenic impact on aquatic ecosystems in scenarios of water scarcity. In particular, we evaluated the response of aquatic invertebrates in the semi-arid region of Madrid (Central Spain) based on the taxonomic and functional variation of communities exposed to chemical pollution associated to anthropogenic impact, and additionally, to water scarcity. Twelve sites were selected in the watershed of the Tagus river and sampled at three seasons (spring, summer, fall) covering a gradient of anthropogenic impact and hydrological stress. Water quality was assessed by measuring physico-chemical parameters (pH, T, conductivity, DO, DOC, nutrients), metals and organic microcontaminants in water. At each site, the macroinvertebrate community was sampled with a Surber net in triplicate along a river transect. We used univariate and multivariate statistical techniques to evaluate how anthtopogenic and hydrological stressors may affect the invertebrate communities, and the relative utilization of biological traits. Environmental variables did not show clear seasonal patterns, but significant differences were identified between groups of sites with different anthropogenic impact and hydrological condition. Highly impacted sites with low hydrological stress were characterized by high TUs, nitrites and phosphate whereas highly impacted sites with high hydrological stress had also high conductivity and suspended solid fluctuations. Moreover, despite that the environmental data did not show a clear seasonality, biological responses acted as an integrative indicator of anthropogenic and hydrological stress (mostly in summer and early fall) in terms of taxonomic and functional composition. Hydrological stress mainly influenced reproduction and feeding types. This study proves that hydrological and anthropogenic stress interact to affect macroinvertebrate communities. The interaction between these stressors should be taken into account in further updates on the ecological status assessment of surface waters.

329
Effects of S-metolachlor and terbuthylazine in the biochemical profile of the estuarine species Scrobicularia plana
I.B. Gutiérrez, MARE -Marine and Environmental Sciences Centre, Department of Life Sciences, Faculty of Sciences and Technology University of Coimbra / Department of Life Sciences of University of Coimbra; A.d. Mesquita, Department of Biology & CESAM - University of Aveiro / Department of Biology and CESAM; C. Nunes, CICECO - Aveiro Institute of Materials & QOPNA Department of Chemistry, University of Aveiro / Department of Chemistry CICECO; M.A. Coimbra, CICECO - Aveiro Institute of Materials, Department of Chemistry, University of Aveiro / Department of Chemistry CICECO; F.J. Gonçalves, University of Aveiro / department of Biology & CESAM; J.C. Marques, MARE - Marine and Environmental Sciences Centre, Dep. of Life Sciences, Faculty of Sciences and Technology, University of Coimbra / MARE, Dep. of Life Sciences, Coimbra University; A. Gonçalves, MARE - Marine and Environmental Sciences Centre, Department of Life Sciences, Faculty of Sciences and Technology, University of Coimbra & Dep. of Biology and CESAM, University of Aveiro / MARE (Marine and Environmental Sciences Centre), Department of Life Sciences, Faculty of Sciences and Technology / Dep. of Biology and CESAM
This study highlights the impacts of S-metolachlor (SMOC) and terbuthylazine (TBA) in the biochemical profile of *S. plana*. SMOC and TBA are active ingredients (a.i.) in several common herbicides, such as Primextra® Gold TZ, the most used in the farmlands that surround the Mondego estuary, in the coast of Portugal. The overuse of pesticides leads to contaminations in aquatic systems, affecting non-target species. *S. plana* was selected due to its key position in trophic webs, linking primary producers and consumers. Bioassays were performed exposing *S. plana* to a range of concentrations of each chemical for 96h. Fatty acids (FA) and carbohydrate composition were analysed in the survival organisms. Moreover, the analyses were performed in two types of tissues - the muscle and visceral mass of each organism. Muscle presents higher saturated fatty acids (C18:0, C20:0, C23:0 and C24:0) and unsaturated fatty acids (C22:1, C24:1n9, C22:2 and DHA) than visceral mass. Thus, muscle shows to be the most cost-effective tissue to detect the presence of SMOC and TBA in aquatic environments. Organisms exposed to SMOC present low highly unsaturated FA whereas organisms exposed to TBA showed low levels of monounsaturated FA

and polyunsaturated FA. In general, TBA exposure resulted in lower nutritious quality in terms of FA content and diversity than SMOC exposure. Similar changes have been reported in aquatic primary producers exposed to Primextra, thus, there is a risk of low occurrence of FA in aquatic environments exposed to this pollutant. Glucose is the only carbohydrate found in *S. plana*, expectable since glycogen is the main polysaccharide in animal tissues. Glucose content increase under chemical exposure. The sugar analyses also reported a decrease of glycogen. The present work presents tools to predict the presence of SMOC and TBA in aquatic systems and to go deeper at the knowledge of their biochemical impacts in non-target species and its propagation through aquatic trophic webs to the entire environment. FCT supported the study through the strategic projects UID/AMB/50017/2013, UID/MAR/04292/2013,UID/CTM/50011/2013 and POCI-01-0145-FEDER-007679, UID/QUI/00062/2013 granted to CESAM, MARE, CICECO-Aveiro Institute of Materials, and QOPNA, respectively. FCT funded A.F.C. Mesquita, A.M.M. Gonçalves and C. Nunes by doctoral (SFRH/BD/139831/2018) and post-doctoral (SFRH/BPD/97210/2013 and SFRH/BPD/100627/2014) grants, respectively.

Copepod respiration at combined exposure to predation risk and copper

T. Lode, University of Oslo / Department of Biosciences; J. Heuschele, University of Oslo / Section for Aquatic Biology and Toxicology; T. Andersen, J. Titelman, K. Hylland, University of Oslo / Department of Biosciences; K. Borga, Department of Bioscences, University of Oslo / Department of Biosciences

Predation risk can potentiate copper (Cu) toxicity in copepod age at maturity. One suggested explanation is that predation risk synergistically interacts with anthropogenic stressors through increased metabolic demands and nutrient limitation. To identify the underlying processes of the potentiated Cu toxicity, we examined the combined effects of predation risk and Cu on copepod respiration. We used the harpacticoid copepod *Tigriopus brevicornis* as our model species. Adults individuals were incubated individually in OxoDish OD24 wellplates, and exposed for 15 hours to one of the treatments predation risk, Cu (20 $\mu g\ L^{-1}$), combined predation risk and Cu (20 $\mu g\ L^{-1}$), or control. Predation risk was simulated by exposing the copepods to water containing three-spined stickleback kairomones (i.e. chemical cues). We measured copepod respiration continuously while incubated using SDR SensorDish® Readers.. We also examined differences in respiration among males, females and pregnant females (i.e. females with egg sac). After terminating the experiment, individuals were photographed for subsequent length measurements. Preliminary results suggest that both predation risk and Cu increase respiration during single exposure, and effects are less than additive when combined. Nor are any respiration differences observed among males, females and pregnant females. We additionally examined if spawning rates or egg-emergence among females varied according to treatment, however, no patterns were evident from the results. Our results as presented here are preliminary and should be interpreted accordingly. While both stressors seemingly increase respiration, it does not seem to explain the potentiating effect of predation risk on Cu toxicity in copepod age at maturity.

331

Response variability to multiple stressors exposure in wild fish: biological level and populations matter

Q. Petitjean, Laboratoire EcoLab, Ecologie Fonctionnelle et Environnement (UMR5245 CNRS-Université de Toulouse); L. JACQUIN, Laboratoire Evolution et Diversité Biologique, UMR5174 EDB, Université de Toulouse, CNRS, IRD, UPS, 118 route de Narbonne, 31062 Toulouse, France.; A. PERRAULT, M. COUSSEAU, P. LAFFAILLE, S. JEAN, Laboratoire Ecologie Fonctionnelle et Environnement, UMR5245 Ecolab, Université de Toulouse, CNRS, INPT, UPS, 118 Route de Narbonne, 31062 Toulouse, France.

Aquatic organisms face multiple challenges in human-altered rivers such as abiotic (e.g. contamination) and biotic (e.g pathogens) stressors. Defense mechanisms against these stressors are likely to interact strongly but their interacting effects are still understudied, hindering our ability to predict the responses of wild populations to multiple stressors. Recent studies bring very variable results depending on the populations and biological level of organization considered. In this study we tested: i) how an experimental exposure to trace metals could affect the response (immunity, bioaccumulation, energy reserves, body condition, behavior) of wild fish across biological levels (molecular, cell, organ, individual) And, ii) how the past history of exposure to metal pollution would affect their plastic responses to the experimental contamination? We have predicted that the exposure to combined contamination and immune challenge would influence mostly labile traits such as behavior and physiology through shifts in energy allocation for investment in detoxification process and immune response. We also have predicted that populations of fish would display contrasted sensitivity to stressors. More specifically, fish originating from the most contaminated areas will be better able to cope with the experimental contamination than control unpolluted populations. Keywords : trace metal, immune challenge, sensitivity, stressors interaction

Advancing Chemical Substitution and Alternatives Assessment: Challenges, Opportunities, and Approaches

332

Free-of charge online tools driving substitution

J. Kleimark, A. Lennquist, Chemsec

With the development and global acceptance of the *SIN List* as a chemicals management standard, ChemSec has disclosed the pathway for progressive companies in order to future-proof the business. The SIN List has, since its launch in 2008, become the most important list of chemicals for companies to understand where to focus the efforts in chemicals management. With 15 000 users and the inclusion in many companies RSLs and MRSLs it has formed the basis for substitution work in many areas. In addition to this, the SIN List is an integral part in other sustainability efforts, such as eco labels, and has been endorsed by ECHA as a "driver for innovation". The most important contribution is probably the inclusion in Dow Jones Sustainability Index, where it forms the basis for the most important question in the chemicals sector. Undoubtedly, the SIN List has been a very important contribution in the work towards a reduced use of hazardous chemicals. Consequently, many companies work hard to substitute the hazardous chemicals in products and supply chains with safer alternatives. Until recently, alternatives have hard to find, even though numerous innovative companies develop sustainable solutions, offering products devoid of hazardous chemicals. The alternatives are often not known to a wider audience, due to lack of marketing opportunities and difficulties in bringing sustainable products to market. With our new tool, *ChemSec Marketplace*, we provide a solution to the contradiction between supply and demand for safer alternatives: a global B2B platform dedicated to realize the connection between solution providers and downstream users looking for solutions. Since the launch in the end of 2017, Marketplace has received a lot of attention. Several large chemical producers such as Chemours, Huntsman and Clariant use it to promote their safer alternatives. In addition to this, Marketplace has become the number one spot for innovative SMEs and start-ups to display their alternatives. The number of advertisements (as of Nov 2018) has reached well beyond 100 and the users are above 4 000 per month. The growth, both for users and ads, has been steady during 2018, and we foresee similar numbers for 2019.

333

Integrating life cycle impacts into chemical substitution

P. Fantke, Technical University of Denmark / Quantitative Sustainability Assessment Division; L. Huang, University of Michigan / School of Public Health; M. Overcash, Environmental Genome Initiative / Industrial, Systems, and Manufacturing Engineering Department; E. Griffing, Environmental Genome Initiative; O. Jolliet, University of Michigan / Department of Environmental Health Sciences, School of Public Health

Increasing chemical and product diversity and complexity contribute to exposure of humans and ecosystems to chemicals in millions of product-chemical combinations worldwide. Exposure can occur via product use, or via environmental emissions along entire product life cycles. In response, the European Chemicals Agency outlined a "Strategy to promote substitution to safer chemicals through innovation". Chemical alternatives assessment (CAA) is a suitable tool for chemical substitution, but lacks indicators for impacts along chemical and product life cycles, leaving important tradeoffs unassessed. To address this challenge, exposure and life cycle impacts need to be consistently integrated into CAA. We systematically evaluate the scope of CAA and identify key elements for quantifying exposure and life cycle impacts. We use a tiered approach to assess for different scopes indicators, starting points and assessment outcomes. At each level, cumulative near- and far-field transfers and exposures are linked to chemical mass used in products, emissions, and toxicity information. Other impacts are screened for their contributions to product-related impacts per application type. We test our approach in a case study of plasticizer in vinyl flooring and outline future research needs to operationalizing a Life Cycle-based Alternatives Assessment (LCAA). We demonstrate that it is important to combine factors quantifying chemical mass in product, expsoure and hazard to allow for an overall screening-level ranking of alternatives based on using comparative metrics. Across 10 potential alternatives to DEHP, the non-phthalate plasticizers DEHA and 97A show hazard quotients up to a factor 30 lower. We show that plasticizers contribute between 55 and 85% to total human toxicity burden from flooring. Comparing toxicity with other life cycle impacts emphasizes the relevance of toxicity for the studied chemical-product application. Our results demonstrate how all relevant exposure pathways, populations, and life cycle impacts can be consistently considered to avoid burden shifting resulting from disregarding chemical and product life cycles, and to prioritize the most relevant life cycle impacts. As data and models are becoming more and more available, our appraoch constitutes a valuable starting point for quantitatively and consistently considering exposure and life cycle impacts in CAA. This can ultimately lead to a more comprehesive, yet rapid screening substitution assessment.

334

Environmental impact assessment of substitution of hazardous substances in industry

s. oguzcan, J. Kruopiene, Kaunas University of Technology; J. Dvarioniene, Kaunas University of Technology / Institute of Environmental Engineering
Following the pressure on companies for substitution of hazardous substances as demanded by the EU REACH regulation and other legal frameworks, there was a need for a methodology to assess the impacts of substitution to the environment. Research work was carried out within the project LIFE Fit for REACH, having an aim to encourage substitution of hazardous chemicals in small and medium enterprises (SMEs). The developed environmental impact assessment methodology was tested on a number of companies, including metal and food processing, production of construction materials and household chemicals. The companies involved had problems with carcinogenic, mutagenic, reprotoxic (CMR) substances, endocrine disruptors and volatile organic compounds (VOCs). It was proposed to integrate different levels of indicators, covering the causal chain between pressures (expressed as emissions of targets substances), environmental state (expressed as change in risk characterisation ratio and in environmental impact category indicator values), and response (expressed as amounts of substituted substances). In addition, occupational safety methodology considering the life cycle thinking, as adapted to EU, has been incorporated to cover the life cycle aspects of occupational safety due to accident risks. The methodology has been designed for the environmental impact assessment of substitution of hazardous chemicals. Overall, the indicators were useful in informing the effects of chemical substitution in different areas of impact by covering life cycle stages, major environmental impact categories and workers.The developed methodology can be adopted by various entities with relevant expertise who want to assess the wider environmental impacts of chemical substitution with a more complete set of indicators.

335
The concept of essential use for determining when uses of PFASs can be phased out
I. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry (ACES); G. Goldenman, Milieu; D. Herzke, NILU-Norwegian Institute for Air Research / Environmental Chemistry; A. Lindstrom, U.S. Environmental Protection Agency / NHEERL; R. Lohmann, University of Rhode Island / Graduate School of Oceanography; M. Miller, National Institute of Environmental Health Sciences & U.S. Public Health Service; C.A. Ng, University of Pittsburgh / Civil & Environmental Engineering; S. Patton, Health and Environment Program Commonweal; M. Scheringer, ETH Zurich / Institute of Biogeochemistry and Pollutant Dynamics; X. Trier, European Environment Agency / Green Economy Group, Integrated Environmental Assessments; Z. Wang, ETH Zurich / Institute of Environmental Engineering; J.C. DeWitt, East Carolina University / Pharmacology and Toxicology
Per- and polyfluoroalkyl substances (PFASs) are a group of more than 4700 substances that have been produced since the 1950s and been used in a broad range of consumer products and industrial applications. Based on concerns regarding the high persistence of PFASs and the lack of knowledge on chemical structures, properties, uses, and toxicological profiles of the many PFASs in use, it has been argued in the Madrid Statement that the production and use of PFASs should be limited. It is, however, not practical to ban all uses of all PFASs in one step. If some uses of PFASs are found not to be essential to the functioning of today's society, they could be eliminated without having to first find functional alternatives. Elimination of non-essential uses of PFASs could form a starting point for a process that leads to a global phase-out. In this presentation, I will a) define the concept of essential use and b) apply the concept of essentiality to various use categories of PFASs to determine the feasibility of limiting use. Our approach for defining the concept of essential use is based on the example of the Montreal Protocol, where essential uses are defined. The two elements of an essential use under the Montreal Protocol are that a use is "necessary for health or safety or for the functioning of society" and that "there are no available technically and economically feasible alternatives". In this present work, to identify uses of PFASs that are non-essential, we combine the definition of essential uses with several categories of PFAS uses and ultimately derive 4 distinct use categories, which will be described in the presentation. For uses in categories 1-3, a phase-out of PFASs can be prepared because these uses are not necessary for the betterment of society, i.e., Health Safety, etc. or there are currently functional alternatives available that can be directly substituted into these products or applications. Category 4 are considered necessary and currently have no established alternatives to PFASs. However, this essentiality should not be considered as forever; rather, a constant pressure is needed to search for alternatives. In the presentation, I will provide a detailed description of several ongoing uses of PFASs and discuss whether the uses of PFASs are essential or non-essential based on classification according to the four use categories we have developed. We would like to expand this concept and apply it in detail to all use categories of PFASs.

336
Stochastic High Throughput Stochastic Modeling of Human Exposure to Chemicals in Consumer Products
O. Jolliet, University of Michigan / Department of Environmental Health Sciences, School of Public Health; L. Huang, University of Michigan / School of Public Health; W. Chiu, Texas A M University; K.K. Isaacs, U.S. Environmental Protection Agency / National Exposure Research Laboratory; K. Stylianou, University of Michigan / Environmental Health Sciences; P. Fantke, Technical University of Denmark / Quantitative Sustainability Assessment Division
Recently, increasing attention has been given to human exposure to chemicals in consumer products. Yet, Alternatives Assessment (AA), Risk assessment (RA) and Life Cycle Assessment (LCA) methods lack efficient and flexible approaches to quantify exposure and hazard for the many thousand product-chemical combinations that are currently in use. To address this gap, we present an operational matrix-based high-throughput framework efficiently coupling multi-pathway near-field (worker and consumer) with far-field (general population) exposures and with hazard data vald for thousands of chemcials. The developed assessment framework involving the following steps: a) We use the Stochastic Human Exposure and Dose Simulation Model (SHEDS-HT) to generate the number of users and the mean chemical mass used per user for a simulated US population of 25,000 persons for 9700 chemical-consumer product combinations. b) We calculate as element of a matrix the direct fractions transferred to other compartments and humans, using seven models (skin surface layer, object surface layer, article interior, indoor air, food contact material, pesticide residues, direct emission). Inverting this matrix yields Product Intake Fractions (PiF) for various receptors. c) We then determine the total intake dose per user and per average person in the population for the 9700 chemical-consumer product combinations from SHEDS-HT and d) We predict risks and damage (μDALY) per user and average population. Several of these chemical-product combination yield exposure doses that exceed the reference dose, thus leading to hazard quotient higher than one, the potential impacts on user ranging from less than 0.1 to more than 100 μDALY/pers/d. The average population dose accounting for both users and non-users\n intakes ranges from 8.2E-8 to 3.1 mg/kg_{BW}/d and is dominated by user contributions.The dose received by users and by average population can differ by several orders of magnitude. At population level, two chemicals lead to impacts of 120 to less than 13 μDALY/avg pers/d. These product-chemical combinations correspond to the highest impacts among the 9700 combinations and are those to further study and analyze in priority. Most contributing product usages are associated with personal care products, cleaning products, home maintenance and other home products. The developed approach proves a powerful tool able to analyze thousands of product-chemical combinations.

337
Alternative assessment of hazard chemicals combining in silico tools with multicriteria decision analysis (MCDA): a case study of decabromodiphenyl ether (decaBDE) alternatives
Z. Zheng, Umea University / Department of Chemistry; H. Arp, NGI / Environmental Technology; G.M. Peters, Chalmers University of Technology / Department of Chemistry and Chemical Engineering; P. Andersson, Umea University / Chemistry Department
Alternative assessment is applied for minimising the risk of replacing a hazardous chemical with another problematic, hazardous chemical. High quality experimental hazard data, however, are usually unavailable, especially for newly produced or proposed alternatives. In such cases, obtaining *in silico* data is the only approach to fill in data gaps. An additional concern is how to reach a decision based on uncertain *in silico* data across multiple endpoints. To address these problems, this study explored the use of different multicriteria decision analysis (MCDA) methods within an alternative assessment framework. For this, sixteen alternatives to a widely used flame retardant - decabromodiphenyl ether (decaBDE) - were considered as the case chemicals. This study also discussed what endpoints should be included for assessing the hazard. The hazard endpoints include not only persistence (P), bioaccumulation potential (B) and toxicity (T) which are generally considered by existing alternative frameworks, but also the mobility in water (M) which is fairly recent, and to our knowledge this is the first study to include M within an alternative assessment. Experimental data were collected from free-access databases and *in silico* data were calculated by open-source software or platforms. As expected, the data distribution of experimental data was uneven and large data gaps existed. *In silico* data were calculated for five P criteria, one B criterion, 13 T criteria and one M criterion and were able to address these data concerns. Three MCDA strategies were tested in this case study: heat mapping, MAUT and ELECTRE III. The heat map indicated that none of the target chemical is perfectly sustainable. MAUT and ELECTRE III indicated that the case chemicals include potential regrettable substitutes but also some potential less hazardous alternatives. In aggregate the results of these three MCDA approaches provided meaningful insights in how to use *in silico* data to make an appropriate final-decision strategy for a selection of alternatives.

New Insights into Chemical Exposures over Multiple Spatial and Temporal Scales

338
Spatial variability of ecosystem exposure to home and personal care chemicals in Asia
O. Jolliet, University of Michigan / Department of Environmental Health

Sciences, School of Public Health; J. Hodges, Unilever / Safety and Environmental Assurance Centre; C. Wannaz, Eurisko Research; J. Kilgallon, Unilever / Safety and Environmental Assurance Centre SEAC; L. Speirs, Unilever
There are currently limitations in spatial and temporal resolution of environmental exposure models due to significant variabilities and model uncertainties. Here we present the updated Pangea multi-scale multimedia model based on the more spatially resolved, catchment-based hydrological HydroBASINS dataset covering the entire globe. We apply it to predict spatially-explicit exposure concentrations of two home and personal care chemicals in rivers across Asia: linear alkylbenzene sulphonate (LAS) and triclosan (TCS), and test its potential for identifying/prioritizing catchments with relatively high exposure concentrations. In addition, we also identify the key parameters in the model framework driving predicted high concentrations and perform Monte Carlo uncertainty analyses on emissions and other non-spatial model inputs. The updated combination of Pangea with the HydroBASINS hydrological data represents a substantial improvement for modelling substance fate, with higher resolution and improved coverage in regions with lower flows, with good agreement with monitored concentrations for TCS in freshwater (r=0.74) and sediment (r=0.9). The ranking of water basins by predicted PECs showed highest concentrations (Indus, Huang He, Cauvery, Huai He and Ganges), one to two orders of magnitude greater than the water basins with lowest predicted PECs (Mekong and Brahmaputra). Emissions per unit volume of each catchment, chemical persistence, and river discharge were deemed to be the most influential factors on the variation of predicted PECs. For rapidly degraded LAS, only a few upstream catchments situated in proximity contribute substantially to the predicted PECs, whereas a much larger number of upstream catchments over 2000 km contribute to the predicted PECs for more persistent TCS. Focusing on the Huang He (Yellow River) water basin, uncertainty confidence intervals are much lower than the variability of PECs across the Huang He catchments.

339
The first global study of pharmaceutical contamination in riverine environments
J. Wilkinson, The University of York / Natural and Built Environments; A. Boxall, University of York / Environment and Geography Department
Significant knowledge gaps exist regarding the occurrence of APIs in the environment, particularly in low to middle-income countries and those outside of N. America and W. Europe. Of the 196 countries recognised by the United Nations, data for the occurrence of pharmaceuticals is only available for 71. Here we present the first global pharmaceutical monitoring study in order to identify hot-spots of pharmaceutical contamination in rivers worldwide. Involving a consortium of 62 collaborators, the study composed of 71 sampling campaigns performed across 61 countries covering all continents (n=537). Thermally-insulated water sampling kits were sent to partner intuitions who then collected 10mL of water from 5-10 locations along their study river(s). All samples were filtered in-field using a glass microfiber syringe filter (0.7μm pore size). Samples were sent frozen and on ice to the University of York (York, UK) for quantification of 61 APIs using an in-house validated direct-inject HPLC-MS/MS method. At least one API was detected in all of the countries analysed and as many as 33 were detected in a single catchment (Lahore, Pakistan). Highest sum concentrations were found in rivers suspected to receive discharge from pharmaceutical manufacturing facilities in Lahore in Pakistan, Delhi in India and Lagos in Nigeria (Figure. 2). The most frequently detected API in Africa was the antibiotic ciprofloxacin with a detection frequency (DF) of 55%, in Asia the anti-hyperglycaemia drug metformin was most frequently detected (DF=79%). For the other continents, carbamazepine (DF=78%), gabapentin (DF=77%), paracetamol (DF=54%) and ciprofloxacin and fluconazole (DF=67% each) were the most frequently detected APIs in Europe, Oceania, N. America and S. America respectively. Initial analyses indicate that per capita gross domestic product on a purchase power parity-basis may reflect API contamination where low 'middle-income' countries show highest sum API concentrations. This may be reflective of the fact that while these countries have ready access to medicine, the level of investment in and regulation of wastewater treatment remains low. To the best of our knowledge, this is the first study exploring API contamination of rivers on a global-scale. Our results clearly show that the occurrence of pharmaceuticals in rivers is an issue that affects the whole planet and much work is needed to identify potential impacts in poorly-studied regions.

Pharmaceutical translocation from wastewater into bee hives
L. Carter, University of Leeds / School of Geography; A. Agatz, IBACON GmbH / Ecological Modelling; A. Kumar, CSIRO / Center for Environmental Contaminants Research; M. Williams, CSIRO / Land and Water
The potential for pharmaceuticals to accumulate in pollen and nectar has been a topic that has been very much over looked with research predominantly focussing the accumulation of these chemicals in shoots and roots. Nevertheless, a similar chemical profile and known ability to cross the root membrane and translocate within a plant would suggest that like insecticides, pharmaceuticals, have the potential to accumulate in nectar and pollen. There is therefore an urgent need to establish the potential for these biologically active chemicals to accumulate in nectar and pollen and to understand the subsequent exposure to bees and the beehive. Residues of carbamazepine were detected in nectar (1.75 – 371.41 ng/mL) and pollen (0.02 – 30.85 μg/g) sampled from zucchini flowers (*Curcubita pepo*) exposed to carbamazepine spiked soil (0.5 – 20 mg/kg). It was estimated that the concentration of carbamazepine in nectar and pollen would be 70 fg/mL and 880 fg/g respectively, under a realistic soil exposure of carbamazepine (20ng/kg) based on a linear relationship between carbamazepine concentrations in soil and nectar/pollen (R^2 >0.99). Incorporation of these estimated carbamazepine residues into the BEEHAVE modelling framework enabled the simulation of the potential transfer of carbamazepine to 11 beehives at a landscape scale over three simulated years (2010, 2011, 2015). The amount of carbamazepine gathered increased exponentially during the flowering period of zucchini reaching a maximum carbamazepine concentration in a single hive of 86.97 ng. Annual average concentrations ranged between 8.73 and 30.65 ng across the 11 hives in the 5km landscape. Carbamazepine accumulation varied between hives within the same year by up to two orders of magnitude. These findings demonstrate the importance of the hive location, weather, and time on carbamazepine accumulation. Carbamazepine residues in the pollen contributed to on average 5-6 times more carbamazepine in each colony than nectar on an annual basis. This work describes a fundamental first step in the quantification of pharmaceuticals in nectar and pollen and demonstrates that more work is urgently needed on this topic. A detailed understanding of the potential transfer of pharmaceutical residues to the beehive will enable scientists and regulators to be able to design experiments to consider the risk of this exposure (e.g. larval toxicity) by considering realistic exposure doses of pharmaceuticals.

341
Understanding Insect-Mediated Contaminant Flux: When, Where, and How to Look for Contaminant Export by Emergent Aquatic Insects
R.R. Otter, G. Beaubien, C. Olson, Middle Tennessee State University / Biology; D. Walters, USGS / Columbia Environmental Research Center; M. Mills, U.S. EPA / National Risk Management Research Laboratory
The exchange of subsidies across the land-water interface is a key driver of community dynamics and ecosystem processes in both aquatic and riparian habitats as organic matter, nutrients, and animals flow between these systems. However, biological vectors can also transport contaminants across the land-water boundary. A classic example of contaminant-linked subsides came from early studies of egg shell thinning in birds. In these studies, reproductive failure in piscivorous birds (e.g., eagles and pelicans) was linked to DDT exposure from consumption of fish that had accumulated in the aquatic ecosystem. Like birds, adult aquatic insects have been shown to transport significant quantities of contaminants such as PCBs out of aquatic environments, thereby linking aquatic contamination to terrestrial predators via a phenomenon called insect-mediated contaminant flux. Here, we present: 1) a conceptual model for insect-mediated contaminant flux based on four critical ecological processes that govern export of contaminants. 2) A decision-making tool to assess the likelihood of terrestrial risk via insect-mediated flux. This tool, named the Riparian Impact Test, integrates the technical science of the conceptual model into a step-wise series of four questions to aid risk assessors. 3) Practical considerations for risk assessors, including how to best sample for insect-mediated contaminant flux at a specific site.

Towards a temporally and spatially resolved Nested Exposure Model for organic contaminants in Arctic marine ecosystems
I.S. Krogseth, Norwegian Institute for Air Research / Environmental Chemistry; K. Breivik, NILU - Norwegian Institute for Air Research; F. Wania, University of Toronto, Scarborough / Physical and Environmental Sciences
There is concern over possible effects on Arctic ecosystems from exposure to persistent organic pollutants (POPs) and chemicals with similar properties. To enable scientifically sound response strategies, a mechanistic understanding of the complete link between chemical emissions and resultant concentrations in ecosystems is fundamental. The main objective of this study is to develop, evaluate, and apply a new Nested Exposure Model (NEM) consisting of (i) a global spatially and temporally resolved module for fate in the physical environment and (ii) a bioaccumulation module, currently developed for European Arctic marine ecosystems. Here, evaluation of the bioaccumulation module across trophic levels and time is presented. The dynamic model ACC-HUMAN Arctic was adapted to represent ecosystems in the Svalbard and Barents Sea areas. The model includes herbivorous, omnivorous, and carnivorous zooplankton, fish (herring, capelin, polar cod, and Atlantic cod), and ringed seal. Model performance was evaluated for selected polychlorinated biphenyls (PCBs) in Kongsfjorden (79 °N 11 °E) and in the wider Barents Sea. As suitable long-term empirical time trends for PCB concentrations in the physical environment remain fragmented, different scenarios were constructed to evaluate the model. The best model performance was achieved when running the model using as input the time-trends of PCBs in seawater predicted for the Baltic Sea region, but adjusted to concentrations observed in Arctic seawater. Using this scenario, the bioaccumulation module performed well in reproducing bioaccumulation of PCBs in the Kongsfjorden food web. The ratio of predicted to measured concentrations ranged from 0.3 – 6.7 except for PCB 28 in ringed seal (ratio of 16-19). Predicted

time-trends of ΣPCB_6 and ΣPCB_7 were also in good agreement with measurements from the Barents Sea for all fish species. The good model performance across trophic levels and time is promising for further expansion of the model to include (i) variation in space through connection with the physical module of NEM, and (ii) Arctic marine top-predators, the terrestrial environment, and human exposure. The physical module of NEM is still under development, but preliminary results will be presented. When finalized, we hope that the NEM model will be a useful tool for scientific and regulatory communities interested in understanding and protecting ecosystem and human health from legacy and emerging organic contaminants.

343
What can we learn from the temporal trend of human exposure and concentrations of PBDEs?
L. Li, University of Toronto, Scarborough / Department of Environmental Sciences; C. Hoang, University of Toronto at Scarborough / Department of Physical and Environmental Sciences; J.A. Arnot, ARC Arnot Research & Consulting / Adjunct Professor, Department of Physical & Environmental Science/Department of Pharmacology and Toxicology; F. Wania, University of Toronto at Scarborough / Department of Physical and Environmental Sciences
A number biomonitoring programs have observed declining trends in concentrations of polybrominated diphenyl ethers (PBDEs) in human tissues in response to national regulation or restrictions; however, the rate of decline often varies between congeners, ages, and countries. In this presentation, we systematically investigate the mechanisms responsible for such variability through modeling time-variant lifetime exposure to four PBDE congeners (47, 99, 153, and 209) via multiple exposure pathways (e.g., “far-field” food consumption and “near-field” non-dietary object-hand-mouth contact) from multiple lifecycle stages (industrial processes, the indoor and outdoor use phases, and waste disposal) in interconnected indoor, urban and rural environments. Our model simulation indicates that, after the ban of new PBDE uses, concentrations of congeners with (i) a dominant exposure contribution from far-field exposure routes and (ii) higher resistance to biotransformation in the human body, tend to decline slower. Because of continued release of PBDEs from disposed waste after the end of the lifespan of consumer articles, contamination in far-field environmental media (e.g., rural air and freshwater) and organisms (i.e., the source of foodstuffs) outlasts that in near-field environmental media (e.g., indoor air and surfaces). We, therefore, can expect a chemical with dominant exposure through far-field routes to exhibit a slower rate of decline. This can be the case for (i) more persistent and less volatile congeners (e.g., BDE-153, which is more bioaccumulative and with lighter emissions at the indoor use phase than other congeners), (ii) exposure of adults (due to higher food consumption rate and less frequent object-hand-mouth contact), and (iii) regions with considerable far-field end-of-life emissions. The presentation illustrates how exposures over multiple spatial and temporal scales interact to determine the dynamics of the human body burden of PBDEs.

Revision of the EFSA Guidance Document on Birds and Mammals

344
Revision of the EFSA guidance document on 'Risk Assessment for Birds and Mammals'
R. Sharp, D. Auteri, EFSA - European Food Safety Authority / Pesticides Unit; M. Arena, EFSA - European Food Safety Authority / Pesticides; G. Fait, EFSA European Food Safety Authority / Pesticides Unit
In order to gain EU Level approval of an active substance under Regulation (EC) 1107/2009, it is necessary to demonstrate that there are no unacceptable risks to bird and wild mammals. After nearly ten years since the publication of the EFSA guidance document titled ‘Risk Assessment for Birds and Mammals’. (EFSA, 2009). EFSA has received a mandate to update it. The main aim is to revise the guidance with the latest scientific knowledge and to provide further clarifications on aspects of the guidance which were commonly misinterpreted. A fundamental step in the revision is the consultation of stakeholders to ensure that the revised guidance is fit for purpose. To this end, EFSA launched a public consultation of the EFSA (2009) guidance document in 2017. Another public consultation is planned on the draft revised guidance. A summary will be given of the plan for the revision of the guidance document and the key issues identified by the public consultation which require consideration during the development of the revised guidance.

345
Revision of the EFSA Guidance Document on Birds and Mammals: Industry view
M. Foudoulakis, Corteva Agriscience, The Agriculture Division of DowDuPont / CPRS; J. Pascual, BASF SE / Ecotoxicology; M. Ebeling, Bayer AG Crop Science Division / Ecotoxicology - Terrestrial Vertebrates Expert Team; J. Hahne, Bayer AG Crop Science Division; T.B. Fredricks, Bayer CropScience / Global Regulatory Sciences; P. Manson, Cheminova A/S European Regulatory Office / Global Regulatory Science; R. Murfitt, Syngenta Ltd / Environmental Safety
The EFSA Guidance Document on the Risk Assessment for Birds and Mammals [EFSA, 2009)] (EFSA GD) has been used for more than 8 years in the EU for the evaluation of active substances and Plant Protections Products. This GD is now under formal revision by EFSA. SETAC Europe 2019 is an appropriate forum to share among risk assessors and other stakeholders the experiences with the use of the current GD and provide recommendations and proposals for its ongoing revision. Industry will contribute by sharing the experience from risk assessors who have been using this guidance on daily basis, highlighting those areas where the revision should put more emphasis. Our experience is mainly based on the scientific assessments conducted by risk assessors from regulatory bodies in the EU (Member States and EFSA) as presented in regulatory documents for the registration of active substances and PPPs. The basic principles of the risk assessment in the current GD (conservative tier 1 calculations for the in-crop acute and reproductive risks and options for higher tier refinement) have in general worked adequately and should be maintained. The major issues have occurred with the refined risk assessments, particularly for the reproductive (long-term or chronic) risk. The ongoing revision of this GD should take into consideration the weaknesses observed during its implementation by risk assessors during the last years: different interpretation and use of refinement options by different risk assessors from authorities with the same data. To address these issues, the revised GD should provide a more detailed technical description and guidance on some refinement parameters and better define which options for refined risk assessment could be widely used and accepted by risk assessors. The main refinement parameters that, in the opinion of risk assessors from industry, require particular attention for the revision are: selection of focal species of birds and mammals, relevance of the vole scenario, ecotoxicologically relevant reproductive endpoint for mammals, residues in food items, proportion of food (PT) taken in treated areas, field effects studies and modelling.

346
Collection of ecological data and residue data in food items to be used in pesticide risk assessment for birds and mammals
J. Lahr, Wageningen Environmental Research / Team Animal Ecology; W. Krämer, AGES / Austrian Agency for Health and Food Safety; V. Mazerolles, ANSES / Agency for Food, Environmental and Occupational Health & Safety; V. Poulsen, ANSES; D. Jölli, Austrian Agency for Health & Food Safety / Institute of Plant Protection Products; M. Müller, AGES; E. McVey, J. Wassenberg, Ctgb; R. Derkx, A. Brouwer, Wageningen University & Research / WUR Library; J. Deneer, Wageningen Environmental Research / ERA team; W. Beltman, Wageningen Environmental Research / Environmental Risk Assessment; D. Lammertsma, H. Jansman, R. Buij, Wageningen Environmental Research / Team Animal Ecology; M. Arena, R. Sharp, D. Auteri, EFSA - European Food Safety Authority / Pesticides Unit
The current EFSA Guidance Document (GD) for the risk assessment of plant protection products for birds and mammals (EFSA, 2009) follows a tiered approach. The GD provides options for higher tier risk assessment, in cases where a low risk cannot be identified with the first tier risk assessment. The refinement steps may include: (1) the identification of specific focal species (FS), (2) the use of measured residues and measured residue decline in FS food items, (3) field information on the composition of diet obtained from an area treated with pesticide (PD factor), and (4) field information on the proportion of an animal’s daily diet obtained in a real habitat treated with pesticide (PT factor). In order to enable proper and consistent use of such data, EFSA initiated a project that was conducted from 2016 to 2018. The screening of data submitted for approval/authorization of pesticides yielded close to 1,000 relevant regulatory papers (i.e., mostly confidential reports by companies) and about 600 relevant public papers cited in the Draft Assessment Reports (DAR’s) or Renewal Assessment Reports (RAR’s). The searches in the public literature bibliographies yielded almost 30,000 ‘hits’ but only 1-2% of these papers were relevant enough to be screened and summarised. The final MS-Excel databases with relevant data for birds, mammals and residues contain 3196, 1439 and 2937 records respectively. The residue database contains entries on 190 active substances and metabolites. Fungicides, herbicides and insecticides represent 99% of all records. For crops, the highest number of records in the databases stem from residue studies on cereals, vegetables, maize, in orchards and vineyards, and for birds and mammals, from grassland studies. The ecological databases contain data on about 150 bird species and 70 mammal species. The food items represented in the ecological databases included all major food item categories, but especially crop seeds and plants, both monocotyls and dicotyls. This may be due to the fact that many studies were conducted for granivorous and herbivorous animals. The focus of the records in the residue database was on monocotyls and dicotyls and on fruits, with only few records on arthropods and very few on weed/crop seeds and worms. The data collection could serve as a valuable basis for future developments in the risk assessment for birds and mammals.

Industry data for the revision of the EFSA GD on Birds and Mammals
J. Hahne, Bayer AG CropScience Division; M. Ebeling, Bayer AG Crop Science Division / Ecotoxicology - Terrestrial Vertebrates Expert Team; M. Foudoulakis, Corteva Agriscience, The Agriculture Division of DowDuPont / CPRS; R.

Murfitt, Syngenta Ltd / Environmental Safety; J. Pascual, BASF SE / Ecotoxicology

The EU risk assessment guidance for birds and wild mammals (EFSA 2009) will be revised, and therefore the present guidance should be checked whether the current parameters and recommendations should be updated. For this revision, industry is providing data via two different processes. First, individual companies have provided more than 800 study reports to the EFSA tender for data compilation. Second, the ECPA companies are jointly compiling, analysing data and making publications; data, calculations tools and reports are offered to EFSA for the revision of the GD. Four of these projects are presented here: 1) Residue dissipation (DT50): The EFSA GD assumes a "generic" DT50 of 10 days for dissipation of residues from food items (eg foliage). The underlying residue data were largely from older studies with unclear relevance for modern agriculture in Europe. We evaluated more modern and relevant foliage residue decline studies and found that the generic DT50 of 10 days is indeed a conservative assumption. No significant differences were found for the DT50 in monocot or dicot foliage, or between the Northern or Southern EU residue zones. 2) Residue estimation for fruits: The current EFSA GD provides RUDs for residue estimation on bird and mammal food items, including fruits of different types. The ECPA team has evaluated residue studies with fruits like grapes, 'other berries', gourds, and large fruits from orchards. The large dataset (n≥100 trials per food item) revealed significantly lower mean RUDs compared to the current default values, particularly for gourds and large fruit from orchards. 3) LD50 extrapolation for mammals: The current EFSA GD provides extrapolation factors for the acute oral toxicity tests in birds to determine a point estimate for the LD50 for studies in which no or little toxicity was observed. The ECPA expert team has now established such extrapolation factors also for mammals. 4) 21-d PT for long-term risk assessment: The "PT-factor" in the current EFSA GD represents the portion of time an animal spends potentially foraging in a treated field. Individuals tracked over more than a single day often show significant variation from one day to another. Therefore the ECPA team has developed an evaluation method that accounts for both the inter-individual and the intra-individual variation. Here we present follow-up work including also other species of potential concern (eg, skylarks or hare).

348

From focal species to effects studies: important points for the revision of the EFSA Guidance Document on B&M

R. Dittrich, Tier3 Solutions GmbH / Wildlife Ecology; M.M. Benito, Tier3 Solutions GmbH; I. Hotopp, Tier3 Solutions GmbH / Regulatory Science; B. Giessing, Tier3 Solutions GmbH; O. Fuelling, Tier3 Solutions GmbH / Field study; C. Wolf, Tier3 Solutions GmbH

The planned update of the Guidance Document (GD) on the risk assessment (RA) for birds and mammals for plant protection products (PPPs) is a great opportunity to clarify topics which are not specified in detail in the current version. For example, field effects studies are one acknowledged option to verify acceptable risk, but no detailed information is given about their required test design. Therefore their acceptance by member states varies due to doubts regarding the study validity. However, field effects studies can measure potential effects of PPPs under realistic field conditions and reduce the use of over-conservative assumptions, so they are a valuable tool to cover uncertainties. Major critical points of a field effects study are the selection of the focal species and the adequate study design and sample size. The focal species should represent the worst-case in terms of exposure and by doing so, it becomes protective of other species. However, this concept is not always applied by the regulatory authorities, which shows the need to strengthen the standards given in the GD. On the other hand, the study design needs to be defined according to specific concerns in each case. The minimum number of necessary individuals or sites can be estimated by means of statistical simulations, based on industry data or literature information. This is an important factor, as having the right sample size allows to cope with the high variability of natural conditions. **Acute effects on birds or mammals** can be studied by using the technique of radio tracking. Any lethal but also sublethal effects are detected by regular checks of individual activity. **Reproductive effects on small mammals** can be tested using capture-mark-recapture technique and either an intensive approach or a landscape approach (different in the number of sites and in the trapping scheme) depending on the focal species and the target crop. **Reproductive effects on wild birds** can be tested by nest monitoring studies. The reproductive performance following a PPP application can be shown using the same endpoints as in tier1 avian reproduction tests and for further key parameters like nest survival and number of fledglings per pair. Field effects studies provide an accurate assessment of the impacts of PPPs in the nature. They add realism in the otherwise theoretical risk assessment and therefore further guidance should be given in the context of the revision of the EFSA GD on birds and mammals.

349

How to use radio tracking data from multiple tracking sessions in refining the risk to birds and mammals from the use of pesticides

M. Fryer, Chemicals Regulation Division, Health and Safety Executive / Ecotoxicology; P. Hamey, HSE Health and Safety Executive; M. Reed, HSE; C. Taylor, HSE Health and Safety Executive; M. Clook, HSE Health and Safety Executive / Chemicals Regulation Directorate

One of the refinements used in the bird and mammal risk assessment for plant protection products is to consider the amount of food that an individual obtains from a treated field. This is usually referred to as PT or the proportion of an animal's daily diet that is obtained in habitat treated with pesticide. It is usual for this refinement to be based on radio-tracking of individuals of a species of concern or relevance. The radio-tracking data indicate a "day in the life" of an individual, however the data are often used to refine the long-term/reproductive risk assessment, hence there is a potential mismatch between the time period used in the refinement and the risk assessment. This presentation will describe how radio-tracking data have typically been used by regulatory authorities in bird and mammal risk assessment. Recently Ludwigs *et al.* (2017) have published work regarding how to produce a 21-day time averaged value for PT using a Monte Carlo method, which may be relevant for the long-term/reproductive risk assessment. This method uses data from multiple tracking sessions for individual birds/mammals. The European Food Safety Authority; Guidance Document on Risk Assessment for Birds & Mammals (2009) does not specify how to use radio-tracking data from multiple sessions for the same individual, which can lead to inconsistencies in interpretation. The UK Health and Safety Executive (HSE) has therefore reviewed the method described by Ludwigs *et al.* in a position paper. While this method raises important issues and illustrates how more use can be made of PT datasets, there are several concerns regarding how the method has been implemented. This presentation will discuss the method proposed by Ludwigs *et al.* and the concerns identified with this approach by UK HSE. These concerns have been broadly grouped into toxicological, ecological and statistical points. The Ludwigs *et al.* paper represents an important development in the use of radio telemetry data but does not detail a universal method that can be applied to any PT dataset. The points raised in this presentation should be further considered when designing a radio-tracking study or when using the data from such a study in risk assessment.

Epigenetic and Evolutionary Effects of Environmental Stressors on Environmental and Human Health

350

Genomic signatures of heavy metal tolerance in the soil arthropod Orchesella cincta

D. Roelofs, A. Harajizadeh, Vrije Universiteit / Department of Ecological Science; Z. De Corte, Royal Belgian Institute of Natural Science; B. Van Hest, Vrije Universiteit / Department of Ecological Science; J. Mariën, Vrije Universiteit Amsterdam / Department of Ecological Science; F. Hendrickx, Royal Belgian Institute of Natural Science

A major component of urbanization encompasses the accumulation of toxicant substances. Heavy metals have received considerable attention as they are known to accumulate at ever increasing rates in the environment. Exposure to these toxicants constitute novel environments and the degree to which organisms may evolve genetic tolerance towards these stressors remains poorly understood. Exposed populations of the soil arthropod *Orchesella cincta* evolved metal tolerance through increased metal excretion efficiency and, consequently, a decreased cadmium (Cd) growth reduction. Previous research further demonstrated that the observed tolerance of adapted populations largely involves constitutive over expression of genes involved in metal detoxification. Yet, the degree to which this tolerance is reflected at the genomic level remains at present unknown. Therefore, we present the analysis of genome wide allele frequency data from three adapted and four reference populations, obtained by Restriction-site Associated DNA sequencing (RADseq), to test for genetic signatures of selection. Mapping SNP loci that confer signatures of genetic adaptation to the fully annotated genome of this species allows association between the genomic targets of selection and the genes that show altered constitutive and induced expression in response to metal exposure. Interestingly, several of these genes were already identified in a previous transcriptome analysis to be among altered gene transcripts in metal tolerant phenotypes. These results do not only inform us about the capacity of natural populations to genetically adapt to human stressors, but also how integration of different approaches (phenotypic/outlier locus detection/transcriptomics) may reveal signatures of adaptation.

351

Multigenerational exposure to CuO NMs with Enchytraeus crypticus - nanomaterials and epigenetics?

R. Bicho, Universidade de Aveiro / CESAM Department of Biology; J.J. Scott-Fordsmand, Aarhus University / Biosciences; M. Amorim, Universidade de Aveiro / Department of Biology and CESAM

Chemical stressors can induce epigenetic changes, i.e., genomic changes that are transferred to the next generation, even when the stressor is removed: transgenerational. This is well-known for humans and carries additional concern, but has been especially less studied in environmental relevant species. In this study we assessed the epigenetic potential of Cu materials in terms of global and specific methylation, combined with gene expression allowing to target genes involved in among others DNA methylation, histone modifications and non-coding RNA. We exposed the standard soil model species *Enchytraeus crypticus* in a multigenerational (MG) test to Cu (copper oxide nanomaterials (CuO NMs) and copper salt ($CuCl_2$)). Sub-lethal effect concentrations (start generatoion) were used for 4 consecutive generations (plus 2 generations transferred to clean media, F1 to F7 generations in total). The results showed that MG exposure of Cu caused an increased in the average global DNA methylation but significance not shown. Gene expression showed changes in the epigenetic, stress and detoxification gene targets, depending on the generation and Cu form, also occurring in post-exposure generations - transgenerational. Differences observed between Cu forms indicate nanoparticulate specific effects. Again, highllighting the importance of long-term studies for risk assessment.

352

Exposure to copper during embryogenesis caused a transient increase in tolerance in the three-spined stickleback (Gasterosteus aculeatus) for two subsequent generations

H. Littler, University of Exeter / Biosciences College of Life and Environmental Sciences; L.V. Laing, University of Exeter / Biological Sciences; J.A. Fitzgerald, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology; N. Bury, University of Suffolk / School of Science, Technology and Engineering; T. Uren Webster, Swansea University / Department of Biosciences; R.J. Wilson, University of Exeter / Biosciences; R. van Aerle, Centre for Environment Fisheries and Aquaculture Science / Biosciences College of Life and Environmental Sciences; J. Mill, University of Exeter / Exeter Medical School; E.M. Santos, University of Exeter / Biosciences College of Life and Environmental Sciences

Exposure of wildlife to environmental pollutants can occur continuously or intermittently over long periods of time, and their surivival is dependent on their ability to adapt to these exposures. We conducted a series of copper exposures in stickleback (*Gasterosteus aculeatus*) to investigate whether prior exposure can result in altered susceptibility later in life and/or in subsequent generations. A copper pre-exposed population was generated by exposing stickleback embryos to low-level copper during early life (0-9 days post-fertilisation), causing ~1.2% mortality, ensuring that selection for a tolerant genotype did not occur. These F0 fish were then kept under control conditions until maturity (9 months) and bred to produce F1 and F2 adults with no further exposure. A control population was generated in parallel. To assess altered susceptibility within a generation, F0 adults from the pre-exposed and control populations were re-exposed to copper. Prior to re-exposure, basal tissue copper content was significantly higher in pre-exposed fish compared to controls. In addition, pre-exposure affected copper content upon re-exposure, suggesting that embryonic exposure altered copper metabolism later in life. We hypothesise that this change is due to an altered physiological response, potentially caused by stable epigenetic alterations induced during early life exposure. This is currently being investigated using RNA-seq and whole genome bisulfite sequencing. To assess altered susceptibility of future generations, we exposed embryos from both the pre-exposed and control populations to copper during early life. F1 embryos from pre-exposed parents were significantly more tolerant to copper compared to controls. This tolerance was maintained in the F2 generation, but not the F3 generation. We hypothesise that the multigenerational tolerance observed up to the F2 generation was caused by parental effects, owing to altered copper handling and increased copper tissue burden in F0 adults, resulting in secondary exposure of F1 embryos and their germ cells which gave rise to the F2 generation. Our data support the hypothesis that exposure to low levels of copper during early life has the potential to reduce the susceptibility of vertebrates to subsequent exposure across generations, potentially via a combination of epigenetic, physiological, and maternal effects.

353

Bioaccumulation and morphological traits in a multi-generation test with two Daphnia species exposed to Lead

G. Araujo, University of Aveiro / Department of Biology and CESAM; M.D. Pavlaki, University of Aveiro / Department of Biology; A. Soares, University of Aveiro / Department of Biology and CESAM; D.M. Abessa, UNESP Universidade Estadual Paulista Júlio de Mesquita Filho / Department of Biosciences; S. Loureiro, Universidade de Aveiro / Biology

Anthropogenic pressures negatively affect the environment in different ways and at different levels. Lead (Pb) is a non-essential toxic metal being often detected in aquatic ecosystems. Xenobiotics like Pb can induce deleterious effects in different ways to different species, include close phylogenetically related species. In this study, two daphnid species, the temperate *Daphnia magna* and the tropical *Daphnia similis,* were used to assess a long-term Pb exposure, within a nine generations exposure to 50 μg/L. Besides Pb body burdens, effects were evaluated looking at non-commonly used endpoints like granules in the dorsal region of neonates, reddish extremities, carapace deformation and morphology, production of males and ephippia (or dormant haploid egg), changes in the eggs' color and abortion. The test was conducted under a usual and restricted food regime ($3x10^5$ and $1.5x10^5$ cells/mL). After 5 exposure generations, neonates were changed to a clean media for three other generations (F6 to F9) to assess recuperation. Negative and adverse effects occurred, but no disparity between species was shown. The *D. magna* Pb accumulation showed different patterns regarding food regime, being faster under usual food, and reaching a saturation point, whereas a gradual increase occurred under food restriction. A full retrieval occurred regarding Pb in *D. magna*, since no difference between control and recovering organisms was evidenced (Pb body burdens). Long-term Pb exposure led to carapace malformations, Pb aggregation in neonates' dorsal region, reddish extremities, production of males, ephippia (or dormant haploid egg), aborted eggs, and changes in eggs' color (green and white). Food restriction also induced the production of males. Reddish extremities disappeared in recovering organisms and ephippia (or dormant haploid egg) did not occurred during the recovery period. Bioaccumulation of Pb and adverse effects occurred at 50μg/L, although safety threshold reported for instance in the Brazilian legislation are within this Pb level, and scientific literature report occurring above 400 mg/L of Pb.

354

Intra-generational effects of early life-stage exposure to tebuconazole on reproductive capacity of Zebrafish (Danio rerio)

C. Miller, University of Lethbridge / Biological Sciences; Y. Ilnytskyy, I. Kovalchuk, University of Lethbridge; S. Wiseman, University of Lethbridge / Biology

Tebuconazole (TEB) is fungicide used globally in agriculture to control for pathogenic species common to a variety of fruits, vegetables and cereals. It elicits endocrine disrupting effects through inhibition of the activity of cytochrome P450 enzyme, aromatase, which converts testosterone into 17β-estradiol (E2). Research suggests that exposure to endocrine disrupting compounds during early stages of development can impair reproductive physiology of adults. One mechanism of this effect is alterations to the DNA methylome that result in permanent reprogramming of gene expression. The goal of this study was to determine whether exposure to TEB during early stages of development affects the reproductive capacity of sexually mature adult Zebrafish (*Danio rerio*), and to investigate the mechanistic basis of any effects. Embryos were exposed to either a control (0 μg/L), 10 μg/L, or 1000 μg/L of TEB from 1-hour post-fertilization until 24-hours post-hatch. Larvae were then transferred to uncontaminated water and reared until sexual maturity. In embryos and adults, there were no significant effects of either concentration of TEB on mRNA abundance of genes along the HPGL axis or E2 concentration in plasma of adult fish. The mRNA abundance of ten-eleven translocase (*tet*) *3* was significantly greater in embryos exposed to 10 μg/L, and mRNA abundance of DNA methyltransferase (*dnmt*) *3b1*, *tet1*, *tet 2*, and *tet 3* were significantly greater in embryos exposed to 1000 μg/L. In adults, mRNA abundance of *tet 1* was significantly reduced in gonads from males exposed as embryos to 1000 μg/L. In brain of adults exposed as embryos to 10 ug/L, there was a significant decrease in mRNA abundance of *dnmt 2* and *dnmt 3b4* inmales and a significant increase in mRNA abundance of *dnmt 3a2* and *dnmt 3b1* in females. In brain of adults exposed as embryos to 10000 ug/L, there was a significant decrease in *dnmt 2, dnmt 3b4, tet 1*, and *tet 2* in males, and asignificant decrease in mRNA abundance of *dnmt 3a1, dnmt 3b2, dnmt 3b4, tet 1*, and *tet 2* in females. Using reduced-representation bisulfite sequencing (RRBS), 16 differentially methylated regions (12 hypomethylated and 4 hypermethylated) of the genome were identified in gonads of adult females exposed as embryos to 10 ug/L of TEB. Overall, results of this study suggest that the DNA methylome is a target of TEB during early stages of development but effects on DNA methylation do not appear to cause impaired reproductive capactity.

355

DNA- and RNA-methylation in Baltic amphipods by using liquid chromatography coupled to high resolution mass spectrometry

H.V. Motwani, Stockholm University / Department of Environmental Science and Analytical Chemistry (ACES); G. Martella, Stockholm University, ACES / Department of Environmental Science and Analytical Chemistry; E. Gorokhova, Stockholm University / Department of Environmental Science and Analytical Chemistry (ACES); N. Motwani, Stockholm University; B. Sundelin, Stockholm University / Department of Environmental Science and Analytical Chemistry (ACES)

Adductomics can be defined as the screening of all additions (adducts) on a biomacromolecule. We have developed a liquid chromatograph-high resolution mass spectrometry (LC-HRMS) method for DNA- and RNA-adductomics using an Orbitrap Q Exactive HF mass spectrometer equipped with a heated electrospray ionization source. In this method we screened for adducts by taking advantage of the common deoxyribose (116.0473 Da) or ribose (132.0423 Da) moiety present in DNA- or RNA-nucleosides, respectively, after enzymatic hydrolysis of the biomacromolecules and chromatographic separation. The developed method was able to resolve DNA- and RNA- epigenetic markers, namely 5-methyl-2'-deoxycytidine (5-me-dC), N^6-methyl-2'-deoxyadenosine (N^6-me-dA), 5-methylcytidine (5-me-C) and N^6-methyladenosine (N^6-me-A), with high mass accuracy (< 3ppm). Subsequently, the developed method was applied to amphipods *Monoporeia affinis* collected within the Swedish National Marine Monitoring program having aberration frequency ≤5%. Twenty one females with the embryo brood removed and their broods were analyzed separately for DNA methylations (5-me-dC and N^6-me-dA) and RNA methylations (5-me-C and N^6-me-A). The extraction method employed with Chelex resin allowed for obtaining

sufficient amount of DNA and RNA from the same female or brood. Mean percentage (± standard deviation) of methylation corresponding to the unmethylated nucleoside [in the form of 5-me-dC×100/(dC+5-me-dC)] was approximately 11 (±3)% 5-me-dC, 0.023 (±0.013)% N^6-me-dA, 1.3 (±0.2)% 5-me-C and 0.94 (±0.17)% N^6-me-A in the females, and 6.7 (±2.2%)% 5-me-dC, N^6-me-dA below quantification limit, 17 (±12)% 5-me-C and 1.8 (±1.2)% N^6-me-A in the embryo broods. The relatively high standard deviation in the embryo broods is attributed to differences in their developmental stage and possible matrix effects. Nevertheless, the results can be used to compare the ratio of 5-me-dC to 5-me-C and 5-me-dA to 5-me-A in the females and 5-me-dC to 5-me-C in the broods. Whether the DNA- to RNA-methylation ratio can be used as a biomarker, e.g., for reproductive toxicity in the Baltic amphipods needs to be investigated.

The Environment as a Reactor Determining Fate and Toxicity of Nanomaterials (II)

356

Determining the nanoparticle-algae interaction in the bioaccumulation process

A. Rivero Arze, N. Manier, R. Ramdhany, INERIS / Direction de Risques Croniques; A. Chatel, Catholic University of the West / UBL, Mer Molécules Santé; C. Mouneyrac, Université Catholique de lOuest / UBL, Mer Molécules Santé

The use of engineered nanomaterials (NMs) raises concern regarding their fate in environmental compartments and their potential effects on aquatic organisms. One of the singularities of these substances is their duality of action, both physical and chemical. In the chain of events leading to the occurrence of a deleterious effect, the interaction between a NM and a biological organism is one essential event. Therefore, understanding the links between the properties of NMs and the physical interaction phenomenon (adhesion, internalization) with aquatic organisms, is essential in a context of *a priori* hazard assessment and for the categorization of these substances within a regulatory purpose. This work aims at determining the interaction of various NMs with freshwater microalgae, to gain a better understanding of its implication in bioaccumulation and biological effect. Green algae with different cell wall composition were separately exposed to different NMs suspensions. Flow cytometry and microscopic observation showed evidence of NMs-algae interaction. A dose-dependent response is observed for every type of NMs and a cell wall specificity is showed. So far, two parameters were identified as having a major role in the NM-algae interaction: i) the cell wall composition, as each algae had a different response to the set of tested NMs; and ii) the NMs physic-chemical properties; because for a given algae cell wall type, a different degree of increased algal complexity was observed according to each NM.

The role of invertebrates in a tiered bioaccumulation testing strategy for engineered nanomaterials

S. Kühr, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Bioaccumulation and Animal Metabolism; B. Meisterjahn, N. Schröder, Fraunhofer Institute for Molecular Biology and Applied Ecology IME / Ecological chemistry; B. Knopf, Fraunhofer IME Institute for Molecular Biology and Applied Ecology / Environmental Specimen Bank and Elemental Analysis; R. Zeumer, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Bioaccumulation and Animal Metabolism; J. Klehm, Fraunhofer IMWS; L. Hermsen, Fraunhofer IME Institute for Molecular Biology and Applied Ecology Schmallenberg; D. Volker, German Environment Agency; K. Schwirn, German Environment Agency - UBA; C. Rauert, German Environment Agency Umweltbundesamt / International Chemicals Management; C. Schlechtriem, Fraunhofer IME / Department Bioaccumulation and Animal Metabolism

Due to the increasing usage of manufactured nanomaterials (MNMs) there is an mandatory need for testing the bioaccumulation potential of this materials within the regulatory frame of REACH. The bioaccumulation potential is usually expressed as bioconcentration factor (BCF) determined in flow-through studies with fish according to OECD 305 [1]. The increasing number of different MNMs would lead to an unrealistic workload for testings. Handy et al. 2018 [2] proposed a tiered aproach including stategies for the reduction of animals for in vivo testing. As part of this study, bioaccumulation tests were performed with a range of invertebrate organisms to elucidate the bioaccumulation potential of different MNMs. Based on the results obtained, bioaccumulation endpoints such as bioaccumulation factors (BAF) or biomagnification factors (BMF) are calculated and compared. The pros and cons of the different test systems are discussed. Bioaccumulation studies were carried out with silver MNMs (NM300K) and titanium dioxide MNMs (NM105). The test media containing the particles were applied in studies on the water flea *Daphnia magna*, the freshwater amphipod *Hyalella azteca* and the freshwater bivalve *Corbicula fluminea*. Both compounds showed different elimination behaviour which provide clear indications regarding the potential bioavailability of the test compounds. Bioaccumulation endpoints could be calculated, however, the presence of MNMs remaining in the gastrointestinal tract my confound the total burden measurement. Bioaccumulation studies with invertebrate species can be carried out as part of a tiered bioaccumulation testing strategy. However, test systems have differing suitability for testing MNMs which may require specific adjustments of the test systems or the use of additional analytical approaches to guarantee a sufficient data quality for regulatory assessment.

358

The benthic isopod Asellus aquaticus as a model biomonitor for metallic nanoparticle pollution in freshwater systems

I. O'Callaghan, T. Sullivan, University College Cork / School of Biological, Earth & Environmental Sciences

Metallic nanoparticles (MNPs) are uniform in size, easy to synthesise, and can be modified to enable binding to ligands or antibodies. They have been defined as "emerging contaminants" and may pose a threat to human life or the environment. There is concern that particles entering the environment may be bioaccumulated by organisms. It is of concern to the environmental scientist that the toxicity of MNPs may be altered by various processes. A biomonitor is a species that gives a measurable response, indicating a change in the surrounding environment. Some species are known to bioaccumulate heavy metal pollutants in the freshwater environment, including the benthic isopod, *Asellus aquaticus*. *A. aquaticus* is tolerant to various types of pollutants, widespread and abundant. The use of *A. aquaticus* as a biomonitor may be an ideal alternative to the current, costly, on-line methods of monitoring pollutants in freshwater systems. As the species bioaccumulates trace metals over its lifetime, it offers the possibility of quantifying a long-term average of otherwise hard-to-detect pollutants, such as MNPs, within the environment, with particular emphasis on bioavailable materials. This could be a crucial step towards implementing a cost-effective biomonitoring programme in locations which may not be easy to access for regular sampling. While a number of studies have considered the effects of pollutants on *A. aquaticus*, few have investigated the processes by which the species ingests, adsorbs, accumulates or excretes the pollutant. There is a great need for further modelling of the fate of MNPs in the environment, and while a model has been proposed for the uptake and accumulation of pollutants by benthic macroinvertebrates, that model does not take into account the process of moulting, as is undergone by *A. aquaticus* every 6-10 days. It has been suggested that moulting may be an adaptation of *A. aquaticus* to expel potentially harmful metals which have accumulated in the carapace, and so any model which is applied to the species must take this process into account. We present a case for the use of *A. aquaticus* as a cost-effective biomonitor for long-term averages of pollutants and a well-adapted method for the monitoring of inaccessible locations. We propose an expanded model for the uptake, excretion and bioaccumulation of metallic nanoparticles in a benthic macroinvertebrate. This model is species-specific, and accounts for the regular moulting of *A. aquaticus*.

359

Biodynamics of isotopically labelled CuO nanoparticles and dissolved Cu in the worm T tubifex: Comparing exposure routes

A. Thit Jensen, Roskilde University / ENSPAC; H. Selck, Roskilde University / Dept Science and Environment

Upon release into the aquatic environment, metal nanoparticles (NPs), such as CuO NPs will likely agglomerate/aggregate favoring their deposition onto sediments. Very little is known about the biodynamics of uptake of sediment-associated NPs in sediment-dwelling organisms, such as *Tubifex tubifex.* We used the biodynamic model to gain insights into differences in bioaccumulation dynamics between metal forms (aqueous Cu vs CuO NPs) and exposure routes (water vs sediment). The biodynamic model is a simple model that assumes that net bioaccumulation is a result of influx from diet and water and efflux, in the form of physiological loss (k_e) and growth dilution. Isotopically labelled ^{65}Cu was used to avoid confounding influence of background Cu and because it lowers the detection limit for both metal ions and metal NPs. Six different experiments (3 sediment and 3 waterborne exposures) were conducted to parameterize uptake and elimination of $^{65}CuCl_2$ and ^{65}CuO NPs (7 nm) in *T tubifex*. For each exposure route one uptake, one elimination and one net accumulation experiment were conducted for each metal form. Concentrations of newly accumulated ^{65}Cu in samples were determined based on measurements of the naturally occurring stable Cu isotopes (^{63}Cu and ^{65}Cu) using inductively coupled plasma-mass spectrometry (ICP-MS, 7900, Agilent). Our study showed that both $^{65}CuCl_2$ and ^{65}CuO NPs were bioavailable to *T tubifex* regardless of exposure route. Uptake rate constants from water (K_{uw}) was higher for $^{65}CuCl_2$ than for ^{65}CuO NPs (etimated K_{uw}s: 2.5 and 1.2 L g^{-1} d^{-1}, repectively). Similarly, upake rate constants for sediments (K_{us}) were higher for $^{65}CuCl_2$ than for ^{65}CuO NPs (estimated K_{us}s: 0.2 and 0.1, g g^{-1} d^{-1}, respectively), though weight specific body burden were similar for worms exposed to the two Cu forms. 14 d elimination following 3 d water exposures was similar between the two treaments with 59.2±21 and 58.8±17% ^{65}Cu retained for $^{65}CuCl_2$ and ^{65}CuO NPs, respectively (no significant differnce). 21 d of elimination, following sediment exposures was slightly higher for $^{65}CuCl_2$ than ^{65}CuO NPs with 38±18 and 48±9% ^{65}Cu retained, respectively (not significantly different). In summary, there was an overall trend that accumulation of ^{65}Cu in *T tubifex* was higher following exposure to $^{65}CuCl_2$ than ^{65}CuO NPs, especially for water exposures.

360
Detection of nano-sized particles in fish following an in vivo dietary exposure: a case study using silver nitrate, silver nanoparticles and silver sulfide nanoparticles
N. Clark, University of Plymouth / School of Biological and Marine Sciences; R. Clough, University of Plymouth / Analytical Research Facility, School of Geography, Earth and Environmental Sciences; D. Boyle, University of Plymouth / School of Biological and Marine Sciences; V. Sharma, R. Handy, University of Plymouth
The toxicity of nanomaterials may correlate with certain characteristics, notably the particle size and the number present in the tissue, emphasising the need for these measurements following exposures. Single particle ICP-MS (spICP-MS) has gained a lot of interest for determining the particle number concentration and particle size distributions in tissues. Here, we present data following an *in vivo* dietary exposure to $AgNO_3$, Ag NPs or Ag_2S NPs. Fish were fed an Ag-supplemented diet (100 mg total Ag/kg) for 4 weeks, followed by 2 weeks depuration. At weeks 2, 4 and 6, the hind intestine, kidney and liver were collected from fish. An alkali based extraction method was developed to remove the particles from the tissue matrix and analyse via spICP-MS. Particulate Ag was found in the hind intestine of all treatments, including the $AgNO_3$ treatment and trace amounts in the controls. At week 4, the particle number concentration (per g dw) in the hind intestine was $7.0 \pm 3.1 \times 10^7$, $31.8 \pm 11.7 \times 10^{10}$, $12.0 \pm 3.3 \times 10^{10}$ and $0.1 \pm 0.0 \times 10^{10}$, for the control, $AgNO_3$, Ag NPs and Ag_2S NPs, respectively. In the Ag treatments, both the $AgNO_3$ and Ag NPs were significantly higher compared to the Ag_2S NP treatment, showing a lower bioavailability of the latter material. Additionally, this indicates that particulate Ag can be made in either the gut lumen or within the intestinal tissue. There was no difference in the median particle size of the hind intestine or kidney of any Ag treatment (30-50 nm), suggesting the particles released from the intestine and circulate in the blood to other organs. Interestingly, in the liver, the median particle size of the $AgNO_3$ and Ag NP treatments significantly increase to around 80 nm compared to the controls (50-60 nm). Such increases in particle size suggests an agglomerative process or more complex ionic deposition to particles. In conclusion, fish can be exposed to particles from the gut lumen or tissue, which are subsequently released from the hind intestine into the circulatory system and enter other organs where particle transformation processes may (liver) or may not (kidney) occur. To support this spICP-MS data, whole organ proteome of the hind intestine and liver will be presented to determine sublethal toxicity. Additionally, these protein expression profiles will potentially inform on the form of Ag entering the intestine. This work was supported by an EC funded grant, NanoFASE (number 646002).

Removal of arsenic from contaminated seawater by manganese spinel ferrite nanoparticles: ecotoxicological evaluation in Mytilus galloprovincialis
F. Coppola, Department of Biology & CESAM - University of Aveiro / Biology; D.S. Tavares, CESAM University of Aveiro / Departament of Chemistry; B.M. Henriques, CESAM University of Aveiro and CIIMAR University of Porto / Department of Chemistry; A.M. Soares, University of Aveiro / department of Biology & CESAM; E. Figueira, University of Aveiro / Biology CESAM; T. Trindade, University of Aveiro / Department of Chemistry CICECO; E. Pereira, CESAM University of Aveiro; R. Freitas, University of Aveiro / Departamento de Biologia CESAM
In recent years, nanotechnology has developed new materials with several advantages in relation to traditional water treatment methods. For example, manganese-ferrite ($MnFe_2O_4$) nanoparticles (NPs) have a large specific surface area and many active sites, being very efficient sorbents for different potentially toxic elements in contaminated waters, including arsenic (As) that is currently listed as the top-priority hazardous substance by the Agency for Toxic Substances and Disease Registry. Moreover, due to its magnetic properties, $MnFe_2O_4$ NPs can be easily separated from water after treatment by applying a magnetic field. Recently, we optimized the synthesis of these NPs (and operational conditions) demonstrating that a small amount can reduce significantly the levels of As in contaminated water (>90% removal). In the present study we aimed to evaluate the ecotoxicological safety of the remediated water, which is common lack in most of the works. Mussels *Mytilus galloprovincialis*, which have been identified by several authors as a good bioindicator species that responds quickly to environmental disturbances, with spatial distribution and economic relevance were chosen as species model. Organisms were exposed for 28 days at 17ºC and salinity 30 to different conditions, including clean seawater (control); remediated seawater; As (1000 μg/L), $MnFe_2O_4$ NPs (50 mg/L) and mixture of both, with weekly water renewal. At the end of exposure, concentrations of As in mussels tissues were quantified and biomarkers related to mussels' metabolic and oxidative stress status were evaluated. Results revealed that mussels exposed to water contaminated with As and to As+NPs accumulated significantly more As than those exposed to the remediated seawater. Regarding biomarkers, our findings demonstrated that contaminated seawater clearly caused higher impacts in mussels than decontaminated seawater, with higher oxidative stress and lower metabolic capacity in mussels exposed to contaminated seawater.

Advances in Soil Ecotoxicology and Risk Assessment - Impact, Ecotoxicity Tests, and Concepts for a Retrospective Environmental Risk Assessment (II)

362
Effects of climate-related stressors on survival, reproduction and physiological state of the earthworm Eisenia andrei
C.S. Pereira, CFE - Centre for Functional Ecology / Department of Life Sciences University of Coimbra; A. Bednarska, Institute of Environmental Sciences, Jagiellonian University in Krakow / Institute of Nature Conservation; Z.M. Swiatek, Institute of Environmental Sciences, Jagiellonian Univeristy / Institute of Environmental Sciences; S. Chelinho, CFE Centre for Functional Ecology / Department of Life Sciences of University of Coimbra; J. Sousa, University of Coimbra - Centre for Functional Ecology / Department of Life Sciences; R. Laskowski, Institute of Environmental Sciences, Jagiellonian University in Krakow / Ecotoxicology & Stress Ecology Group
General estimations point to 1 billion hectares of salt affected areas and this number is expected to increase. Besides, the expected changes in precipitation regimes and the registered increase of 0.85ºC on surface temperature observed between 1880 and 2012, will probably enhance extreme events. A few studies on the effects of salinity or temperature and/or moisture on soil ecosystems have been conducted but their simultaneous effects on soil invertebrates has not yet been assessed. The present study aimed at evaluating the effects of three climate-related stressors, namely salinization, temperature and moisture, on the survival, reproduction and physiological state of the earthworm *E. andrei*. To fulfill such aim, the ISO earthworm reproduction test was performed to assess survival and reproduction, and a parallel 28-day test was carried out to assess the effect of above-mentioned stressors on the available energy reserves (*Ea*), i.e. lipid, carbohydrate and protein contents, and energy consumption measured at both the cellular level (*Ec*) and as the whole-organism respiration rate (*R*). A total of 27 treatments were tested, which included three levels of salinity (0, 24 and 31% of seawater), moisture (35, 50 and 70% of the water holding capacity, WHC), and temperature (20, 25 and 30ºC), in a full factorial design. Results showed that all three stressors, and their interactions influenced life-cycle parameters of the earthworms. Both salinity levels decreased survival at both 35 and 70% WHC and at all temperatures with the strongest effect at 30ºC. Similarly, both salinity levels decreased reproduction with the strongest effect found at 35% WHC. The reproduction was the lowest at 30ºC, but negative effect of salinity was found at all temperatures. The high mortality of earthworms at 35% WHC and 31% of seawater did not allow for testing the effects of all possible interactions between stressors on physiological endpoints. Nevertheless, decreased *R*in earthworms exposed for 28 days to 24% of seawater at 70% WHC was found at 20 and 25ºC. Coping with stressors,a decrease in energy reserves was expected. However, no significant impact on any component of *Ea*was found in those individuals which survived 28 days of exposure, probably due to different allocation of energy: the earthworms from lower-stress conditions reproduced, but those exposed to higher-stress conditions might use energy to meet the increased energetic demand to survive.

363
Do climate factors affect invertebrates' avoidance behaviour in anthropogenic-degraded soils?
C.C. Malheiro, Department of Biology, University of Aveiro / Biology; D. Nunes Cardoso, CESAM, University of Aveiro / department of Biology & CESAM; S. Loureiro, Universidade de Aveiro / Biology; M. González-Alcaraz, Department of Biology & CESAM - University of Aveiro / Biology & CESAM
The Intergovernmental Panel on Climate Change (IPCC) predicts major changes in future climate conditions. Soils will be among the most affected components of terrestrial ecosystems, especially in anthropogenic-degraded areas where soil biota has to deal with already multiple stressors. This study aimed at assessing the effects of different climate factors (soil moisture content, air temperature, ultraviolet radiation and atmospheric CO_2) on the avoidance behaviour of two invertebrate species (*Folsomia candida* and *Enchytraeus crypticus*) in anthropogenic metal(loid)-contaminated soils. Two soils degraded by metal(loid) contamination were selected in central-northern Portugal: mining soil; former agricultural soil near an industrial chemical complex. Lufa 2.2 soil was used as control soil. The avoidance behaviour of *F. candida* and *E. crypticus* was evaluated under different climate conditions: 20 ºC + 50% soil water holding capacity –WHC– (standard climate conditions); 20 ºC + 75% soil WHC; 20 ºC + 25% soil WHC; 15 – 25 ºC + 50% soil WHC; 20 – 30 ºC + 50% soil WHC; 25 – 35 ºC + 50% soil WHC; 20 ºC + 50% soil WHC + UV radiation (UVR) exposure; 20 ºC + 50% soil WHC + 600 ppm atm CO_2; 20 ºC + 50% soil WHC + 800 ppm atm CO_2; 20 ºC + 50% soil WHC + 1000 ppm atm CO_2. Both invertebrate species had different avoidance response towards the contaminated soils whether under standard climate conditions or when individual climate factors were changed. Under standard climate conditions *F. candida* showed a homogeneous distribution between the mining and control soils and a slight preference for the agricultural soil, while *E. crypticus* avoided both contaminated soils. When changing the

climate conditions *F. candida* maintained the same behaviour, except when exposed to higher atmospheric CO_2 levels in which organisms avoided metal(loid)-contamination. *E. crypticus* avoided both contaminated soils when changing the different climate factors evaluated, except when exposed to high (75% soil WHC) and low (25% soil WHC) soil moisture content. This study showed that both invertebrate species differed in their capacity to avoid anthropogenic metal(loid)-contaminated soils and that changing climate conditions may affect their avoidance response. *F. candida* only avoided metal(loid) contamination when exposed to high levels of atmospheric CO_2, while *E. crypticus* lost their capacity to avoid metal(loid)-contaminated soils when exposed to flooding and drought soil conditions.

364

Microbial communities in As contaminated agricultural soils -How PK fertiliser can influence As speciation

J. Hellal, N. Devau, P. Houllemare, C. Joulian, BRGM; H. Daniel, Bureau de recherches géologiques et minières (BRGM); M. LE GUEDARD, LEB AQUITAINE TRANSFERT-ADERA / LEB AQUITAINE TRANSFERT; F.F. Battaglia-Brunet, BRGM / Water, Environment and Ecotechnology Division

In 2018, 220 million people are still exposed to As from drinking water or food. When crops are grown on arsenic-rich soils, or irrigated with arsenic-containing water, agricultural products, such as rice, corn or barley can contain high arsenic levels, and the bio-accumulation may be linked to arsenic speciation. The present work, performed as part of the WaterJPI AgriAs project, focuses on the links between As concentration and speciation in soils, soil redox conditions and fertilization (PK) through the application of a range of microbial bio-indicators. In soils contaminated contaminated with As from the destruction of WWI weapons, soil microbial communities and abiotic parameters were measured. Soils were then incubated in oxic or anoxic conditions with increasing amounts of PK fertilizer to assess its impact on the fate of As. As concentrations on-site affect microbial communities with higher abundances of As-oxidising and reducing bacteria in the most contaminated soil. A PK amendment in oxic conditions favoured As speciation as AsV, as expected, and only reduced its mobility for the highest PK amounts, possibly due to mineral precipitation. In anoxic conditions however, the PK amendment significantly reduced As mobility although most of the As was AsIII. This could also be linked to mineral precipitations of phosphorus with As. These results are aimed to help provide recommendations to the EU for management of As-contaminated soils that present a risk to populations.

365

A lab-to-field approach to monitor the exposure of soil microbial communities to β-triketone herbicides

C. Thiour Mauprivez, University of perpignan; M. Devers-Lamrani, J. Béguet, INRA of Dijon / Agroecology; C. Calvayrac, University of perpignan / BAE; F. Martin-Laurent, INRA of Dijon / Agroecology; l. barthelmebs, University of perpignan

β-triketone herbicides are among the most used herbicides in corn crop. These herbicides inhibit the 4-hydroxyphenylpyruvate dioxygenase (4-HPPD), lead to bleaching and prevent the growth of broadleaf weeds. This enzyme is not only found in plants but in all living organisms, including microorganisms where it plays a role in the tyrosine degradation pathway. Thus, microorganisms classified as “non-target organisms” by current EU regulation for pesticide authorization, might be impacted by β-triketones, with consequences on microbial function supporting soil ecosystem services. Since microorganisms have been proposed by EFSA as key-drivers to protect soil ecosystem services, we suggest a novel approach consisting in considering the *hppd* bacterial community as a biomarker sensitive to the exposure to β-triketone residues. With this objective, we developed a toolbox to monitor the abundance, the composition, the diversity and the activity of the *hppd* bacterial community. Each method was tested in a lab-to-field experimental design following the tiered-approach recommended by EFSA to conduct pesticide environmental risk assessment (ERA). Under lab conditions, soil microcosms not exposed (control) or exposed to x1 or x10 the agronomical dose of sulcotrione (active ingredient) or Decano® (one of the commercial formulation of sulcotrione) were studied. Under field conditions, samples were collected in corn crop exposed to β-triketones. Soil samples were also collected from a non-treated corn field (not exposed control). Analytical chemistry was applied to all samples to search for β-triketone residues and to estimate the scenario of exposure of soil microorganisms. Nucleic acids (DNA/RNA) were extracted from soil samples to measure the abundance (quantitative PCR), the expression (quantitative RT-qPCR), the composition (α-diversity) and the diversity (β-diversity) (NGS) of the *hppd* bacterial community. Our results will be presented to the audience with the aim to identify the better proxy of the *hppd* bacterial community that could be used as a biomarker to reflect the exposure of soil microbial community to β-triketone residues. This explanatory work might be extended to other pesticides targeting other enzymes that are also present in so call non-target organisms such as sulfonylureas inhibiting acetohydroxy acid synthase (AHAS).

366

Efflux pump activity in Enchytraeidae

M. Kovačević, 1Department of Biology, University of Osijek / Department of Biology; D.K. Hackenberger, Department f Biology, University of Osijek / Department of Biology; . Lonńarî, Department of Biology, University of Osijek / Department of Biology; B.K. Hackenberger, Department f Biology, University of Osijek / Department of Biology

Enchytraeids are ecologically relevant soil organisms, which play an important role in organic matter decomposition and soil bioturbation. They live in close contact with the pore water fraction of soil which makes them vulnerable to xenobiotics exposure. MXR proteins (efflux pump) transfer certain groups of xenobiotics out of the cell and keep the intracellular concentration of these compounds low. They are present in all organisms, including microbes, plants, invertebrates and vertebrates. In the phylum Annelida MXR activity was discovered mainly in earthworm species but none enchytraeids. For the identification of MXR system activity fluorescent substrates are often used. In case of MXR system inhibition, the concentration of the substrate in the cells increases, and this can be seen as a rise in fluorescence. Enchytraeids were exposed in distilled and ISO test water, with or without specific inhibitors and inducers at various concentrations for 1 h in the dark. After pretreatment they were exposed to various concentrations of Rhodamine B (RhB) or Rhodamine 123 (Rh123). The measurement of RhB and Rh123 amount in samples were conducted immediately after centrifugation. The samples were kept in dark due to the photo degradation of RhB and Rh123. The amount of RhB and Rh123 in the samples was measured using spectoflourometer. Using RhB and R123 as the fluorescent substrate, it could be seen that different substrates and chemosensitizers have an effect on the amount of fluorescence in the *E. albidus* and *E. crypticus*. Some metal nanoparticles and pesticides are ubiquitous environmental toxicants and potential MXR modulators that pose a continuing risk to many non-target species. The ability of enchytraeids to remove the xenobiotics from the cells will greatly impact the final harmful effects. Determining presence and function of the MXR in enchytraeids can help us to understand the consequences of MXR inhibition at the population and ecosystem level. This study shows that enchytraeids, as a model species in terrestrial ecotoxicology, possess MXR activity and that different substrates and chemosensitizers have an impact on it. Therefore, it can be presumed that xenobiotics present in the environment will have an effect on MXR system as well. Due to the influence of MXR activity on bioaccumulation and toxicity of various compounds, the assessment of MXR activity could be a valuable complementary biomarker in ecotoxicological research and risk assessment.

367

Earthworm avoidance behavior quantification using artificial neural networks

T. Djerdj, Department of Biology, University of Osijek / Department of Biology; D. Hackenberger, BioQuant d.o.o.; D.K. Hackenberger, B.K. Hackenberger, Department f Biology, University of Osijek / Department of Biology

Avoidance behavior of earthworms represents a valuable endpoint in ecotoxicological studies examining the\neffects of sub-lethal concentrations of pollutants on soil-dwelling fauna. Since it was first performed by\nYeardley (1996), the earthworm avoidance test was proven to give ecologically relevant insights into modes\nof action of various pollutants. Since behavioral responses of test organisms are highly variable over time,\ndevelopment of techniques that would allow continuous monitoring of avoidance behavior are of great\nimportance.\nIn this research, a novel approach is presented towards developing a low-cost, automated monitoring method\nfor continuous examination of earthworm behavior within avoidance tests. The suggested system\nimplements a 2D terrarium, a tool widely used in earthworm behavioral studies, as a compartment in which\nthe avoidance test is performed. Automatization of avoidance behavior detection analysis is achieved using a\ndeep convolutional neural network model, constructed and trained in Keras, that gives precise predictions of\nearthworm locations in images of both sides of the terrarium during the test period. To quantify the motion of\nthe experimental organisms in 2D space, the area of the terrarium is divided into multiple segments.\nPerformance of the presented system was tested in avoidance tests performed in glass terrarium filled with\nclean artificial soil in one half and artificial soil spiked with oil mill waste in the other half. Predictions of\nearthworm location probabilities over the image-pairs show high level of overlap, complementing each other\nand increasing certainty of automatic earthworm location determination. The first period of the experiment is\ncharacterized by equal presence of earthworms in both halves of the terrarium, with a gradual shift from the\nbottom to the top layers. Thereafter, a transition to the unpolluted (control) half is observed. This period of\nthe experiment is characterized by the localization of earthworms in the bottom half of the control soil.\nThe presented ANN-based approach proved to be useful in continuous monitoring of earthworm behavior.\nDue to its low cost and simple design, it is an easily reproducible setup that gives a significant acceleration to\nanalysis and interpretation of data resulting from behavioral studies, with the potential of becoming an ultimate\ntool in research of primary modes of action of various pollutants present in the environment.

Adverse Effects of Chemicals on Host-associated and Free-living Microbiomes (I)

Effects of microcystin and extracts from toxin-producing cyanobacterial strains on the gut microbiota of medaka fishes (Oryzias latipes) : a microcosm approach

S. Duperron, Muséum National dHistoire Naturelle / UMR7245 MCAM; M. Habiballah, A. Gallet, MNHN; H. Huet, ENVA; C. Duval, Muséum National dHistoire Naturelle / UMR7245 MCAM; C. Bernard, MNHN / Cyanobactéries Cyanotoxines et Environnement; B. MARIE, Muséum National dHistoire Naturelle / UMR7245 MCAM

The importance of animal-associated microorganisms in various aspects of host biology is increasingly recognized, and contributes innovative lines of research in various areas of life sciences. Sit at the interface between an organism and its environment, the microbiota must be accounted for in ecotoxicology studies, as much as the host organism itself. The effect of toxin-producing cyanobacterial blooms on fishes health has been extensively investigated, yet no study to date has evaluated this effect of fish-associated microbiota. In this first effort to document this effect, we exposed a model fish, the medaka *Oryzias latipes*, to pure microcystins and to crude extracts of metabolites from cyanobacterial cultures in order to test their influence on microbiote composition. Histology approaches were used to estimate the impact of toxins on fish liver and to evaluate the density of bacterial communities present on the gill, skin and gut of fishes. Metabarcoding approaches using the 16S rRNA-encoding gene were used to investigate bacterial community composition at the individuals level. We show that fish gut harbors the highest bacterial densities. Gut-associated communities differ from those in the water, and among individual fishes. Exposure to extracts, rather than pure microcystin, has a significant influence on gut community compositions. We suggest that compounds present in the cyanobacterial extracts, but not microcystin alone, alter the composition of bacterial communities, with possible consequences for the digestive function of fishes. Based on this very simple microcosm setup, we propose that the effect of cyanobacterial blooms on fish gut microbiota and associated functions, including toxin degradation and feed efficiency, should be further explored.

Effect of triclosan on benthic microbial communities in aquatic ecosystems: a microcosm study

L.M. Schuijt, Wageningen University; H. Smidt, Wageningen University / Laboratory of Microbiology; P. van den Brink, Wageningen Environmental Research

Aquatic ecosystems receive a wide range of pollutants such as pesticides, pharmaceuticals and personal care products. One of the pollutants that can be found in aquatic ecosystems is triclosan, a synthetic antibacterial compound which inhibits the enzyme enoyl-ACP reductase, essential in the bacterial fatty acid biosynthetic pathway. Due to its antimicrobial properties, triclosan may negatively affect the abundance, diversity and activity of benthic microorganisms. Since microorganisms are essential for aquatic ecosystems, carrying out crucial ecosystem functions such as decomposition, nutrient cycling and primary production, it is pivotal to understand the pollutant-induced effects for the protection of those systems. We used a microcosm approach to assess the effects of triclosan on benthic microbial communities of natural and artificial sediment in situ colonized by microorganisms of two different waterbodies. More specifically, we (1) evaluated how microbial communities respond to exposure of triclosan, (2) assessed whether those responses differ between waterbodies and (3) evaluated whether we can use in situ colonized artificial OECD sediment in the assessment of pollutants on microbial communities. We exposed microcosms to different triclosan concentrations for 7 days in the laboratory. These microcosms contained natural sediment collected from two non-contaminated waterbodies and artificial sediment inoculated at those two sites. HiSeq sequencing of the V4 region of archaeal and bacterial 16SrRNA gene was used to characterize the microbial communities for the different treatments. Initial results of the microcosms containing artificial sediment inoculated in a ditch do not show clear effects of triclosan on microbial diversity and community structure. However, in addition we will analyse the samples by qPCR to determine the abundance of total bacteria (16S rRNA gene) and analyse the other three sediment treatments.

370

The effects of biocidal nanoparticles on the midgut bacterial community and immune responses in earthworms

E. Swart, T. Goodall, L. Newbold, Centre for Ecology & Hydrology; P. Prochazkova, J. Dvorak, Institute of Microbiology of the CAS, v.i.i.; S. Hernádi, P. Kille, Cardiff University; D. Spurgeon, Centre for Ecology & Hydrology; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology

A major application of nanoparticles (NP) is as an antimicrobial agent in paints, coatings and pesticides. As the microbiome of animals can play an essential role in the health of their host, the release of biocidal NP into the ecosystem might lead to adverse health effects in animals should their microbiome be negatively affected by exposure to a biocide. This paper studies the impact of biocidal metal NPs on the bacterial community composition in soil and the midgut of the earthworm *Eisenia fetida*. Additionally, host immune responses to a biotic challenge under NP exposure are also assessed in order to study the implications of sublethal NP exposure on host health. To study the impact of biocidal NPs on the midgut bacterial community, two 28-days long exposures were conducted, one using copper oxide NP, the other using silver NP. At the end of the exposure, the community composition in the soil and the earthworm midgut was assessed by amplification and sequencing of the 16S-rRNA gene. To study host immune responses under sublethal NP exposure, earthworms were exposed to either copper oxide NP, ionic copper or negative control for 28 days and subsequently exposed to either a high dose of *Bacillus subtilis* or a negative control before returning to the original exposure soils for recovery. Five sampling points were selected throughout the experiment. At each sampling point, the bacterial community composition of the soil and the earthworm midgut was assessed as well as the expression of various immune genes in earthworm midgut tissue and coelomic fluid. The data show that copper NPs cause a significant shift in the bacterial community composition in the soil and the earthworm midgut. The most dominant core midgut taxa are hardly affected by the exposure. However, the relative abundance of certain core taxa including *Candidatus* Lumbricinola and a *Spirochaetacaea* are significantly reduced under copper exposure. Exposure to silver NP caused a strong shift in the soil bacterial community but no significant effect of silver NP on the midgut bacterial community was recorded. All samples from the experiment assessing host immune responses to a bacterial challenge under NP exposure have been collected and results will be included in the presentation. This study shows that biocidal metal NP can induce community changes in microbiome of earthworms with the possible loss of some core bacterial taxa at copper levels frequently reported in agricultural soils.

371

Multi-omics approach to determine the effect of bis(2-ethylhexyl) phthalate on microbiome-gut axis

O. Adamovsky, Masaryk University, RECETOX / Department of Physiological Sciences; A. Buerger, University of Florida / Environmental and Global Health; H. Vespalcova, S. Smatana, E. Budinska, Masaryk University / Research Centre for Toxic Compounds in the Environment RECETOX; J. Bisesi, University of Florida / Environmental and Global Health; C.J. Martyniuk, University of Florida / Physiological Sciences

Phthalate esters, such as DEHP (bis(2-ethylhexyl) phthalate, are a ubiquitous class of chemicals used as plasticizers in plastic products such as toys and hospital supplies. They are not covalently bound to the polymer matrix and can leach out of products. Experimental studies suggest that microbiome and gut play significant role in metabolism and disruption of microbiome-gut axis leads to effects on intake of nutrient, hormone balance, immunity and nervous system. The goal of this study is to determine whether DEHP, a model metabolic disruptor, adversely affect the zebrafish (*Danio rerio*) microbiome-gut axis and describe how taxonomical change in microbiome are reflected in gut. We exposed the fish to 3 ppm DEHP via food for 8 weeks to stimulate chronic exposure. Fish were fed once a day with commercial food mixed with DEHP. Fish were dissected and the content of gut and the gut tissue were collected and flesh frozen. The composite and diversity of microbiome were studied by analyzing of 16s RNA genes using Illumina MiSeq. Subsequently, we link the phylogeny and the function of the microbiome using a bioinformatics approaches. To identify genomic responses of DEHP in gut, we used microarray and real-time RT-PCR analysis followed by differential gene expression analysis. The data were then mapped to changes in cell processes and signaling pathways using Pathway Studio. This study revealed, that DEHP can significantly effects the composition of microbiome and its related function, and that these microbial changes together with the direct effect on gut has an effect on gut's transcriptome. Interestingly, the changes on gut and microbome are different for both sexes. The aim of this presentation is to present the microbiome-gut axis as a target for metabolic disruptors, such as DEHP and emphasize the need of multi-omics approach to study this phenomenon. This research was supported by Marie Sklodowska-Curie actions no.707241, by CETOCOEN PLUS (CZ.02.1.01/0.0/0.0/15_003/0000469) and RECETOX RI (LM2015051).

Early-life exposure alters copper tolerance in the stickleback gill microbiome

T. Uren Webster, Swansea University / Department of Biosciences; L.V. Laing, University of Exeter / Biological Sciences; J.A. Fitzgerald, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology; N. Bury, University of Suffolk / School of Science, Technology and Engineering; H. Littler, E.M. Santos, University of Exeter / Biosciences College of Life and Environmental Sciences

The microbiome influences host phenotype in many ways. While stress-disruption of the microbiome may induce adverse health effects on host health, metagenomic plasticity may represent a potential mechanism of stress-tolerance in natural fish populations. We investigated the effect of copper, a widespread environmental pollutant, on the gill microbiome of the three-spined stickleback (*Gasterosteus aculeatus*). We aimed to characterise the impact of environmentally-relevant

concentrations of copper on the gill microbiome of adult stickleback, and also to investigate whether pre-exposure to copper in early life affected later-life microbiome copper-tolerance. We exposed stickleback embryos/larvae to either 0 or 10 μg/L copper from 1-217 hpf, grew fish to sexual maturity under control conditions, and then re-exposed adult fish from each group to either 0, 10 or 20 μg/L copper for four days. Gill microbial community profiling was performed using 16S rRNA amplicon sequencing (V4 region), with OTUs assembled and annotated using mothur and Silva reference data. We found that adult exposure to copper had little impact on gill microbial Chao1 richness or Shannon diversity, but did have a clear effect on microbiome structure. Exposure to 20 μg/L copper induced a significant change in community structure relative to control (unexposed) fish, regardless of pre-exposure. This change was characterised by a significant increase in the abundance of several OTUs with known copper tolerance, including *Deinococcus* sp., and also induced a marked change in predicted community function. In contrast, the effects of exposure to 10 μg/L copper were strongly influenced by pre-exposure in early life. While fish that were not pre-exposed to copper showed similar structural and functional changes to those identified in the higher copper treatment group (20 μg/L), the fish that had been pre-exposed to copper displayed gill microbiome structure more similar to the control (unexposed fish). Overall, we have shown that copper exposure induces structural and functional changes in the gill microbiome, and these may potentially also influence host phenotype. However, our results also suggest that pre-exposure to copper during early development can increase microbiome copper-tolerance in later life which may, potentially, also influence host tolerance of copper.

The Microbiome Stress Project: towards a global meta-analysis of environmental stressors and their effects on microbial communities

M. Simonin, Duke University / Biology; J.D. Rocca, Duke University / Biology department; J.R. Blaszczak, Duke University / Biology; J.G. Ernakovich, University of New Hampshire / Biology; S.M. Gibbons, Institute for Systems Biology; F.S. Midani, Duke University / Center for Genomic and Computational Biology,; A.D. Washburne, Montana State University / Department of Microbiology and Immunology

Microbial community structure is highly sensitive to natural (e.g. drought, temperature, fire) and anthropogenic (e.g. heavy metal exposure, land-use change) stressors. However, despite an immense amount of data generated, systematic, cross-environment analyses of microbiome responses to multiple disturbances are lacking. Here, we present the Microbiome Stress Project, an open-access database of environmental and host-associated 16S rRNA amplicon sequencing studies collected to facilitate cross-study analyses of microbiome responses to stressors. This database will comprise published and unpublished datasets re-processed from the raw sequences into exact sequence variants using our standardized computational pipeline. Our database will provide insight into general response patterns of microbiome diversity, structure, and stability to environmental stressors. It will also enable the identification of cross-study associations between single or multiple stressors and specific microbial clades. Here, we present a proof-of-concept meta-analysis of 606 microbiomes (from nine studies) to assess microbial community responses to: (1) one stressor in one environment: soil warming across a variety of soil types, (2) a range of stressors in one environment: soil microbiome responses to a comprehensive set of stressors (incl. temperature, diesel, antibiotics, land use change, drought, and heavy metals), (3) one stressor across a range of environments: copper exposure effects on soil, sediment, activated-sludge reactors, and gut environments, and (4) the general trends of microbiome stressor responses. Overall, we found that stressor exposure significantly decreases microbiome alpha diversity and increases beta diversity (community dispersion) across a range of environments and stressor types. We observed a hump-shaped relationship between microbial community resistance to stressors (i.e. the average pairwise similarity score between the control and stressed communities) and alpha diversity. We used Phylofactor to identify microbial clades and individual taxa as potential bioindicators of copper contamination across different environments. Using standardized computational and statistical methods, the Microbiome Stress Project will leverage thousands of existing datasets to build a general framework for how microbial communities respond to environmental stress

Novel Developments in Testing Chemicals for Endocrine Disrupting Properties (I)

Jensen, U.S. EPA / Mid-Continent Ecology Division; M. Kahl, U.S. EPA / National Health and Environmental Effects Research Laboratory; A. Kittelson, ORISE at US EPA; C. LaLone, U.S. EPA / Mid Continent Ecology Division; S. Poole, US EPA Mid-Continent Ecology Div / National Health and Environmental Effects Research Laboratory; E. Randolph, EPA / National Health and Environmental Effects Research Laboratory; C. Tilton, U.S. EPA / ORD; D.L. Villeneuve, U.S. EPA / National Health and Environmental Effects Research Laboratory

Quantitative adverse outcome pathways (qAOPs) describe quantitative response-response relationships linking the molecular initiating event (MIE) and adverse outcome (AO) to enable quantitative prediction of the probability of occurrence or severity of an AO for a given magnitude of chemical interaction with an MIE. A qAOP has been developed for inhibition of cytochrome P450 aromatase (CYP19) leading to reproductive dysfunction through decreased circulating estradiol (E2) thereby reducing circulating vitellogenin (VTG). This qAOP was developed based on quantitative data from the fathead minnow (*Pimephales promelas*). However, whether a qAOP developed based on data from fathead minnow could predict reproductive dysfunction in other fishes was unknown. Therefore, this study investigated whether this qAOP could accurately predict adverse responses to the model CYP19 inhibitor fadrozole for three other fishes, namely Japanese medaka (*Oryzias latipes*), zebrafish (*Danio rerio*), and mosquitofish (*Gambusia affinis*). Japanese medaka and zebrafish have asynchronous oocyte development in common with fathead minnow. In contrast, mosquitofish have group-synchronous oocyte development which is the prominent strategy among fishes. *In vitro* CYP19 inhibition assays demonstrate comparable sensitivities to fadrozole among fathead minnow, Japanese medaka, and zebrafish, while CYP19 of mosquitofish is 13-fold more sensitive. Results of 21-day reproductive assays demonstrate comparable quantitative response-response relationships describing fadrozole to E2, E2 to VTG, and VTG to egg production among the asynchronous fishes. However, mosquitofish have complex profiles of sex steroids and steroidogenic enzymes characteristic of group-synchronous oocyte development and exposure to fadrozole causes compensatory responses unique from asynchronous fishes. Overall, these results suggest that the qAOP developed for fathead minnow can broadly predict reproductive dysfunction among fishes with asynchronous oocyte development, which includes numerous small-bodied fishes. But, fishes with group-synchronous oocyte development have different compensatory responses and other modeling challenges which require further investigation towards development of an applicable qAOP. The results of this study could be essential in guiding more objective ecological risk assessments of fishes to aromatase inhibiting chemicals.

The direct link between endocrine MoA and adverse effect - Concepts to integrate molecular information in endocrine disruptor testing

E. Eilebrecht, M. Teigeler, Fraunhofer IME / Ecotoxicology; C. Schaefers, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Ecotoxicology

To be defined as endocrine disruptor, a substance has to meet several criteria, including the induction of specific adverse effects, a specific mode of action (MoA), and a plausible link between both. In order to prove causality, we applied different approaches, which utilize the Adverse Outcome Pathway (AOP) concept. We demonstrated that AOPs, in this case the AOP for Aromatase inhibition leading to reproductive dysfunction in fish, can be transferred to other life stages, and also other species. Indentical molecular initiating events (MIEs) and key events (KEs), as well as their relationships (KERs) are responsible for specific effects in different life stages. Thus, similar screening methods might be applied for the prediction of different, endocrine-related adverse effects, like reproduction in adult fathead minnow and a skewed sex ratio in juvenile zebrafish. Presumably sexual endocrine-related effects might also be triggered by other MIEs, belonging for example to endocrine and non-endocrine AOPs. Identification of these differences is of mayor importance, as regulation of endocrine disruptors is based on hazard assessment, while for non-endocrine substances a risk assessment has to be performed. Tests with fish performed according to OECD test guidelines are often noch able to identify the mode aof action of a sbustance, as only apical endpoints, which could be triggered by substances with different MoAs, are assessed. AOPs for these different MIEs are existing; however, the data gap has to be closed by methods not routinely applied in risk and hazard assessment. For example molecular signatures, which are MIE-specific rahter than substance-süecific, can be identified by high-content approaches like proteomics or RNAseq. We applied this approach in order to discriminate the AOP of aromatase inhibition form the AOP of hepatotoxicity during the reproductive pahse of adult zebrafish. Already the number of regulated proteins/genes in the respective tissues can give hints to the most affected organ. Furthermore, a deeper liik into the signaling pathways and into specific regulated proteins allow the identification of biomarkers, which can be further developed to be applied in *in vitro* screening tests, e.g. with zebrafish embryos.

376

Ambient temperature modulates biological effects of estrogenic exposure in

freshwater fish

H.L. Schoenfuss, St. Cloud State University / Aquatic Toxicology Laboratory; J.L. Ward, Ball State University / Dep of Biology

In ectothermic organisms, growth, reproduction, and behavior are mediated by changes in ambient temperature. Because the molecular mechanisms underlying such biological rhythms are closely integrated with the hypothalamus-pituitary-gonadal axis, environmental signals such as ambient temperature may modulate the effects of endocrine disrupting compounds in aquatic environments. In a series of four month-long experiments, we exposed larval and adult fathead minnows to three concentrations of estrone (E1) at four temperatures experienced during the breeding season (15, 18, 21, 24ºC). E1 concentrations represented ecologically relevant (E1-L 14ng/L; E1-M 22ng/L) or worst-case environmental scenarios (E1-H 65ng/L estrone). Larval fish were assessed for survival, growth and performance in predator avoidance and foraging assays, respectively. Reproductive, behavioral, morphometric, and physiological endpoints were tracked in adult fish maintained in breeding groups of one male and two females. We observed significant interactions between E1 concentration and temperature that influenced larval escape velocity and foraging performance, especially at lower temperatures. Adult survival, clutch size, and female morphological endpoints also experienced temperature modulation of E1 exposure effects. Our data suggest that the effects of contaminants can vary with thermal regime, especially at colder temperatures and in female fish. In addition, earlier life stages are more susceptible to the modulating effects of temperature on anthropogenic stressors. This study adds evidence that even under constant conditions that diverge from standard laboratory protocols, the expression of biomarkers consistent with exposure to endocrine disrupting compounds may change.

377

Endocrine potential of a small German stream influenced by a large WWTP - a combined assessment with cell-based and organism-based methods

Y. Mueller, RWTH Aachen University / Department of Ecosystem Analysis ESA; S. Oster, A. Shuliakevich, RWTH Aachen University / Institute for Environmental Research; K. Kaufmann, L. Blank, M. Agler-Rosenbaum, RWTH Aachen University; S. Schiwy, H. Hollert, RWTH Aachen University / Institute for Environmental Research

Not all European surface waters will reach the goal of the European Water Framework until 2027. One reason might be the release of a variety of anthropogenic micropollutants (MPs). They could be released via point sources as waste water treatment plants (WWTPs). Not all MPs are completely eliminated in the conventional treatment process and thus enter the aquatic environment. The implementation of a further treatment step, e.g. ozonation, could reduce this burden. A commercial scale ozonation plant was implemented at the “Aachen Soers” WWTP in 2017. It releases its effluent into the stream Wurm. To elucidate the impact of the additional treatment step, the *status quo* was recorded before and after the implementation. Beside numerous endpoints one important endpoint is the endocrine activity, which was evaluated by different CALUX® assays ((anti-)estrogenic, (anti-)androgenic), and by the reproduction assay with *Potamopyrgus antipodarum*. Samples up- and downstream the WWTP and the WWTP outlet were assessed. Results before upgrading have shown a reduced estrogenic potential downstream compared to upstream the WWTP. In contrast, there was a reduced embryo number upstream. There is no clear explanation, except the reduced measured temperature. Additionally, the embryo number was increased downstream compared to samples upstream and to the control. The temperature downstream the WWTP outlet was similar to the laboratory control, hence an effect by MPs could be most reasonable. But, also other environmental factors might have an influence. Anti-androgenic activity was measured at all sampling sites before upgrading. Anti-estrogenic activity was slightly higher downstream the WWTP. First results after implementation of the WWTP are available and will be finished until May 2019. Up to now, the study has shown, that cell-based bioassays are a good screening tool for endocrine activity, but also environmental factors can have a high impact on effects in organisms. Combining cell-based and organisms-based bioassays is a good choice to get a comprehensive picture of the environmental situation. Additionally, it is also necessary to measure not only the estrogenic but also other endocrine potentials to get a full picture of the chemical impact. *Acknowledgement* - The authors thanks the German Ministry for Climate Protection, Environment, Agriculture, Conservation and Consumer Protection of North Rhine-Westphalia for funding the DemO$_3$AC -project.

Breaking down the wall between human health and environmental testing of endocrine disrupters EndocRine Guideline Optimisation (ERGO)

H. Holbech, University of Southern Denmark / Biology; H. Hasler-Sheetal, SDU; T. Braunbeck, COS University of Heidelberg / Aquatic Ecology and Toxicology; L.A. Baumann, University of Heidelberg / Aquatic Ecology and Toxicology; J. Arning, German Environment Agency UBA; G. Schuurmann, Helmholtz centre for environmental research - UFZ / Department of Ecological Chemistry; D. Knapen, University of Antwerp / Zebrafishlab Dept Veterinary Sciences; L. Vergauwen, University of Antwerp / Zebrafishlab Dept Veterinary Sciences & SPHERE Dept Biology; F. flamant, Ecole Normale Normale Superieure de Lyon; M. Reuver, AquaTT

The authors present a new approach that will support a paradigm shift in the regulatory use of standardized test guidelines (TGs) by breaking the existing wall between mammalian and non-mammalian vertebrate testing and assessment of endocrine disrupting chemicals (EDCs). The highly conserved thyroid system will be used as the “proof of concept”, but also other conserved endocrine axes/systems such as the Retinoid X Receptor (RXR) and the Hypothalamus Pituitary Gonadal (HPG) axis can be adapted to the cross-vertebrate class approach. The project, called ERGO, will investigate a battery of draft in vitro assays and evaluate thyroid-responsive biomarkers and endpoints suitable for extrapolation of effects from fish and amphibian tests to humans and other mammals (and vice versa) and finally validate successful biomarkers and endpoints for inclusion in existing in vivo or new in vitro OECD TGs. A cross-class adverse outcome pathway (AOP) network will provide the scientifically plausible and evidence-based foundation for the selection of biomarkers and endpoints in lower vertebrate assays predictive of human health outcomes. In silico modeling and biotransformation data will support cross-vertebrate class effect extrapolation. Here we present the background and expected major outcomes of ERGO. An EDC project Cluster consisting of ERGO and 7 sister projects funded under EU Horizon2020 will also be presented and discussed. This Cluster represents the largest investment in EDC research ever funded in Europe and runs from 2019-2024.

Using population modelling to assess population relevance of endocrine-mediated effects of plant protection products in non-target vertebrates

L.L. Lagadic, Bayer Ag / Environmental Safety; K. Bentley, DuPont Crop Protection; M. Crane, AG-HERA; N. Galic, Syngenta Crop Protection LLC / Environmental Safety; N. Hallmark, Bayer AG Crop Science Division; O. Körner, ADAMA Agricultural Solutions / EU Registration; K. Ott, BASF SE; D. Pickford, Syngenta / Environmental Safety; T. Preuss, Bayer AG Crop Science Division / Environmental Safety; B. Sharma, FMC Agricultural Solutions / Global Regulatory Sciences; H. Thompson, Syngenta Ltd / Environmental Safety; P. Thorbek, BASF SE / Global Ecotoxicology; L. Weltje, BASF SE / Crop Protection Ecotoxicology; J.R. Wheeler, Corteva Agriscience The Agriculture Division of DowDuPont

European Commission´s hazard-based criteria to identify the endocrine disrupting properties of plant protection products (PPPs) applied across the European Union from 10th November 2018 (EC 2018). The implementation of this approach is supported by a Guidance Document (ECHA/EFSA 2018). For non-target organisms, a PPP active substance that meets the criteria is considered as having endocrine disrupting properties unless there is evidence demonstrating that the ED-related adverse effects identified are not relevant at the population level. According to EC (2018), the evaluation of population-relevant effects shall consider adequate, reliable and representative field or monitoring data and/or results from population models where available. However, in the Guidance Document, EFSA/ECHA considers that setting general rules for the evaluation of field studies and monitoring data is complicated, resulting in case-by-case evaluations. EFSA/ECHA acknowledges the existence of different population models that can be used for different purposes and for answering different questions such as the degree of reproductive impairment which is likely to trigger consequences at the population level. However, the Guidance Document does not provide recommendations on how population models should be used to assess population-relevant adversity in a hazard-based assessment. In this presentation, we describe a generic and modular modelling framework which complement this Guidance and would assist registrants and regulatory authorities to identify substances for which a potential endocrine disruption issue could be concluded from laboratory toxicity tests, but which would not translate into adverse effects on wildlife populations. The concept of Maximum Tolerated Concentration/Dose (MTC/D) and the concept of focal species are addressed, and we explain the conditions in which Dynamic Energy Budget (DEB) models can be combined to Individual-Based Models (IBM) without accounting for individual exposure. \n

Improving Decision Support for Sustainability Going beyond Standard LCA (I)

380

Closer than ever to seamless exchange of data and models between LCA software tools: lessons learned and improvement opportunities from the EF Remodeling project

M. Vieira, K. Cenian, PRe Sustainability; A. Ciroth, GreenDelta GmbH; M. Dupriez, RDC Environment; A. Genest, ifu Hamburg; S. Schulz, thinkstep AG / GaBi BU; M. Wolf, maki Consulting GmbH; E. Mieras, PRe Sustainability

Similar data and methods are implemented in various LCA software (SW) tools, however there are cases of the same dataset generating different results in different tools. Also, users tend to use one SW tool and when they want to move their data or model to another SW, they face many obstacles. In the context of the Environmental Footprint (EF) pilot phase, the European Commission requested the development of 63 representative products/organisations (RPs/ROs), which: are consistent with the requirements of the final product environmental footprint category rules (PEFCRs) and organization environmental footprint sector rules (OEFSRs), use the prescribed EF-compliant secondary datasets, and can be made available for free to any user applying a PEFCR/OEFSR and are easily usable in the major existing LCA SW tools. An implicit prerequisite is that SW tools calculate equal results for the same RPs/ROs. The remodeling project included five software tools: GaBi, openLCA, RangeLCA, SimaPro, and Umberto. 59 aggregated datasets, one for each representative product, developed in the ILCD format, were tested in all five SW tools. Already for a rather simple task, i.e. to calculate LCIA results for one aggregated dataset, a few iterations were needed – to align on flow mappings, LCIA method implementation, etc. – but ultimately all five SW tools calculated LCIA results with a difference lower than 1%. Because the ILCD format is limited to single process datasets, we developed a life cycle model (eILCD) format aimed at facilitating model exchange among the tools. Seven models, developed in four SW tools, were tested by all partners. Some models could be successfully exchanged between SWs and a few provided equal LCIA results, but not all of them. This presentation will cove: the problems faced when importing the models and investigating the sources of differences in the results in the different SW tools, as well as suggestions on how to address the import problems and results differences. This work is the basis to enable the reduction of software-system related issues. We believe this is a crucial step towards the exchange of data and models across SW tools and the comparability of results. We are definitely closer to that than we have ever been before… so we can't stop now. We need to capitalize on the work done and on lessons learned during the Remodeling project and improve what we have so far to ultimately make data and model exchange truly possible for all users.

381

Incorporation of hybridised impact assessment methods into LCA for the environmental evaluation of bio-based products

K. Lokesh, University of York / Department of Chemistry; X. Bengoa, V. Rossi, Quantis; L. Summerton, University of York

Adoption of bio-based products has been identified as one of the most promising pathways to establishing a sustainable and fully-functional bioeconomy. With an ever-increasing demand for bio-based products in the commercial market and public perception of instinctively associating bio-based products to being "sustainable" from cradle-grave, there is now a need for the sustainability communities to identify ways of mapping the threats and opportunities embedded in a given product and the process. The aim of this study is to propose and test the effectiveness of methodologies that incorporate the principles of sustainable consumption and production (SDG 12), resource efficiency and circular economy into conventional and holistic life cycle assessment to enable a fairer comparison of bio-based products and fossil-based products. The proposed hybridised cross-functional indicators were developed combining life cycle indicators with that of industrially-applied green chemistry resource efficiency metrics, also incorporating the principles of circular economy. The effectiveness of these methodologies was assessed via an exemplary comparative LCA of bio-based PLA packaging films with a fossil-based commercial equivalent from manufacturing to end of-life phases. In addition to the conventional impact indicators including land-use, freshwater and terrestrial eutrophication, water scarcity, fossil-resource use, acidification, quantitative and qualitative hybridised indicators such as hazardous chemical use, waste factor, secondary resource efficiency, energy efficiency and circularity have also been applied. The methodologies provided a unique dimension to the sustainability evaluation of bio-based products in terms of highlighting some of the "easy to interpret" impacts, particularly waste generation, material and energy efficiency of the product and process in question.

How to simplify the assessment of life cycle impacts for new organic reactions? Development of a tool and application to a catalytic reaction.

J. GICQUIAUD, University of Bordeaux / Institut des Sciences Moléculaires; P. Loubet, University of Bordeaux / ISM CyVi; P. Toullec, University of Bordeaux ISM UMR; G. Sonnemann, University of Bordeaux / The Life Cycle Group CyVi

Growing concerns regarding the diminishing of feedstocks and energetic resources and increasing environmental pollution problems have led the chemical community to redefine its way of thinking to an approach to a vision directed towards sustainable development. In this context, modern chemistry is developing around the concept of "Green Chemistry". Since 90's, simplified metrics such as the E-factor is used. Such metrics are limited because they cannot assess in a holistic way all the environmental impacts arising from the life cycle of the products. Nevertheless, application of Life Cycle Assessment to new developments at the lab scale is not trivial because it requires expertise and data that are not necessarily known by the chemist. Also it is complex to model the impacts of new products at industrial scale. To tackle these issues, we developed a methodology and an associated tool that enable to assess environmental impacts of new chemical products with data that are easily accessible for the chemist at the lab scale. From these data, quantity of inputs, generation of waste, and energy use during the reaction at both the lab and industrial scale are quantified. This is done with a set of assumptions and modelling approaches about the nature of chemicals and energies, the question of recovery and treatment of them by distillation, incineration and waste water treatment adapted for the fine chemical industry. It results in precise life cycle inventory foreground data that can be included in SimaPro software using ecoinvent database for background data to compute life cycle impacts. This procedure has been tested for comparing different catalytic systems for the aldol reaction metal catalyst, organo-catalyst, and enzyme. Input data at the lab scale were collected from the chemistry literature. It shows that for all reactions, solvent production as well as waste treatment (through distillation/incineration or waste water treatment) has an important contribution to impacts. Modelled impacts at the industrial scale are therefore sensitive to the quantity of solvents used and to the fate of the waste and co-products. It is also possible to compare the catalytic reactions at both the lab scale and at the industrial scale considering different assumptions regarding quantity of solvents used, recovery rates by distillation, etc. This study shows that LCA can inform chemists on the greenness of their catalytic systems with quantitative values.

An integrated Life Cycle Assessment and Risk Assessment approach for assessing the environmental sustainability of nanoproducts

B. Salieri, EMPA / Technology and Society Lab; L. Barruetabena, GAIKER-IK4; C. Micheletti, B. Suarez, TEMAS AG; N. Jacobsen, N. Hadrup, NRCWE; A. Sanchez, IOM; B. Liguori, ECAMRICERT; F. Benetti, ECAMIRICERT; V. Chapon, INERIS; I. Llopis, GAIKER-IK4; R. Hischier, EMPA / Technology and Society Lab

In the context of the recently finalized H2020 project, NanoReg^2, a new framework for a more comprehensive assessment of the environmental and human implication for engineered nanomaterials (ENMs) and related nano-enabled products has been developed. The developed framework is based on the integration of Life Cycle Assessment (LCA) and Risk Assessment (RA) methodologies during each stage of the innovation process for ENM products. Following a standard stage model, the framework is structured into four distinct phases: in stage one ("business idea"), the core business idea is described, an initial qualitative scoping of possible potential impacts and risks is established and the main legislative requirements are considered; in stage two ("business concept"), a simplified screening LCA-RA of potential benefits and risks (for workers, consumers and the environment) is performed, allowing a first rough evaluation of the sustainability of the product, based on qualitative/quantitative data from literature; stage three commences as experimental testing starts (stages 3a and 3b-"Prototype ENM/Prototype industrial sector"), and entails the undertaking of an LCA and RA at the lab and industrial scales, providing a first quantitative evaluation of the product; in the fourth and final stage ("validation and market"), REACH, product-related regulations/requirements and labelling requirements are integrated into the assessment. At each stage, different tools (e.g. LICARA, NanoRiskCat, Nanosafer, Swiss precautionary matrix) are used to provide valuable insights into performance to support the company in the process of the evaluation of the risk and sustainability of their product. Thus, our framework serves to help identify and minimise risks at an early stage in the innovation cycle and ensure that safety and sustainability implications are considered from the onset. For emerging products this is of high relevance as it enables risk and product management options to be enacted prior to the nanoproducts entering the market. In this presentation, this stage-based, integrated RA-LCA framework will be presented in more detail and its applicability will be demonstrated through several case studies regarding ENM production and application. In addition to the LCA and RA activities, the feasibility for adding a socio-economic component to this framework will be discussed.

How can process simulation be used to get more reliable data for LCA of mining emerging technologies?

S. Muller, J. Bodin, BRGM; J. Villeneuve, BRGM / Waste and raw material unit

In the context of the Raw material initiative launched by the European Commission in 2008, the European funded project IMP@CT aims at unlocking the access to small complex mineral deposits existing in Europe. To unlock this access, the project's goal is to develop modularized mobile plants (MMP) that can economically operate different type of ores in different types of geological and geographical contexts. More specifically, the project aims at deploying a pilot MMP that contains new technology methods related to mining, mineral beneficiation and waste and water management. The environmental impacts of the developed new technologies is assessed through Life cycle assessment (LCA), notably the potential benefits against business as usual (BAU) solutions. Two challenges arise in this environmental assessment: 1/ the upscaling effect: how can we compare pilot technologies to BAU ones? 2/ contextual assessment of IMP@CT technologies: how can we provide conclusions depending on the geological and geographical contexts? The first challenge is met using mineral process simulation, which is used to predict plant performances based on experimental data. The simulator is built on experimental data using USIM PAC^{TM} and consists in a complete flowsheet design along with a material model definition and several unit operations models adjusted on experimental mass balance. Outputs of the simulator consist, for each unit process of the plant, in flow rates (solids and liquids), consumption of energy and reagents for example. The second challenge of adaptability is met by creating an Excel tool that links the results of the process simulation with additional models, based on expert's judgments and literature data, to complete the whole foreground modelling and with information on the goal and scope that are based on the geological and geographical contexts. This tool's outputs are the foreground modelling of one ton of operated ore using IMP@CT developed technologies. This modeling is translated into ecoinvent 3.4 to be imported and assessed through Simapro 8.5 software. To use mineral processing alongside LCA allows the environmental assessment of emerging technologies to be built on more reliable data notably when upscaling effects arise. The building of the specific tool gives the adaptability to assess different kind of scenarios. At the end, results obtained can be used by decision makers for both eco-design approaches and benchmark assessments.

Wastewater Effluents: How Research Can Improve Risk Assessment and Regulation

386
Targeting bioactive compounds with a combination of specific in vitro screens and high-performance thin-layer chromatography
C.E. Riegraf, German Federal Institute of Hydrology; D. Shakibai, The Hebrew University of Jerusalem; L. Moscovici, The Hebrew University of Jerusalem / Institute of Life Sciences, Department of Plant and Environmental Science; N. Rmailah, The Hebrew University of Jerusalem; H. Hollert, RWTH Aachen University / Institute for Environmental Research; G. Reifferscheid, German Federal Institute of Hydrology; S. Belkin, The Hebrew University of Jerusalem; S. Buchinger, Federal Institute of Hydrology / Department G Biochemistry Ecotoxicology
Micro-pollutants (MPs) exhibiting (eco)toxicological effects pose a well-known threat for environmental and human health, if released into the environment e.g. by wastewater treatment plants (WWTPs). The assessment of wastewater quality based only on indicator compounds does neither provide a reasonable evaluation of possible wastewater-associated adverse effects nor the possible generation of bioactive transformation products (TPs) by the treatment. *In vitro* bioreporters allow the analysis of the biological activity of a sample; however, the detected activity may not be directly linked to the identification of the substances that are responsible for the observed effect. The detection of bioactive compounds within an effect-directed approach (EDA) can be achieved by combining high-performance thin-layer chromatography (HPTLC) with bioreporters, which enable the assessment of the bioactive composition of the sample by a generation of activity profiles even in complex matrices. Furthermore, these activity profiles allow to determine a compound-specific effect-based elimination efficiency of WWTPs and thus the comparative assessment of various treatment technologies. Based on previous findings demonstrating the combination of HPTLC with the yeast estrogen screen (YES), we developed a comparable approach for genotoxicity (recA), androgenicity (YAS), thyroidogenicity (TR), dioxin-like effects (YDS) and effects on the vitamin D receptor (VDR). The already developed setup contains: (i) extraction and enrichment of MPs and possibly their TPs by solid phase extraction from environmental samples, (ii) separation of extracts and model compound mixtures using HPTLC, (iii) adverse effect quantification of the individual separated compounds using genetically engineered yeast (*Saccharomyces cerevisiae*) or bacterial (*E. coli*) bioreporters. The physical removal of separated compounds from the HPTLC plates and their identification using HPLC-MS is currently under development. Within our study we demonstrate the successful performance of the bioassays recA, YAS, TR, YDS and VDR on HPTLC-plates using several model compounds. The applicability of the developed methodology was demonstrated by the analysis of enriched influent and effluent extracts from a WWTP. We anticipate our methodology to substantially broaden the spectrum of specific endpoints combined with HPTLC for a more sophisticated screening of environmental samples such as sediment extracts, surface- and wastewater.

387
The chain approach on pharmaceuticals in the Netherlands: a wicked problem.
C. Moermond, RIVM / Centre for Safety of Substances and Products; M. De Rooy, Ministry of Infrastructure and Water Management
Wastewater Treatment Plant effluent with pharmaceutical residues is discharged into surface waters, which is raising substantial societal concerns. Because of these concerns, the Dutch government, together with many stakeholders from the health and water sectors, has developed a so-called chain approach to reduce the emission of pharmaceuticals to surface waters. This issue meets all the characteristics of a wicked problem, as it is a complex problem that is characterised by scientific uncertainties, multiple stakeholders with different values and interests, institutional complexity and lacks an easy solution. Within this chain approach, source measures as well as end-of-pipe measures are identified and, where feasible and effective, implemented. In this presentation, the development of the chain approach and a number of possible measures are discussed. Some measures are relatively easy to implement, such as as a campaign to reduce the amount of fluid leftovers to be disposed of in the sink. However, many measures seem relatively easy to implement but in practice appear to be a wicked problem in itself. Some examples are discussed, such as collection of X-ray contrast media using urine bags, collection of left-over pharmaceuticals at the pharmacy, source measures to control emissions of cytostatics, identification of pharmaceuticals to replace harmful pharmaceuticals, upgrading sewage treatment plants. The feasibility of these measures and the problems faced when implementing these measures is discussed.

388
Sulfamethoxazole in the Vecht catchment: An application of the GREAT-ER model to assess antibiotic concentrations in whole river catchments
G. Niebaum, University of Osnabruck / Institute of Environmental Systems Research; V. Lämmchen, University of Osnabrueck; J. Klasmeier, University of Osnabrueck / Institute of Environmental Systems Research
Geo-referenced simulation models can support chemical exposure assessment in large river systems. Besides identification of hotspots, such mechanistic models are applied to gain a better understanding of the fate of chemicals in the environment. The geo-referenced exposure assessment tool for European rivers (GREAT-ER) has been designed to predict spatially explicit concentrations of 'down-the-drain'-chemicals in rivers. In this study, the model is used to predict the fate of the antibiotic sulfamethoxazole (SMX) in the catchment of the river Vecht (Germany, Netherlands). SMX has been identified as one of the antibiotics of particular concern in aquatic environments. Predicted environmental concentrations of SMX are of the same order of magnitude as those from monitoring campaigns carried out in European rivers. Sewage treatment plant (STP) Nordhorn is identified as one of the main emission sources of the river Vecht. A scenario in which this STP is theoretically equipped with a tertiary treatment stage showed a decrease of maximum average concentrations by a factor of 3. The probability of exceeding an ecotoxicological PNEC of 0.59 μg/L is relatively low in the Vecht catchment. Furtheremore, the PNEC for resistance selection (16 μg/L) is far above the maximum of simulated SMX concentrations (0.81 μg/L) in the Vecht catchment. Therefore, no actual risk for the aquatic environment is predicted from SMX emissions via household wastewater in the Vecht catchment.

389
Toxicity removal by advanced wastewater treatment: A systematic review of effect-based studies
J. Völker, NTNU University / Biology; M. Stapf, U. Miehe, Kompetenzzentrum Wasser Berlin gGmbH; M. Wagner, Norwegian University of Science and Technology NTNU / Bioanalytical Toxicology Group
The discharge of conventionally treated wastewater represents a major point source of micropollutants. To address this issue, several countries either consider or have already started to upgrade their wastewater treatment plants (WWTPs) with technical solutions such as ozonation or activated carbon treatment. An evaluation of these technologies on a per-chemical basis covers only a small fraction of known micropollutants and may, thus, not represent the actual removal performance. In addition, gaps in knowledge regarding the occurrence of unknown compounds, transformations products, and potential mixture effect exist. To overcome these limitations, effect-based measurements are increasingly integrated into the evaluation of advanced wastewater treatment plants, given that bioassays provide a more comprehensive picture of their performance in removing toxicity rather than single chemicals. However, while several reviews of target micropollutants exist, a systematic review of effect-based measurement data is lacking. Within the framework of a systematic review, we searched Web of Science for studies investigating pilot or full-scale ozonation or activated carbon treatment by effect-based methods. This search returned 2464 studies, from which we removed studies published before 2000, reviews and duplicates. Subsequently, we screened 2101 abstracts and 136 full-texts using pre-defined exclusion criteria resulting in a final set of 45 studies. We extracted the data from 47 *in vitro* bioassays and 17 *in vivo* model organisms and performed a quantitative evaluation of *in vitro* data by calculating removal rates for the different treatment options as well as a qualitative evaluation of *in vivo* data according to the reported adverse effects. Based on this extensive data set, we will give an overview of applied methods, summarize consistent and contradictory results, and highlight identified research gaps. Moreover, to critically assess whether upgrading WWTPs is beneficial, we will discuss the collected data set in the context of recently proposed effect-based trigger values.

Ozonation alters toxicity of pharmaceuticals
J. Pohl, Swedish University of Agricultural Sciences (SLU) / Department of Biomedical Sciences and Veterinary Public Health; L. Ahrens, Swedish

University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; G. Carlsson, Swedish University of Agricultural Sciences / Department of Biomedical Sciences and Veterinary Public Health; O. Golovko, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; L. Norrgren, Swedish University of Agricultural Sciences / Department of Biomedical Sciences and Veterinary Public Health; J. Weiss, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; S. Örn, Swedish University of Agricultural Sciences / Department of Biomedical Sciences and Veterinary Public Health
Pharmaceutical residues are polluting the surface water environments worldwide. Sewage and wastewater treatment therefore needs to be improved in order to remove pharmaceutical residues from the effluent. One such treatment improvement is effluent ozonation. Even though ozonation has proven to be very efficient in reducing pharmaceutical parent compound concentrations in wastewater effluents, much remains unclear regarding potentially toxic ozonation by-product (OBP) formation. In this study we sought to elucidate toxic response of ozonated pharmaceuticals in zebrafish (*Danio rerio*) embryos in a fish embryo toxicity (ZFET) assay. Three pharmaceuticals commonly detected in wastewater effluents were evaluated for embryotoxicity before and after ozonation, i.e. carbamazepine, diclofenac, and oxazepam. Chemical analysis showed that carbamazepine and diclofenac were largely removed by ozone (90±11% and 97±3.8%), whereas oxazepam was removed to a lesser extent (19±5.7%). However, the ZFET assay revealed diverging toxicities. Diclofenac toxicity decreased with increasing ozonation. Oxazepam did not cause toxicity in the ZFET assay either pre- or post ozonation. However, indications of altered larval behavior in 6-day-old larvae were detected in the ozonated oxazepam treatment group. Carbamazepine toxicity on the other hand, increased with increasing ozonation. Chemical analysis showed the formation of two OBPs (carbamazepine-10,11-epoxide and 10,11-dihydrocarbamazepine), potentially explaining the increased toxicity. In conclusion, we have shown that while diclofenac toxicity was effectively removed by ozonation, carbamazepine embryotoxicity increased, possibly via formation of OBPs. The results of this study highlight the importance of new chemical and toxicological knowledge regarding the formation of OBPs in post-ozonated effluents. Work to establish OBP identities and toxicities (individually and in mixture) is ongoing.

Emerging Contaminants in Water Systems: Potential Health Impact of Wastewater Reuse as Management Strategy for Water Security in South Africa

O.S. Fatoki, Cape Peninsula University of Technology / Chemistry; B. Opeolu, Cape Peninsula University of Technology / Faculty of Applied Sciences; B. Genthe, CSIR, Stellenbosch; O.S. Olatunji, University of KwaZulu-Natal, Westville, Durban, South Africa / School of Chemistry and Physics
South Africa as a country is water stressed but the growing effects of climate change with its extreme weather conditions and erratic rainfall pattern is aggravating the situation with incidence of droughts in many parts of South Africa, and Cape Town in particular, which is a major tourist centre in South Africa, the city experienced its major drought recently with attendant water scarcity scenarios in the city with the possibility of "Day zero" has been stated by provincial government when taps may run dry in the city. As a result of the impact of drought, water security will be a concern for many years to come in South Africa with consequents effects in people's health and economic activity in the city. One of the water management strategies being effected by government is promotion of wastewater reuse both domestic and agricultural use. However with the increasing concern on the occurrence of some pollutants of emerging concern in the water and wastewater systems in South Africa like the endocrine disrupting chemicals, there are concerns that these chemicals can pose a health threat to people especially as current technologies being used by many municipalities for water and wastewater treatment are not equipped to remove these chemicals. Many EDCs of are persistent in the environment and have been associated with several disease in humans. Our studies in the Cape Town environment have indicate the presence of such chemicals like BRFs, PFOS and pharmaceutical residues and for instance our health risk bioassay gave indication of slight risk of developing cancer through accidental ingestion via recreational activities . Ames tests result revealed clear mutagenic activities from wastewaters from livestock agricultural farms. High levels oestrogenic activity were also found in some of the wastewaters. If the waters were used for domestic purposes and sufficient treatment are not made, or if the water was used for irrigation purposes, greater risk would be expected. Our study also proposed a wastewater treatment technology using β-FeOOH/NiO nano composite material to remove EDCs from the wastewaters before reuse. *Table 1 could look like this*

Organic Micropollutants in Urban Waters (I)

Temporal trends of pharmaceuticals sorbed to suspended particulate matter of German rivers

L. Boulard, G. Dierkes, German Federal Institute of Hydrology; A. Wick, Federal Institute of Hydrology; T. Ternes, Bundesanstalt für Gewaesserkunde
Several studies constrain a wide distribution of pharmaceuticals in rivers and streams. However, little is known about partitioning of pharmaceuticals between the water phase and suspended particulate matter (SPM). To close this gap of knowledge, we developed and validated a sensitive and high throughput analytical method for the analysis of 56 pharmaceuticals, 45 metabolites and transformation products (TP) as well as the artificial sweetener acesulfame sorbed to SPM. The method was based on pressurized liquid extraction (PLE) followed by a clean-up via solvent exchange and detection via direct injection-RPLC-MS/MS and freeze-drying-HILIC-MS/MS. SPM of annual composite samples were analyzed to determine the pharmaceutical concentrations between 2005 and 2015 at four sites of the river Rhine: Weil, Iffezheim, Koblenz and Bimmen as well as between 2006 and 2015 at one site of the river Saar, at Rehlingen. In these SPM samples, up to 61 of the 102 pharmaceuticals were detected with concentrations ranging up to 189 ng/g for guanyl urea, a transformation product of the antidiabetic metformin. The annual concentrations exhibited for most pharmaceuticals a good correlation with the consumption quantities in Germany. Partition coefficients (Kd) were determined for 91 analytes. They ranged from 0.64 L/kg to 9300 L/kg. For 19 pharmaceuticals Kd values were even found to be above 100 L/kg. Comparison of measured concentrations of pharmaceuticals in water with those measured in SPM showed that experimental partition coefficients can be used to estimate the water concentrations based on SPM concentrations. Benefits and the scope of SPM analysis for environmental monitoring of pharmaceuticals are discussed. Especially the possibility of the analysis of pharmaceuticals having elevated Kd values to calculate corresponding water concentrations is confirmed.

393

Does the use of organic substrates favour the degradation of Emerging Organic Contaminants during artificial recharge of aquifers?

C. Valhondo, Ins of Environ Assessment&Water Resch (IDAEA-CSIC); L. Martínez-Landa, Tecnical University of Catalonia UPC; J. Carrera, IDAEA CSIC; S. Diaz-Cruz, IDAEA-CSIC / Environmental Chemistry
The reuse of impaired waters has become a required component of water resources management due to the increasing demand of quality water, especially in arid and semiarid regions. Therefore, the development of sustainable, high-efficiency, low cost technologies for water treatment is urgent. Managed artificial recharge of aquifers (MAR) through infiltration basins is a low-energy and low-cost water recycling technology which allows to improve the recharge water quality and to increase groundwater resources. Wastewater treatment plant's effluents are very often used as a water source for MAR through infiltration basins. Emerging organic contaminats (EOCs) are not completelly removed during conventional treatments. Therefore, to understand the fate and transport of such contaminants during MAR is essential to select the possible location, to design the MAR system and to avoid aquifer contamination. The objective of this study is to design and test reactive barriers based on organic substrates to prevent leaching of EOCs, pathogens, and nutrients by increasing sorption surfaces and by releasing dissolved organic carbon to the infiltrated water, promoting diverse redox conditions and microbial communities. Six meso-scale system of artificial recharge were built inside a wastewater treatment plant facilities in order to compare the efectiveness of the reactive barriers and the role of diverse experimental conditions. Each one of the six systems (2.5 x 15 m) emulate an aquifer with an infiltration basin. The recharge areas of five systems were complemented with reactive barriers based on organic substrate. The system containing only sand in the recharge areas was stablished as the reference system. The dissolved organic matter (DOM) released by the reactive barrier into the infiltrated water was enough to achieve a broad range of redox conditions. Preliminary results from passive samplers show a better performance of the systems operating with the reactive barrier.

394

Sources and environmental levels of pharmaceuticals in the Baltic Sea region

I. Putna, Latvian Institute of Aqutic Ecology, agency of DU / Experimental Hydrobiology; M. Lehtonen, Finnish Environment Institute SYKE / Laboratory Centre; H. Ek Henning, County Administrative Board of Östergötland / Department of Environmental Protection; L. Äystö, Finnish Environment Institute, SYKE; S. Hoppe, County Administrative Board of Östergötland; I. Barda, Latvian Institute of Aqutic Ecology; K. Siimes, Finnish Environment Institute SYKE / Centre for Sustainable Consumption and Production; R. Kalinowski, Institute of Environmental Protection - National Research Institute / Department of Ecotoxicology; N. Perkola, Finnish Environment Institute, SYKE / Laboratory Centre
The active pharmaceutical ingredients (APIs) have beneficial effects on human and animal health, but their undesired occurrence and effects in the environment is a global concern. The EU Water Framework Directive (WFD) considers the contamination of water with API residues as an emerging environmental concern. Baltic Sea has a large catchment area inhabiting 85 million people. Residues of e.g. hormones, anti-inflammatory and analgesics and antibiotics have been detected in the BS water or fish, but their environmental fate and effects on biota are still poorly known. EU WFD obliges member states to monitor certain APIs which may get legally binding environmental quality standards in surface waters

and emission reduction measures in the near future. HELCOM's status report on pharmaceuticals in the Baltic Sea region (BSR) provides a preliminary assessment that serves as a background for regional environmental policy regarding pharmaceuticals. The overall aim of this study is to fill in data gaps, identified by e.g. HELCOM, in order toget a more complete picture of significant sources and the extent of contamination by pharmaceuticals within the BSR. This information will in turn be used to evaluate environmental risks and to recommend efficient measures to reduce pharmaceuticals entering the Baltic Sea. Sampling has been performed in selected river basin districts of Finland, Estonia, Latvia, Poland, Germany and Sweden. Data collection covered emissions from point sources such as municipal wastewater treatment plants (MWWTPs), manufacturing facilities, hospitals, fish and livestock farms, as well as input of pharmaceuticals via agriculture, aquaculture and landfills Total of 55-75 APIs were analysed from WWTP influents and effluents, surface waters and sea water. Sample analysis is still ongoing, but first results show that that main source of API in the environment is unsufficiently treated WW from WWTP. The highest concentrations of APIs were found representing groups of anti-inflammatory drugs and drugs connected to cardio vascular deseases. API results of surface water showed huge variation of API concentrations between different countries and sampling points. The most environmental risky compounds will be pointed out for further necessary regulatory and emission reduction actions. Research was performed in the framework of EU Interreg BSR project "Clear waters from pharmaceuticals – CWPharma" (R055).

395
Assessment of input of organic micropollutants and microplastics into the Baltic Sea by urban waters
U. Bollmann, Geological Survey of Denmark and Greenland / Environmental Science; J. Vollertsen, Aalborg University / Department of Civil Engineering; M. Simon, Aalborg University; K. Bester, Aarhus University / Environmental Science
Urban waters, i.e., treated and untreated wastewater, treated and untreated stormwater as well as combined sewer overflows, are known emission pathways for micropollutants and microplastics into marine waters. Based on a model city with an exemplary sewer system and measured concentrations in the single sources, the relevance of the different emission pathways were modeled for different micropollutants. Additionally, the urban water catchment of the Baltic Sea and the associated water flows via the different sources were estimated. Subsequently, the emissions of micropollutants from urban areas to the Baltic Sea were assessed. According to our assessment, most micropollutants reach the receiving waters via treated wastewater (e.g., diclofenac). Thus, only for compounds with very high removal rates during conventional wastewater treatment, combined sewer overflows and untreated wastewater (due to misconnections in separated sewer systems or houses not connected to the sewer systems) become the dominating pathways (e.g., the disinfectant triclosan). Additionally, those compounds being present predominantly or solely in urban runoff (e.g., film-preserving biocides like terbutryn), stormwater and combined sewer overflows are the predominant pathways. As both, wastewater and stormwater treatment, are removing microplastics from the water phase to a high extend, untreated wastewater, untreated stormwater and combined sewer overflow are the predominant sources for input of microplastics into the Baltic Sea. Based on the measured concentrations in the different sources and the estimated water flows, the total mass loads of the single compounds entering the Baltic Sea reached up to several tons per year.

396
Identification and removal of hazardous substances in Estonian municipal wastewater treatment plants
V. Kõrgmaa, Estonian Environmental Research Centre / Environmental Chemistry; M. Laht, Estonian Environmental Research Centre / Analytical and Environmental Chemistry; E. Lember, K. Pachel, TalTech / Architecture Civil and Environmental Engineering; M. Kriipsalu, Estonian University of Life Sciences / Institute of Forestry and Rural Engineering; A. Iital, TalTech / Architecture Civil and Environmental Engineering
Identification and removal of hazardous substances in Estonian municipal wastewater treatment plants Chemical pollution poses a threat to the aquatic environment and to the human health. Wastewater treatment plants are the first defensive line between aquatic environment and emissions of pollutants. This study focuses on identification of most relevant priority substances in Estonian municipal wastewater and their removal rate in treatment process. In total, 72 spot samples and 48 composite samples among with 32 sewage sludge samples were collected from influents and effluents of nine MWWTs and analyzed for 282 different substances. Potential sources for hazardous substances were identified using substance flow analysis methodology. Wastewater analysis showed that 143 substances were not found above LOQ. Di-2-ethylhexylphthalate (DEHP), toluene and heavy metals (As, Ba, Ni, Pb, Zn) were found from all samples. For some of the substances seasonal (e.g. diuron, glyphosate, trichloromethane) or population density (e.g. tetrachloroethene was detected only from MWWTPs with capacity more than 10 000 PEs or median concentrations of trichloromethane increased linearly according to the plant size) patterns could be detected. Yearly loadings of hazardous substances into MWWTPs as well as possible emissions to the environment were calculated based on actual measurements and flow rates of selected wastewater treatment plants. Table 1 shows loadings of relevant hazardous substances in Estonian MWWTPs. Substance Influent Effluent Sewage sludge kg/y kg/y kg/y Zinc (Zn) 4 923 1 533 14 888 AMPA 27 48 12 Di-2-ethylhexylphthalate (DEHP) 133 42 302 Glyphosate 16 26 6 Lead (Pb) 406 18 388 Trichloromethane (chloroform) 31 15 4 4-Nonylphenol 5 0 26 Toluene 169 8 27 Anthracene 1,3 0,1 1,5 Diuron 1,5 1,9 0,1 Table 1. Loadings of relevant hazardous substances in Estonian MWWTPs in 2017-2018 (kg/year) This study showed that many substances that are subject to international restrictions (e.g. Stockholm Convention, REACH) are still present in raw sewage and treated effluent. For most of the substances present in influent removal in MWWTPs was observed, but the chemical analyses of sewage sludge indicate that pollutants are often transmitted from water to the biomass.Table 1. Loadings of relevant hazardous substances in Estonian MWWTPs in 2017-2018 (kg/year)

397
Mining the chemical information of urban wastewater - Monitoring human exposure to phosphorous flame retardants and plasticizers (PFRs)
F.M. Been, KWR Watercycle Research Institue; M. Bastiaensen, University of Antwerp / Toxicological Centre Dep of Pharmaceutical Sciences; F.Y. Lai, Swedish University of Agricultural Sciences SLU; A. Van Nuijs, A. Covaci, University of Antwerp / Toxicological Center
Phosphorous flame retardants and plasticizers (PFRs) have been increasingly used in the past years. Because of their ubiquity and the multiple exposure routes, they may pose a threat to human health. At the individual level, exposure to contaminants is generally assessed through the analysis of specific biomarkers in biological matrices. However, these studies are subject to limitations regarding monitoring of exposure in the general population over time and space. In particular, they are expensive, often lack a temporal dimension and suffer from selection bias. In this perspective, wastewater analysis complements human biomonitoring by gathering population-wide information about exposure to contaminants. This work focused on exploring the possibility of monitoring human exposure to PFRs through the analysis of urban wastewater. Solid-phase extraction and liquid chromatography tandem mass spectrometry were used to analyse selected biomarkers. Both spatial and temporal differences in levels of selected biomarkers were investigated by collecting samples in different locations and time periods. Substantial variability could be highlighted from a geographical perspective, suggesting that differences in exposure to PFRs exist among the investigated catchments. Time trends between 2013 and 2016 were investigated for one location and significant patterns could be highlighted. In general, these trends were in line with results from human biomonitoring studies and reports about production volumes. Finally, using stochastic urine production models and Monte Carlo simulations, attempts were made to estimate average urinary concentrations. Obtained concentrations were generally higher compared to results from human biomonitoring surveys. This could be linked to uncertainties in the calculation approach, input from external sources or differences in the sampling period (i.e., wastewater samples are collected over 24h, whilst spot urine samples are used in human studies).

Ecological Impact and Management of Dumped Munition Sites

398
Sediment CWA and explosives hot spots in the Baltic Sea
J. Bełdowski, Instytut Oceanologii PAN / Marine Chemistry and Biochemistry; H. Lignell, VERIFIN University of Helsinki; M. Szubska, G. Siedlewicz, Instytut Oceanologii PAN; S. Popiel, Wojskowa Akademia Techniczna; J. Nawala, Military University of Technology; D. Gordon, M. Szala, Wojskowa Akademia Techniczna; J. Fabisiak, Akademia Marynarki Wojennej; M. Bełdowska, Institute of Oceanografy University of Gdańsk; P. Vanninen, VERIFIN, University of Helsinki / VERIFIN, Department of Chemistrt
Chemical and conventional ammunition dumped in the Baltic Sea and the Skagerrak contain a wide range of hazardous substances. Considering the growing use of the seabed for economic purposes (offshore wind farms, pipelines, cables etc.), the likelihood of disturbing dumped containers with chemical warfare agents, or sunk mines and unexploded ordnance, causing direct emissions to the surrounding environment and risk of human and wildlife exposure, is increasing. Those munitions, while exposed to sea water, corrode and lose containment, leading to leakage and pollution of nearby sediments. Substances contained therein degrade in time, resulting in pollution of sediments with a mixture of parent compounds and their degradation products, which may be a point source of pollution for the ecosystem. Studies of sediments close to chemical and conventional munitions were performed in Bornholm, Gotland and Gdansk Deeps, as well as Kiel Bay. Pollution of sediments with degradation products of chemical warfare agents, explosives, and mercury coming from munition primers is observed within all studied dumpsites. The magnitude of associated concentrations is low, but spreading to larger area (up to 100m radius) was observed. Taking into account large number of munitions in the Baltic Sea bottom, such local sources may have a real impact on the environment.

399

Tissue concentrations of chemical warfare agents and multi-biomarker responses in cod (Gadus morhua) from munition dumpsites in the Baltic Sea

H. Niemikoski, Finnish Institute for Verification of the Chemical Weapons Convention / Department of Chemistry, University of Helsinki; A. Ahvo, Finnish Environment Institute SYKE / Marine Research Centre; K. Straumer, Thünen Institute of Fisheries Ecology; T. Lang, Johann Heinrich von Thünen-Institut; K.K. Lehtonen, Finnish Environment Institute / Marine Research Centre; P. Vanninen, VERIFIN, University of Helsinki / VERIFIN, Department of Chemistrt

The main chemical warfare agent (CWA) dumping sites in the Baltic Sea are located east of Bornholm and southeast of Gotland. Based on official data, approximately 50 000 tonnes of chemical ammunitions were dumped in the Baltic Sea, mainly in the Bornholm Basin. Previous studies have shown that sediment samples collected from Bornholm area are contaminated by (CWAs) as a result of leaking from the dumped containers. These leaking toxic chemicals, e.g. arsenic-containing and mustard-related chemicals are posing a threat to the marine environment. Quantitative analysis of these chemicals and their degradation products are needed to prove the presence of these CWA-related chemicals in marine biota in order to support the risk assessment for possible accumulation of the substances in the food web. In order to study the uptake of arsenic-containing CWAs in fish in a larger scale, 100 cod (Gadus morhua) samples were collected from the Bornholm dumpsite and analysed for CWA-related phenylarsenic compounds. Also methods for the determination of biological responses (early warning biomarkers) and fish health status were applied in order to study their linkages to the chemical concentrations. Additional 100 samples were collected from the Gdansk Deep reference area. Based on chemical analysis, 13% of the analysed cod muscle samples collected from the Bornholm dumpsite contained CWA-related phenylarsenic compounds at parts per billion (ppb, ng/g) concentration levels. Statistically significant differences were found in most of the enzymatic biomarkers between the dumpsite and the reference site. However, biomarker levels measured from the cod containing the CWA-related arsenic compounds did not differ significantly from the other, "clean" specimens collected at the dumping site. Fish health status will further be studied and correlation with chemical and biochemical response will be evaluated.

400

When lead is dangerous in water environment? Factors influencing on lead transfer from spent gunshot to deposits and water.

L.J. Binkowski, Pedagogical University of Cracow / Institute of Biology

Lead fishing sinkers and spent gunshot are the main sources of lead poisoning among waterfowl. They are also suspected to directly pollute water and deposits, but the conditions under which they would have not been determined.I conducted anexperiment aimed at evaluating the impact of lead pellets in microcosms (n=160) built with two deposit types (mud and gravel), three water pH (4, 7 and 9) and two wind levels (wind and windless simulation). Strong differences in Pb transfer (measured with ICP-OES) between deposit types and pH of water were observed. Wind simulation was a significant factor but only in the case of gravel deposits. The strongest lead input to water and deposit occurred in mud microcosms with a water pH of 4. Median pellet loss during experiment did not differ much between deposit types. The experiment revealed that Pb from spent gunshot is only transferred to the environment in specific environmental conditions. This suggestion is crucial for planning the restoration policy.

401

Concentrations of chemical warfare agents and effects on meiofauna in a Skagerrak dump site

F. Lindgren, Chalmers University of Technology; I. Dahllöf, University of Gothenburg / Biological and Environmental Sciences; V. Paka, Russian Academy of Sciences / Shirshov Institute of Oceanology; H. Niemikoski, Finnish Institute for Verification of the Chemical Weapons Convention / Department of Chemistry, University of Helsinki; L. Kotwicki, Instytut Oceanologii PAN; A. Tengberg, Chalmers University of Technology / Mechanics and Maritime Sciences; P. Vanninen, VERIFIN, University of Helsinki / VERIFIN, Department of Chemistrt; I. Hasselöv, Chalmers University of Technology / Mechanics and Maritime Sciences

Large stockpiles of chemical munitions were dumped after the end of WWII in deep-water areas in the Baltic Sea and Skagerrak. Approximately 65 000 ton chemical warfare agents (CWA), where put in obsolete ships that were sunk between 1947-1948. A deep-water area used for dumping was the so-called Måseskär dumpsite in Skagerrak (27x 21 km), where only unconfirmed information exists of if and how much CWAs that was dumped. In a survey 2015 the area was thoroughly investigated in a hydrographic survey, where 28 wrecks were detected. An expedition to the Måseskär dumpsite area was performed between 17thand-22nd of June 2017. It is located approximately 14 nm west of the island of Måseskär, on the Swedish west coast. The depth in the area is between 190-220 m. Five areas were sampled for sediment using a Niemesto corer (Ø 7cm). Two of the areas were in the vicinity of the ship wrecks (0.5-5 km), one site in between to ship wrecks areas, one area north west of the area with the highest concentrations of wrecks (downstream, 24-29 km to the closest wreck) and the last area was a control area south of the dumping area (22-26 km from the closest ship wreck). At each area five sites were sampled, except for the area with highest concentration of wrecks (cluster 4), were 9 sites where sampled. Mustard gas or degradation products of mustard gas were detected in 13 (45%) of the sediment samples. Concentrations in those samples ranged from below limit of detection to 3.4 μg/kg dw (1,4-oxathiane), where the highest concentration were found in the area with highest concentrations of shipwrecks. Average As concentrations differed between 21.6- 8.5 μg/kg (dw) at 0-3 cm, 19.7-9.0 at 4-7 cm, 17.7- 8.1 at 8-10 cm and 19.2-7.4 at 11-15 cm, measured by XRF. Average As concentrations from 0-3 cm depth differed significantly between the sampled areas ($p < 0.001$). All of the sampled areas in the wreck area (C2-C4) had significantly higher concentrations of As compared to the reference area (C1). These areas had similar As concentrations and did not significantly differ from each other. Meiofaunal community composition differed significantly ($p < 0.01$) between the sampled areas. The reference area (C1) differed signficantly from the other sites, mostly due to a higher abundance of nematodes. In this study we confirm that the Måseskär area is a dumping area for chemical warfare agents, as degradation products of Mustard gas and elevated concentrations of As were detected in the sediment.

402

Blue mussels (Mytilus spp.) transplanted at a German munition dumping site in the Baltic Sea for biomonitoring of TNT and degradation products

E. Maser, D. Appel, H. Martin, University Medical School Schleswig-Holstein Campus Kiel / Institute of Toxicology and Pharmacology for Natural Scientists; J. Strehse, Institute of Toxicology and Pharmacology for Natural Scientists / Institute of Toxicology and Pharmacology for Natural Scientists University Medical School Schleswig-Holstein Campus Kiel

Since World War I considerable amounts of warfare materials have been dumped at sea worldwide, but little is known about the fate of the explosive components in the marine environment. Sea dumped munitions are able to contaminate the surroundings because of the release of explosive chemicals due to corrosion and breaching or by detonation after blast-operations. This implies the risk of accumulation of toxic compounds in human and wildlife food chains. With the help of divers, we performed an active biomonitoring study with transplanted blue mussels (Mytilus spp.) in a burdened area (Kolberger Heide, Germany) with explosive compounds near blast craters. Furthermore, we transplanted mussels in vicinity to a mine mound with over 100 moored mines. In order to monitor any differences resulting from changing seasons, three exposure periods for mussels exposed at the mine mound were chosen. In all mussels deployed at the ground next to the bulk of hexanite, we found a body burden with 2-amino-4,6-dinitrotoluene (2-ADNT) of 103.75 ± 12.77 ng/g wet weight and with 4-amino-2,6-dinitrotoluene (4-ADNT) of 131.31 ± 9.53 ng/g wet weight. 2,4,6-trinitrotoluene (TNT) itself has been found in six mussels with an average concentration of 31.04 ± 3.26 ng/g mussel wet weight. In the mussels positioned at one meter above the ground no TNT nor 2-ADNT could be detected, but 4-ADNT was found in all samples with an average concentration of 8.71 ± 2.88 ng/g mussel wet weight. In mussel tissues from the first exposure period (April – July 2016, 106 days) 4-ADNT ranging from 3.37 ± 1.01 to 7.76 ± 6.53 ng/(g mussel wet weight) could be detected in all samples at each mooring position. After the second exposure period (July – December 2016, 146 days) 4-ADNT ranging from 3.04 ± 1.30 to 4.94 ± 1.60 ng/(g mussel wet weight) has been found in 34 out of 36 samples. After the third exposure period (December 2016 – March 2017, 92 days) 4-ADNT levels ranging from 4.26 ± 1.40 to 7.01 ± 2.41 ng/(g mussel wet weight) were detected in mussels from recovered positions. Neither TNT nor 2-ADNT have been found in any sample. With this biomonitoring system, we could show that blue mussels accumulate TNT and its metabolites 2-ADNT and 4-ADNT in their tissues and we unequivocally proved that toxic explosives accumulate in the marine biota resp. in the marine food chain, thereby posing a possible risk to the marine ecosphere and human health.

403

Toxic effects of dissolved TNT on the Baltic mussels (Mytilus spp.): first results from lab exposure studies

M. Brenner, Alfred Wegener Institute / Biosciences; R. Schuster, Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research / Biosciences; J.S. Strehse, Institute of Toxicology and Pharmacology for Natural Scientists, Kiel / University Medical School; A. Ahvo, Finnisk Environment Institute / Marine Research Centre; E. Maser, University Medical School Schleswig-Holstein Campus Kiel / Institute of Toxicology and Pharmacology for Natural Scientists; U. Bickmeyer, Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research / Department of Ecological Chemistry; K.K. Lehtonen, Finnish Environment Institute / Marine Research Centre

During and after the WWs, large amounts of chemical weapons and conventional munitions stored on German territory were dumped in the Baltic Sea by order of the allied forces or German administration. In addition of being a cheap method of disposal, the belief was that the vast amounts of waters in the oceans would neutralize and absorb the dangerous substances. Nowadays, dumped warfare agents are posing a growing concern for the marine environment since dangerous contents are leaking from corroding metal shells and pollute ambient sediments

and water. Both, chemical and conventional warfare agents and their degradation products have been detected in noticeable concentrations in sediments at the major dumping sites in the Baltic Sea. However, the knowledge about dissolved explosives on the health of marine organisms is scars. Even basic toxicity values such as lethal TNT concentrations are missing in literature for most organisms. Therefore, we conducted blue mussel exposure experiments in the lab to assess environmental impact of dissolved TNT. Biomarkers representing different biological functions including e.g. antioxidant defence, biotransformation, lysosomal membrane stability, cellular energy allocation and condition index were investigated. Moreover, tissue concentrations of TNT and its degradation products were analysed and correlated with the biological effects. First results revealed that mussels show clear reactions of avoidance and negative biological effects when they are exposed to dissolved TNT under lab conditions. For example, shell closure, a simple mechanism to avoid any unfavourable conditions, leads to long exposure times under high concentrations of toxic compounds until lethal doses is reached. In contrast, concentrations of dissolved TNT where no negative effects on mussel's health were detectable were comparably low. Thus clearly demonstrating the overall toxicity of TNT for marine organisms.

Statistical Science and Ecotoxicology: Bright Lines and Dark Alley Ways

404

Statistical ecotoxicology: A crisis of confidence, or, why does it hurt when I P (<0.005)?

D. Fox, Environmetrics Australia; R. Smith, Hydrobiology Pty Ltd; W.G. Landis, Western Washington University / Institute of Environmental Toxicology

It has been said that the integration of statistical methods into ecotoxicological practice has occurred more by osmosis than by design. This has resulted in a hybrid discipline we call *statistical ecotoxicology* that has evolved in a serendipitous manner having no mandate, no clear direction, and an unknown trajectory. In our various roles and capacities we have campaigned for a tighter, more transparent and well-articulated coupling of *statistical science* and *ecotoxicology* to ensure practitioners use methods of data collection and analysis that are fit-for-purpose; robust; scientifically credible and, statistically defensible. Given the recent calls to ban the use of Null Hypothesis Significance Testing (NHST) and (separately) to lower the default 0.05 level of significance criterion to 0.005 it is both timely and pertinent to contemplate what the most recent P-value brouhaha means for ecotoxicology. We conclude that it is time that the existence and importance of *statistical ecotoxicology* as a sub-discipline within our society was formally recognised and given a voice to provide guidance, training and leadership on important statistical issues in ecotoxicology. The status quo fosters uncertainty about best (statistical) practice in ecotoxicology and provides no clear mechanism for issuing guidance.

405

Describing exposure-response to meet the requirements of ecological risk assessment

W.G. Landis, Western Washington University / Institute of Environmental Toxicology; R. Smith, Hydrobiology Pty Ltd; D. Fox, Environmetrics Australia

The use of null hypothesis signifcance testing (NHST)is still the dominant method of reporting exposure-response experiments although it has long been discredited. One of the reasons is that the output of an current ecological risk assessment is a series of probability distributions that describe the multiple outcomes of the interactions among of multiple stressors with multiple endpoints often with correspondingly different management goals. In order to accomplish this task an accurate and complete and probabilistic description of the exposure-response relationships and the environmental factors that alter the interaction be available. NHST approaches do not meet these needs. Risk assessment is akin to the approach of S. Wright in determing the causes of the expression of phenotypes (genes and environment) as opposed to the use of hypothesis testing supported by Pearson, Fisher and their disciple[s.]. Significance in a risk assessment is related to but not the same as for a hypothesis test result. Significance in a hypothesis test is used to make a decision regarding whether to accept or not accept that the result is due to a specific hypothesis. In risk assessment and adaptive management, the output is a probability distribution is used to make a decision on the type of management options that are taken to achieve a specific result with an acceptable probability of success. Fundamental to achieving the kind of information necessary to describe the interactions for a risk assesssmsent is the mapping of the exposure-response relationship, especially where there are dramatic changes in the response and when acted upon by factors such as temperature, cofactors, and nutrients.The reporting of NOEC, LOEC and other values derived from the NHST approach are not informative in current risk assessment techniques. Such reporting is not probabilistic and does not reflect the uncertainties in the exposure-response or other types causal interactions. However, significance, as part of a decision-making process does have an important role to play, especially in the evaluation of management options following a risk assessment process. Significance means that the outcome was informative in making a decision regarding the use of a particular managment treatment in the context of the social, economic and engineering priorities.

406

Promoting data literacy to improve statistics in ecotoxicology

R. Wolf, NIVA - Norwegian Institute for Water Research / Section for Ecotoxicology and Risk Assessment; J. Heuschele, University of Oslo / Section for Aquatic Biology and Toxicology; C. Scherer, Goethe University Frankfurt / Section for Aquatic Ecotoxicology; M. Wagner, Norwegian University of Science and Technology NTNU / Bioanalytical Toxicology Group; K. Tollefsen, Norwegian Institute for Water Research NIVA / Section for Ecotoxicology and Risk Assessment

Ecotoxicology statistics are still dominated by comparison approaches, like *t*-test and ANOVA. Often *post-hoc* tests follow, to determine significant differences between arbitrary treatment groups. The toxicity proxies are typically NOECs and LOECs, which today are disputed. The use and interpretation of *P*-values in this context is seen as highly critical. Dose-response modelling provides a different way of analysing data; however, its algorithms do not evaluate the effects of stressors, but optimize *a priori* curve parameters to fit data points. This results in EC_X/LC_X values, but is still not an analysis of stressor effects in the strict sense. More advanced types of data analysis are needed, e.g., using open source statistical software R. But R is still not broadly used within ecotoxicology. This is due to traditional data analysis following "recipes", without the need for developing literacy for data and its handling, including statistics. Consequently, a "inside-the-box" thinking is widely abundant when developing hypotheses, designing experiments, and analysing data. In ecotoxicology, there has been a traditional focus on strong quality standards for laboratory work, such as the GLP framework. Unfortunately, the same thoroughness is not applied to data, and ecotoxicology needs good data practice (GDP) for handling, analysis (including statistics), and reporting of data. This will increase the current standards of documenting and reporting data analysis, and lower the threshold to approach different statistical methods. We propose the development of transparent ways for reporting ecotoxicology data analysis, data handling, and data visualization. R can aid this process, providing frameworks for documenting and reporting code. In this scenario, GDP will increase usefulness of studies, while minimising investment in time and resources. With big data and data science firmly established as buzz words, it is high time to rethink our data and statistics culture, beginning with small data. We need to sensitize, educate, and train both established scientists and new researchers in principles of modern data handling and statistics. This will ready ecotoxicology for the exciting data and statistics developments ahead of us.

407

Recommended procedures for the interpretation of histopathology data from environmental toxicology studies, including a repudiation of the index system approach

J.C. Wolf, EPL, Inc.

Histopathology is a key endpoint for many environmental toxicological bioassays, as it can provide information relevant to hazard identification, risk assessment, the elucidation of disease mechanisms, monitoring of contaminant remediation efforts, and the general health of animal test subjects. Additionally, morphologic tissue changes can serve as critical links between initiating molecular events and apical effects in adverse outcome pathways. Despite the long established use of this venerable endpoint as a research tool, published recommendations concerning the appropriate collection, interpretation, and reporting of histopathology data for hypothesis-based ecotoxicological challenge studies are not widely available. In particular, issues arise when attempts are made to convert descriptive microscopic findings and semi-quantitative ordinal categorizations of lesion severity to quantitative data. Increasingly evident in the literature are papers in which the histopathology data are reduced to numerical index values per organ type and test organism. Although seemingly scientific, this inherently biased approach relies on a variety of unsupported assumptions and statistically invalid mathematical calculations. More importantly, because they promote the recording of numerous unrelated finding types, many of which are incidental to the study outcome, index systems are highly prone to the generation of false positive and false negative results. One very real danger is that inaccurate conclusions resulting from such analyses will be used in characterizations of hazard or risk to establish public policy. This presentation will illustrate the shortcomings of index systems, and then describe an algorithmic, weight-of-evidence approach for the recording, interpretation, and statistical analysis of histopathology data from toxicological studies that utilize fish as test subjects.

408

Analysis of Non-Target Terrestrial Plant Studies

J.W. Green, JohnWGreen-ecostats.com / Data Science and Informatics

Two types of Non-target terrestrial plant (NTTP) studies are required for registration of crop protection chemicals. Unlike many aquatic studies, it is not uncommon to test 8 to 10 treatment groups (application rates) or even as many as 12 to 14, in addition to one or two negative controls, with 4 to 10 replicates per application rate. There are three primary response: shoot height, dry weight and survival. Requirements include NOEC determination and ECx estimation, x=50 in

Europe and x=25 in the US. There has been recent interest in the US of requiring estimation of ECx for much smaller values of x, such as x=10 or even x=5, at least for the growth responses. Issues of both statistical and regulatory importance for the survival response include how to account for (1) background (or control) mortality and (2) replicate variability, including treatment of the overdispersion that is sometimes observed. Issues of importance for the growth responses include how to (1) model hormesis or low-dose stimulation, which is not uncommon, (2) how to assess the quality of ECx estimates for all responses, and (3) to determine what size effects can be estimated reliably from the data resulting from these studies. Another issue is whether the experimental design should be changed, either to improve the quality of the statistical analysis or to reduce the cost of these studies without sacrificing the quality of statistical conclusions. These issues are explored through real data examples and extensive computer modeling. Some common errors are demonstrated that can seriously bias results. Simple, practical recommendations are made to eliminate these errors and improve the quality of results.

409
The hidden cost of not considering experiment-wise error rates in effluent monitoring
R. Smith, Hydrobiology Pty Ltd; D. Fox, Environmetrics Australia; W.G. Landis, Western Washington University / Institute of Environmental Toxicology
In the analysis of ecotoxicological datasets for both multi-species testing and for contaminant monitoring we tend to ignore the overall experiment-wise error rates. This probably results from a combination of the relative youth of our field of science, a determination to find fundamental or simple answers to puzzling and complex issues and a desire to provide conservative assessments that satisfy the perceived requirements of practitioners and regulators. Nonetheless, it does affect the practice of ecotoxicology in real-world situations and influences real world costs of environmental management. In this paper we will examine the general lack of control of experiment-wise Type I error rates in multi-species and multi-sample assessments of toxicity, arguably the most common practical application of ecotoxicology in environmental assessment. It might be argued that the common practice of applying α=0.05 for each test is a conservative trade-off that increases the statistical power to detect toxicity by an increase in the Type I error rate, but actual measurement of statistical power or experiment-wiseType I error rates are rare in ecotoxicology, so the value of this trade off is rarely known. The net result is that environmental management targets are specified that are based on layers of conservatism, and that have overall error rates that could be measured and reported, but generally are not. How much this costs society and operators in terms of compliance with overly-conservative guidelines is, therefore, not known and incalculable. We believe that it is possible to better report and measure these hidden error rates, and that better insight into them may well provide for more cost-effective management. Perhaps more strongly, failure to consider and manage experiment-wise Type I error rates is a disservice to both operators and regulators alike, and is eschewed in other scientific disciplines

Human Health and Environmental Risk Assessment of Chemical Mixtures: Moving Towards the Non-toxic Environment (I)

410
The scientific and regulatory assessment of mixture ecotoxicology: a critical reflection on known knowns, known unknowns and unknown unknowns
T. Backhaus, University of Gothenburg / Department of Biological and Environmental Sciences
Making use of the experiences gained from the regulation of individual chemicals, various tiered approaches for mixture risk assessment have been suggested during the last decade, published by various national and international regulatory authorities, industry organizations and academics. Most often they are based on a combination of whole-mixture testing and component-based approaches, the latter making use of the classical mixture toxicity concepts of Concentration Addition and Independent Action (Response Addition), which are more and more often embedded in modern ecotoxicological approaches such as read-across methods, species-sensitivity distributions (SSDs), high-throughput testing, TKTD models (e.g. Debtox) and adverse outcome pathways (AOPs). This presentation will present a brief overview of how classic and modern approaches are combined for evaluating the ecotoxicology of chemical mixtures. It will then discuss why the science of mixture ecotoxicology is still insufficiently considered in the practice of chemical risk assessment and management. The following issues will be analysed in detail: (1) the adequacy of the empirical database: how much do we actually know about the ecotoxicity of complex, environmentally realistic mixtures? Do the classic mixture concepts provide a sufficiently reliable basis for predictive mixture assessments? Where are the limits of our current understanding? (2) the complexity challenge: how can we simplify the overwhelming complexity of chemical mixtures to make their assessment manageable in practice? (3) bias and uncertainty: how much accuracy and precision can we expect to achieve with modern approaches, how much do we need for taking regulatory decisions? (4) socio-economic and political consequences: what would/could actually happen if mixture assessments would be systematically implemented on a broad scale? In the end, I argue that the mixture issue is an almost classical example of the "tragedy of the commons", a situation that is simply outside the framework of current (actor-oriented) chemical legislation. Its systematic consideration might need to start with a hard look at the fundamental assumptions that underpin our current frameworks for chemical assessment and management. This presentation is specifically intended as a critical reflection on the state of the art and a discussion starter on the ways forward. The author welcomes any and all feedback.

411
Development of a Multi-Substance Potentially Affected Fraction Method for Assessing the Joint Toxicity of Twenty-two Pesticides with Ten Modes of Action
M.S. Warne, The University of Queensland / School of Earth and Environmental Sciences; C. Neelamraju, R.A. Smith, J. Strauss, R. Mann, R.D. Turner, Queensland Government / Department of Environment and Science
The health and resilience of the Great Barrier Reef (GBR), the world's largest reef ecosystem, is in decline. To improve this situation the Australian and Queensland governments developed the Reef 2050 Long-Term Sustainability Plan (2050 Reef Plan) and the Reef 2050 Water Quality Improvement Plan (WQIP). This WQIP has land and catchment management targets and water quality targets. The latter focus on reducing the annual loads (mass) of fine solids and dissolved inorganic nitrogen and the toxicity of mixtures of pesticides. Specifically, the target for pesticides is for at least 99% of aquatic species to be protected from the combined effects of pesticides at the mouth of waterways that discharge to the GBR. This level of protection is consistent with that recommended to waters in national parks and marine reserves by the Australian and New Zealand Guidelines for Fresh and Marine Water Quality. The multi-substance potentially affected fraction (ms-PAF) method was selected to monitor progress to the pesticide reduction target. This method was selected as it expresses the combined effect of pesticides in terms of the percent of species that would theoretically be affected, which is consistent with the Australian and New Zealand water quality guidelines. The pesticides included in the ms-PAF method were selected because they have been analysed for and are frequently detected in waterways that discharge to the GBR, and they have water quality guideline values (GVs). The 22 selected pesticides included: 2,4-D, ametryn, atrazine, diuron, chlorpyrifos, fipronil, fluoroxypyr, haloxyfop, hexazinone, imazapic, imidacloprid, isoxaflutole, MCPA, metolachlor, metribuzin, metsulfuron-methyl, pendimethalin, prometryn, simazine, tebuthiuron, terbuthylazine and triclopyr. Species sensitivity distributions were derived for each pesticide using fresh and marine species. The groupings of pesticides for msPAF was determined by a combination of literature determinations of the MoA, tests for parallelism of the SSDs, and goodness of fit of each pesticide to global SSDs for various combinations of the pesticides. The toxic effects of pesticides with parallel SSDs (within the same MoA) were estimated using the concentration addition model, while the toxic effects of pesticides with non-parallel SSDs were combined using the response addition model. The ms-PAF method will be used to estimate the combined toxicity of the 22 pesticides to thirty-seven sites during 2017 – 2018.

412
Impactful mixture exposures in Europe's surface waters and prioritizations towards a non-toxic environment
L. Posthuma, RIVM / Centre for Sustainability, Environment and Health; S. Birk, University of Duisburg-Essen / Aquatic Ecology; J. Lemm, University of Duesburg-Essen; D. De Zwart, Association of Retired Environmental Scientists ARES / Centre for Sustainability Environment and Health; D. van de Meent, Radboud University / Department of Environmental Science; J. Slootweg, M. Zijp, RIVM / DMG; A. Focks, Wageningen Environmental Research / Environmental Risk Assessment Team; J. van Gils, DELTARES
Based on analyses of mixture data in the EU-projects SOLUTIONS and MARS we can conclude that the non-toxic environment has not been materialized for a large fraction of European surface waters. To reach this conclusion, we collated data on chemical production, emissions, concentrations and expected impacts, and on ecological status. SOLUTIONS – a project considering the European use and impacts of chemicals in the context of the concepts of Good Chemical Status – provided the former data, and MARS – a project considering the ecological status of European water bodies in the context of multiple stressor impacts – provided the latter. Based on Europe-wide modelling, the analyses of the SOLUTIONS data suggests that mixture exposures exceed the threshold that could be used to define the non-toxic environmental. By aligning the predicted impact data to ecological status data based on monitoring, it was found that indeed mixtures are one of the factors likely shaping ecological communities. That is, higher mixture toxic pressures impose a limitation to maintaining or reaching good ecological status. The findings are discussed in view of further validation data, monitoring and classification methods of the Water Framework Directive, and especially prioritization of management to forward the non-toxic environment.

413

Antibiotics and their mixtures in aquatic and terrestrial ecosystems: do we underestimate risks to environmental organisms?

D. Gildemeister, Umweltbundesamt / German Environment Agency / IV2.2 Pharmceuticals; S. Konradi, Federal Environment Agency (Umweltbundesamt) / Section IV 2.2 Pharmaceuticals; A. Hein, Federal Environment Agency (UBA) / Section IV 2.2 - Pharmaceuticals; U. Kuehnen, Federal Environment Agency

The increasing occurrence of antibiotics in the environment is highly discussed nowadays. Antibiotics used in human medicines are continuously released into surface waters via waste water treatment plants (WWTP), because of incomplete removal, but may also enter agricultural lands via sewage sludge. Antibiotics used in veterinary medicines enter the terrestrial environment via manure and may be transferred to surface waters. Furthermore, antibiotics reach groundwater ecosystems per bank filtration and transport through soil. Environmental risks are considered in the environmental risk assessments of human (HMP) and veterinary medicinal products (VMP) within the authorisation of new medicinal products in the EU. In these procedures the risk of each active substance is assessed for itself. However, environmental organisms may be exposed to several antibiotic substances with a similar mode of action in environmental media like surface water and soil. The intention of the presentation is to show that there are risks to ecosystems arising from the antibiotic substances itself and from their mixtures in addition to the risk of formation of resistant microorganisms. Risks of antibiotic mixtures in the terrestrial and aquatic environment are evaluated by using data of authorisation procedures and from research projects funded by the German Environment Agency (UBA). Recently, risks for plants were identified in authorisation procedures of some VMPs. Many antibiotics e. g. tetracycline, tiamulin, tylosin, trimethoprim are persistent in the terrestrial environment. So, the probability of accumulation in soil and hence the formation of mixtures of different antibiotic substances in soil is high. Furthermore, the most sensitive organisms were identified for the risk assessment from tests of the different taxonomic groups in surface water. Results from an UBA research project demonstrate that antibiotic mixtures have a high relevance in the aquatic environment. The provided overview shows that environmental ecosystems are exposed to mixtures of antibiotics and effects on specific organisms are probable in all environmental compartments. As the implementation of risk mitigation measures is limited, measures to reduce the usage of antibiotics and to improve cleaning technologies are very appreciated by the agency.

414
Spatial aspects of the Baltic fish dioxin risk formation: Social-ecological system analysis

L. Ronkainen, University of Helsinki; J. Tuomisto, National Institute for Health and Welfare; P. Haapasaari, A. Lehikoinen, University of Helsinki

Dioxins have been a nuisance to the Baltic Sea ecosystem for a couple of decades, and even though the concentrations in the environment and biota have decreased, they pose a multilevel social-ecological risk. Dioxins accumulate to fatty tissue, and hence enrich in the food chain ending up to humans who consume fish. We analyzed the dioxin risk in the Baltic Sea using social-ecological system (SES) approach to assess the management of the dioxin issue in spatial terms. We studied the dioxin flux in the Baltic Sea food webs focusing especially on Baltic herring and salmon which are important commercial species and have prominent role in food web dynamics. A systematic literature search was conducted to explore how different elements in indicators of 1) anthropogenic dioxin pollution, 2) ambient environmental conditions, 3) food webs, 4) dioxin concentrations in fish, and 5) human exposure from fish affect the Baltic Sea SES. From 47 articles, reports, and theses, highly heterogeneous data, varying from *In situ* monitoring data to experimental and modelled information, was extracted to create a total of 21 elements to describe the Baltic Sea condition. Arising from the areal differences in dioxin pollution and environmental conditions affecting the ecology and biology, these elements vary spatially, affecting how the final risk is formed in different basins. In the Northern Baltic, Gulf of Bothnia, where dioxin concentrations in herring are the highest, the exposure to a key risk group, women in fertile age, is lower than in the Baltic Proper. On the contrary, salmon PCDD/F concentration is the highest in the Gulf of Finland, while the exposure to the risk group is the highest in the Gulf of Bothnia. This study highlights the importance of integrative SES when evaluating the need for area-specific risk management strategies.

The Environment as a Reactor Determining Fate and Toxicity of Nanomaterials (III)

416
The Influence Of Soil Properties On The Uptake Of Different Ag Nanoparticle Forms By Wheat.

A. Green Etxabe, CEH Wallingford; A. Robinson, Centre for Ecology & Hydrology; R.A. Verweij, Vrije Universiteit Amsterdam / Department of Ecological Science; C.L. Schultz, Centre for Ecology and Hydrology; R. Sekine, Griffith University; C. van Gestel, Vrije Universiteit Amsterdam / Ecological Science; M. Matzke, Centre for Ecology & Hydrology (NERC) / Molecular Ecotoxicology; D. Spurgeon, Centre for Ecology & Hydrology; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology; E. Lahive, Centre for Ecology & Hydrology (NERC)

Silver nanoparticle (Ag NP) addition to terrestrial environments occur through releases from anthropogenic activities. It is expected that most particles will no longer be in their pristine forms when they reach the soil but will have been transformed by their environment (e.g. sulphidisation during waste water treatment). The extent of aging of the Ag NP forms once they are in the soil is influenced by the properties of the soil, and will greatly vary the form of Ag NP to which soil organisms are exposed and the ultimate availability of the silver. The bioavailability of silver forms in amended soils is a key aspect to understanding the environmental risks associated with them. In order to develop models that support site-specific risk assessments we need a better understanding of how Ag NP transformation processes, fate and bioavailability are influenced by soil properties. The aim of this study is to investigate the uptake of silver by wheat *Triticum aestivum,* when exposed to three Ag forms (20nm Ag NP, 27nm Ag_2S NP and $AgNO_3$) in three natural soils with varying pH (4.7-6.5) and organic matter content (0.6-9.6%). Soils were spiked at 10mg Ag/kg and equilibrated for 7 days before seed planting. Exposures were conducted in triplicate and sampled at 1, 4, 6, 13 and 27 days post-emergence (PM). Soils were maintained at 60% water holding capacity and exposures conducted at 20 C with a 16L: 8D photoperiod. Soil pore water was extracted at 6 and 27 days PM (0.45μm and 10 kDa filtered) as a measure of Ag bioavailability in the soils. Roots washed in dH_2O were dried at 70 C and plant growth rates calculated on dry weights.Total silver concentration in the roots, shoots, soils and pore waters were measured by flame and graphite furnace AAS. This study not only shows that different Ag forms are differentially bioavailable to wheat in soil exposures but also that soil properties have a pronounced influence on their bioavailability. This study shows that environmentally relevant forms of Ag NPs (Ag2S) are bioavailable to wheat in soil exposures and that in the Woburn soil the root concentrations of silver from the Ag_2S NP exposure were even higher than those found for the pristine Ag NP or ionic Ag exposures in either Lufa or North Wales. The differences in root silver concentrations between soils seen in this experiment highlight the importance of understanding the environment in which Ag NPs are applied to predict the bioavailability of silver to soil organisms.

417
Ecotoxicology of silver species brought by sewage sludge in terrestrial environment

P. Courtois, LGCgE, Universite de Lille 1

The rise of nanotechnologies in the 90s led to a larger use of silver nanoparticles (AgNPs) in many products, mainly due to their antimicrobial properties. Consequently, a discharge of silver (Ag) into wastewater leading to an accumulation of silver species in sewage sludge has been observed. In this context, a primary source of Ag contamination of terrestrial environments is related to sewage sludge land application for agricultural or remediation purposes. In terrestrial ecosystems, exposure to AgNPs (or Ag species contained in sludge) may change microbial biomass and diversity, decrease plant growth and inhibit soil fauna reproduction. Physiological, biochemical and molecular effects have been evidenced in various soil organisms and microorganisms. AgNPs undergo speciation before spreading on agricultural parcels. The effects of the dominant form in sewage sludge, Ag sulfide, are still too little studied. An experiment have been conducted to evaluate the impact of Ag species on soil microflora and on a macroinvertebrate. Objective was to assess the toxicity of Ag brought into the environment via sewage sludge spreading. The exposure was as realistic as possible. Briefly, earthworms were exposed to mixtures of natural soil and fermented sludge contaminated with Ag (contamination before anaerobic fermentation). Life traits and bioaccumulation of metals have been evaluated for earthworms, diversity and activities were evaluated for microorganisms. First results confirmed that the totality of AgNPs added in microcosms were transformed in sludge. These Ag forms impacted moderately the earthworm test species *Eisenia fetida*. Life traits were not affected by Ag although Ag accumulated in their organism. Gene expression levels of *lysenin*, *superoxide dismutase* and *Cd metallothionein* genes (involved in defense mechanisms against metals) were not affected by Ag in these conditions. The study of soil microorganisms shows that respiration, denitrification and nitrification were not affected by added of sludge contaminated by AgNPs. However, silver had a significant effect on the diversity of communities. Our experiment suggest that although Ag contaminated sludge does not appear to be extremely toxic to earthworms, Ag forms accumulated in animals are thus introduced in trophic chain. Also, the alteration of the diversity of soil microflora could affect long term soil fertility since communities of soil microorganisms are essential for soil fertility.

Time-resolved leaching of engineered nanoparticles from sewage sludge ash

J.J. Wielinski, ETH Zürich/Eawag / Process Engineering; A. Gogos, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Process Engineering, Particle Lab; A. Voegelin, Eawag Swiss federal Institute of Aquatic Science and Technology; E. Morgenroth, R. Kaegi, Eawag - Swiss federal Institute of Aquatic Science and Technology / Process Engineering
Engineered nanoparticles (NP) are efficiently retained in wastewater treatment plants (WWTP) and accumulate in the sewage sludge. The application of sewage sludge as fertilizer in agriculture becomes increasingly difficult due to more stringent environmental regulations. Therefore, increasing shares of sewage sludge are incinerated, preferably in mono-combustion incinerators. To assess the potential release of NP from produced sewage sludge ash, we spiked Au, Ag and CeO_2-NP, representing NP of different reactivity, to a pilot WWTP consisting of conventional activated sludge treatment and anaerobic digestion. Digested sludge was collected, dewatered, dried and incinerated in a pilot fluidized bed reactor. Fly ash was packed into liquid chromatography glass columns and leached using a 53 mM NaCl solution. Individual fractions of the leachate were collected over time. Initial results showed that of the total mass of Au, Ag and Ce in the column, 3.3%, 0.1% and 0.003% was eluted during the experiment, respectively. Al and Fe release was assumed to represent colloid leaching from the ash. The concentration decrease of Au in the leachates followed a first order release and Au concentrations were not correlated with the leaching of Al and Fe. Ag release seemed to partially depend on the Al and Fe release. Ce release only occurred during intense Al and Fe release. Based on the target element release being positively correlated or independent of Al and Fe release, we assumed that Au was only loosely attached to ash matrix. Ag and Ce were partially and mostly incorporated into the ash matrix. Based on these initial results, we conclude that the type of chemical transformation affects the interaction between the NP and the sludge / ash matrix. These interactions seem to dominate the release of NP from sewage sludge ash. NP which are not expected to undergo major chemical transformation during sludge incineration (e.g., AuNP) will only be loosely attached to the ash matrix and thus easily elute. NP that undergo significant transformation and interact with the matrix during incineration (e.g. Ag or CeO_2-NP) will be retained in the ash to a larger extent.

419

Transformation of cerium dioxide nanoparticles during sewage sludge incineration

A. Gogos, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Process Engineering, Particle Lab; J.J. Wielinski, ETH Zürich/Eawag / Process Engineering; A. Voegelin, Eawag Swiss federal Institute of Aquatic Science and Technology; R. Kaegi, Eawag - Swiss federal Institute of Aquatic Science and Technology / Process Engineering
Wastewater treatment plants (WWTP) show high removal efficiencies for (engineered) nanomaterials, resulting in their accumulation in sewage sludge. An increasing percentage of the sewage sludge is incinerated in many countries, including Germany (~30%) and Switzerland (~70%). Given the predicted increase of cerium dioxide nanoparticle (CeO_2 NP) production and the related release into WWTP as well as the growing importance of sewage sludge incineration, knowledge on the physical-chemical transformations of CeO_2 NP during wastewater treatment and sludge incineration is required for a detailed understanding the fate of CeO_2 NP and assessing the (eco-) toxicological effects related to their increased use. Previous studies indicated that the complexity of the experimental system (e.g. type of incineration, matrix in which the CeO_2 NP are dispersed) influences the chemical speciation of Ce in the ashes. We therefore incinerated municipal sewage sludge spiked with CeO_2 of different particle sizes (4 nm ($nCeO_2$), 26 nm ($mCeO_2$) and >16 μm ($bCeO_2$)) in a pilot fluidized bed reactor (FBR) to investigate the transformation of CeO_2 under conditions mimicking full-scale incineration facilities. We used Ce K- and L_3-edge X-ray absorption spectroscopy (XAS) complemented by analytical electron microscopy to assess the speciation of Ce and to characterize the morphology of the Ce-(nano)particles. After one week of incubation in digested sludge under anaerobic condition, $nCeO_2$ already showed partial reduction to a Ce(III)-phase (~40%). Cerium dioxide of larger particle size (m- and $bCeO_2$) was less reactive and did not show any detectable reduction within the same reaction time. In general, incineration of the sludge lead to a further reduction of Ce, which was not observed in previous studies, where pure $nCeO_2$ was incinerated in a muffle oven. Reduction during incineration was nearly quantitative for $nCeO_2$ and much less pronounced for the m-and $bCeO_2$. Ce(IV) in larger (primary-) particle sizes thus was more resistant to Ce reduction during incubation and incineration. In addition, Ce-containing particles in the $nCeO_2$ fly ash showed different morphology and size compared to the original material. We therefore propose that engineered properties of nanocrystalline CeO_2 are likely lost after incineration. Our results also highlight the importance of particle size and the surrounding matrix for the transformation of CeO_2 during sewage sludge incineration.

420

Long term approaches to determine the fate of ceriumdioxid nanomaterial in soil

M. Hoppe, German Federal Institute for Geosciences and Natural Resources / Groundwater and Soil; K. Schlich, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; D. Rückamp, German Federal Institute for Geosciences and Natural Resources; J.J. Wielinski, ETH Zürich/Eawag / Process Engineering; R. Kaegi, Eawag - Swiss federal Institute of Aquatic Science and Technology / Process Engineering; K. Hund-Rinke, Fraunhofer IME / Ecotoxicology
The increasing use of engineered nanomaterials (NM) leads to their release into the environment. There is a special focus on ceriumdioxid nanomaterials (CeO_2 NM) because of their widespread applications (diesel fuel additive, electronic and optical devices, metallurgy, polishing agents for glass and silicon wafers, exterior paints). Atmospheric deposition and sewage sludge applications have been discussed as source for the environmental release of CeO_2 NM. Sludge amendments will result in a CeO_2 NM input into arable soils, which are supposed to be a sink for NM. Here, we summarize the results about the fate and bioavailability of CeO_2 NM from a long term outdoor lysimeter study. The outdoor lysimeter study was performed with CeO_2 NM (CeO_2 NM-212, OECD Sponsorship Programme) which was applied to the lysimeter soil (Refesol 01A, slightly loamy Cambisol, OECD standard 216/217) by sewage sludge or artificial rainwater. After the application, the upper 20 cm of the lysimeters were dug up to receive comparable conditions between the different approaches. The set concentrations of CeO_2 NM after sludge application were 0 mg kg^{-1} (control), 10 mg kg^{-1} and 50 mg kg^{-1} as well as 0 mg kg^{-1} (control) and 10 mg kg^{-1} after rainwater application. The Ce concentrations of percolating water as well as the digested plant materials and soil samples were measured by ICP-OES or ICP-MS. To retrieve information regarding the Ce speciation in the lysimeter, two soil samples were investigated with synchrotron based X-ray absorption near edge spectroscopy (XANES). For both approaches (sludge and rainwater application), no vertical Ce translocation was detected over two years. The Ce concentrations in the percolating water showed no differences in Ce release between the CeO_2 NM spiked lysimeters and the unspiked controls. However, the low Ce uptake to the plant roots increasing from canola to barely suggests that despite the large CeO_2 NM retention, the NM are somehow bioavailable in the rhizosphere. The XANES results showed that Ce^{4+} was partly reduced to Ce^{3+} during the two years of CeO_2 NM aging in the lysimeter soil (50 mg kg^{-1} approach). In general, the results imply that the tested soil is a large sink for CeO_2 NM. However, information regarding the translocation and speciation of CeO_2 NM in crops are still incomplete. Hence, further investigations under realistic exposure scenarios regarding the Ce speciation at the root soil interface are required.

Colloidal stability and bioactivity of Fe3O4 nanoparticles functionalized with humics and silica

T. Kuznetsova, National University of Science and Technology MISIS; L. Bondarenko, Moscow Aviation Institute; P. Uchanov, Institute of Ecology and Evolution RAS / Laboratory for soil ecological functions; A. Sybachin, Lomonosov Moscow State University; V. Terekhova, Lomonosov Moscow State University / Lab of Ecotoxicological Soil Analysis; K. Kydralieva, Moscow Aviation Institute
Investigations of Fe_3O_4 nanoparticles (NPs) functionalized by different inorganic and organic ligands are being increasingly reported in the literature due to the importance for biomedical and ecological applications. The huge diversity of polymers allows for different types of Fe_3O_4 NPs surface functionalization, i.e., introduces charges on the system that can prevent the aggregation of the particles in liquids and improve their chemical stability through surface charge control. In addition to studying the size, structure and composition of the colloidal particles, control of their colloidal stability is very important. Controlling the stability of the magnetic fluids against aggregation is important because the formation of aggregates alters their specific surface area and dispersibility as well as their bioactivity. In the present work, the influence of humic acids (HA) and/or silanes (tetraethoxysilane, TEOS and 3-amino propyl-triethoxysilane, APTES) was studied and correlated with the colloidal stability and bioactivity. The control of the functionalization nature and density (number of layers) on the Fe_3O_4 surface was investigated, electrokinetic measurements (zeta-potential and hydrodynamic diameter), bioactivity analysis were performed. The higher plant − whitemustard *Sinapis alba* L., green algae *Scenedesmus quadricauda* (Turb.) Brev., and infusorians *P?ramecium caudatum* were used as test organisms for bioactivity evaluation. The results suggest that surface charge and bioactivity can be controlled by grafting Fe_3O_4 NPs with HA and/or silanes. The sequential layer-by-layer grafting of precursors onto the NPs surface demonstrated an logical increase in the hydrodynamic diameter (measured by dynamic light scattering) in the row: Fe_3O_4/TEOS< Fe_3O_4/TEOS/APTES< Fe_3O_4/TEOS/APTES/HA. Zeta potential for silica grafted NPs varied considerably with layering from -20 mV (Fe_3O_4/TEOS) to -0.6 mV (Fe_3O_4/TEOS/APTES), which correlates with surface charge provided by the surface amino group of APTES. For the Fe_3O_4 coated by HA zeta-potential increased from 15 mV (bare Fe_3O_4) to -40 mV (Fe_3O_4/HA). The bioactivity of bare and functionalized NPs by silica and/or HA with respect to test-organisms demonstrated higher toxicity for multilayered nanoparticles as Fe_3O_4/TEOS/APTES/HA in compare with Fe_3O_4/HA. *Acknowledgement.* This research has been financed by the Russian Foundation for Basic Research (*#18-33-01270/18)* and the Russian Science Foundation (#16-14-00167).

Advances in Soil Ecotoxicology and Risk Assessment - Impact, Ecotoxicity Tests, and Concepts for a Retrospective Environmental Risk Assessment (III)

422
Potential impacts of plant protection products on earthworms, carabid beetles and vertebrates on agricultural fields
T. Schmidt, IES Ltd / Ecotoxicology; S. Kimmel, Innovative Environmental Services (IES) Ltd. / Ecotoxicology; S. Hoeger, Innovative Environmental Services IES Ltd / Environmental Toxicology; Z. Drmic, M. Cacija, D. Lemic, R. Bazok, University of Zagreb Faculty of Agriculture / Department of Agricultural Zoology; H. Viric Gasparic, University of Zagreb Faculty of Agriculture / Department for Agricultural Zoology
The productivity and sustainability of agricultural fields depend on the maintenance of relevant ecosystem functions as well as on the existence of a sufficiently complex species diversity. In this context, earthworms play a prominent role for soil ecosystem by influencing organic and inorganic matter breakdown, whereas carabid beetles are one of the most important arthropod predators on soil surface. So far, the environmental risk assessment of potential impacts of plant protection products on earthworms (EFSA 2017) and ground beetles (EFSA 2015) is based on single compounds and does not take into account that organisms within and above the soil are exposed to a mixture of active ingredients from different plant protection products within one season and partly over successive seasons. In addition, the potential for secondary poisoning, as assessed in EFSA (2009), may increase if contaminated earthworms and carabid beetles are combined in the diet of a mixed-diet feeding bird or mammal. In a monitoring project, earthworms and carabid beetles were sampled at two seasons from eight fields in Croatia and analysed for up to 300 active ingredients, but no soil concentrations were determined. Based on publicly available draft assessment reports from EC and EFSA, degradation parameters (DT_{50}, DT_{90}) were used to calculate degradation curves and the current soil concentration at the date of earthworm sampling as well as the current residue concentration on soil surface at the date of carabid sampling. Subsequently, bioaccumulation factors were calculated by dividing the analysed pesticide residues in earthworms and carabid beetles by the calculated concentrations in soil and on soil, respectively. The aim of this survey was to check the applicability and reliability of this method and to examine (i) whether a potential of secondary poisoning is needed to be addressed when a bird or mammal feeds both on contaminated earthworms and carabid beetles, (ii) whether the re-calculated soil concentrations of individual active ingredients and mixtures of active ingredients with the same mode of action do pose a potential risk to earthworms and carabid beetles.

423
Improving risk assessment of contaminants in material spread to land
E. Stutt, WCA Environment Limited; I.A. Wilson, G. Merrington, wca; I. Martin, Environment Agency / Analysis and Evaluation Group
Recovery of organic materials to land is an important source of nutrients and organic matter and also a means of minimising waste in a circular economy. However, the presence of chemicals in the recycled materials including pharmaceuticals, veterinary medicines, personal care products and industrial chemicals are becoming an increasing concern in terms of the risks to soil health, wildlife and consumers. Previous assessments of land-spreading have generally had significant deficiencies as they have had to rely on the use of exposures concentrations from the literature, often from different geographical locations, that may have little relevance to the area for which an assessment is taking place. Furthermore, the data may not relate to the particular form of material in which it is applied to land. It is therefore important to obtain data on contaminant levels in the relevant materials in order to perform accurate exposure assessment. Sound risk assessment for environmental and human health is also reliant upon robust evidence on the adverse effects of contaminants. This is often an area of weakness for terrestrial risk assessment as there is an absence of reliable (eco)toxicity data for many of the substances. A study of landspreading was undertaken on behalf of the Scottish Environment Agency (SEPA) and the Environment Agency that involved the sampling and analysis of Scottish biosolids, compost and various animal manures from England and Scotland, all in the specific form in which they are applied to land. Most contaminants were found to occur at lower concentrations than previously reported in the literature, although the synthetic musk HHCB (galaxolide) was measured at elevated concentrations in biosolids; the assessment for long term application to land indicates a potential risk to soil organisms from this substance with RCRs >1. The medicine, ciprofloxacin was identified as posing a potential risk to soil from biosolids application and RCRs>1 were calculated for contaminants in other organic materials. However, some of these conclusions need to be treated with caution as there is considerable uncertainty with many PNECs. Overall, this project indicated a limited potential for risks from organic contaminants in organic materials applied to agricultural soil but it is recommended that there needs to be a broad initiative to compile or generate the necessary data to derive robust terrestrial PNECs that are applicable across Europe and further afield.

424
Scenario Development for Off-field Soil Exposure and Risk Assessment
G. Ernst, Bayer Ag / Ecotoxicology; J. Kleinmann, WSC Scientific GmbH; M. Wang, WSC Scientific GmbH / Dept Efate Modelling; K. Hammel, Bayer AG, Crop Science Division / Environmental Safety; T. Preuss, Bayer Ag / Environmental Safety; P. Neumann, Bayer Ag; S. Bub, Tier3 Solutions; T. Schad, Bayer AG Crop Science Division / Environmental Modelling
In its Scientific Opinion on risk assessment for in-soil organisms EFSA proposes to introduce an off-field risk assessment as soil organisms are potentially exposed to plant protection products outside the treated fields. EFSA proposes a preliminary approach for off-field soil exposure by adding up entries from the different major exposure routes (i.e. runoff, erosion, and drift depositions). EFSA indicates the worst-case character of its scenario "*In the absence of appropriate off-field exposure scenarios…*", and hence, emphasises the necessity for model and scenario development. The present work undertakes first steps (i) to develop a model approach for off-field soil exposure due to runoff, erosion, and drift, (ii) to develop exemplary schematic and real-world scenarios, (iii) which allow to gain insights in off-field soil exposure and risk using case studies. The developments are based on the Specific Protection Goals options discussed by EFSA. Results are intended to support the design of off-field soil exposure and risk characterisation scenarios in a tiered risk assessment scheme and the development of assessment endpoints (e.g. spatiotemporal percentiles of off-field exposure and risk) relevant to address SPGs, with particular focus on the identification of mitigating options (e.g. drift mitigation, vegetated filter strips, in-crop no-spray buffer). Following the developed exposure approach the off-field risk to soil organisms distributed in space and time will be presented depending on substance properties and risk mitigation options and discussed in context of possible future risk assessment framework for soil organisms. The approach is also suitabel for directly linking spatio-temporal explicit exposure with effect modelling (toxicological, population, community) for future risk assessment approaches.

425
Mind the gap - On the way to a spatial and temporal explicit TKTD model for earthworms
V. Roeben, Research Institute gaiac / gaiac- Research Institute for Ecosystem Analysis und Assessment; S. Oberdoerster, Bayer Ag / Crop Science - Terrestrial Invertebrates; K. Rakel, Research Institute gaiac / gaiac- Research Institute for Ecosystem Analysis und Assessment; Y. Capowiez, INRA Institut National de la Recherche Agronomique / EMMAH; T. Preuss, Bayer Ag / Environmental Safety; A. Gergs, Bayer AG - Crop Science Division / Department of Environmental, Social and Spatial Change; C. Oberdoerster, Bayer AG / Crop Science - Exposure Modelling
Soils can be considered to be among the most essential bases of human life. It is a precious resource providing food and material, but also a diverse habitat for many organisms. In this habitat, soil organisms like earthworms may be exposed to many different stressors, such as environmental or anthropogenic stressors. Chemical stress, e.g. caused by agrochemicals, is addressed in the regulatory risk assessment which aims at preventing any adverse effects on the environment and its fauna. For soil organisms, the risk assessment is based on two key elements: the exposure and the effect assessment. Principally, the more advanced exposure models can take the spatial and temporal scale of chemicals into account. The effect assessment in the lower tier considers a limited temporal or spatial variability. However, in the example of earthworms, those scales play a major role as the species move vertically and/or horizontally through the soil and may change their burrowing behaviour in response to changing environmental factors. In this regard, modelling offers a powerful tool not only to overcome the gap between exposure and effect assessment, but also to increase the understanding of earthworm ecology. Taking into account chemical effects, e.g. caused by agrochemicals, toxicokinetic-toxicodynamic models are particularly suitable to make effect predictions for time variable exposure situations since they consider the underlying mechanisms. We will outline a modular approach and the challenges that need to be faced. Further, the results will highlight the importance of including the ecology and movement behaviour of earthworms in the risk assessment. Through linking the movement of the earthworms with the exposure scenarios already in use, a realistic exposure pattern can be identified. The TKTD approach will then complete the model by assessing survival probabilities in relation to experienced concentration levels. Our results emphasize that an increased ecological understanding is necessary to bridge the gap between exposure and effect assessment in soil. The suggested modular approach combines available methods for the exposure assessment with new methods to address the effects of plant protection products on earthworms. Integrated risk assessment by using a modular model approach linking exposure and effect models will provide sound higher tier refinement options for the risk assessment of soil organisms.

426
Applicability boundaries of the Equilibrium Partitioning Method (EPM) and alternative screening tools to predict toxicity to soil organisms
S. Gutierrez, ECHA / Biocides; S. MÖLKÄNEN, European Chemical Agency ECHA; c. carlon, ECHA-European Chemicals Agency; P. Karamertzanis,

European Chemicals Agency - ECHA; M.A. Bonnell, Environment and Climate Change Canada / Ecological Assessment Division; A. Gissi, European Chemicals Agency; M. Claessens, Chemours; A.D. Redman, Exxon Mobil Biomedical Sciences, Inc. / Toxicology and Environment Science Division; D. Jevtic, Syngenta / Product Safety; A. Kapanen, European Chemicals Agency - ECHA
According to REACH and BPR the equilibrium partitioning method (EPM) may be applied in some cases to assess the hazard to soil and sediment organisms in the absence of laboratory or field test. EPM is used to predict toxicity of substances based on results from aquatic toxicity assessment. The objective was to identify when the screening approach is adequate, what are its limitations, and in which cases further testing is needed to assess the toxicity to soil and sediment organisms. In addition, the project aimed to address the potential of other alternative screening tools within REACH and BPR. Data for this analysis was collected from the REACH registration database, and dossiers evaluated under Biocidal Products Regulation (BPR). Overall, the EPM method is protective in most cases, however, there is a clear indication that the selection of log Koc is an important factor on the accuracy of the prediction and should therefore be selected carefully. Alternative methods are, however, in their early stages and may not be applicable to all groups of organisms nevertheless could be used in conjunction to the EPM in a weight of evidence approach to support the conclusion o the toxicity to soil of a particular compound. The conclusions of this projects propose some suggestions to revise current guidelines for REACH and Biocides and identifyies areas for further development.

427
Verification of the current risk assessment scheme for earthworms by empirical evidence
P. Kotschik, Umweltbundesamt / Federal Agency of Environment / Risk assessment for plant protection products; T. Frische, Federal Environment Agency (UBA) / Section Plant Protection Products; K. Swarowsky, German Federal Environment Agency (UBA) / Department IV plant protection products; S. Pieper, German Federal Environment Agency (UBA) / Plant Protection Products
The risk prediction for soil organisms in agricultural used habitats due to the application of PPPs is based in a first step on standardized laboratory tests with earthworms in combination with predicted environmental concentrations (PECs) and an assessment factor of 5. If the Tier 1 risk assessment fails, field studies may be conducted to show whether unacceptable effects on earthworms will occur in the field under realistic conditions of use. In order to confirm the current evaluation process of PPP's and their actives in terms of applied soil depth as well as the used assessment factor in the first step of the risk assessment, all available field studies on earthworms of the database of the federal agency for environment (UBA) have been analyzed for a comparison with the outcome of the first step of the risk assessment in combination with three different soil depth: 1 cm, 2.5 cm and 5 cm. The survey identified 38 field studies fulfilling the current requirements according to [5]. To investigate the current regulatory context when evaluating submitted higher tier studies, the No Observed Effect Concentrations (NOEC) determined in the field studies were compared to the outcome of Tier 1 assessment steps. For the assessment of the protectivity of the current scheme, only field studies showing effects in terms of a Lowest Observed Effect Rate (LOER) were considered for the evaluation and compared to Tier 1 outcomes as in Table 1. In this case, 22 studies fullfilled the requirements. Independently from the sorptiveness of the active substances in soil, the choice of a soil depth of 1 cm for the calculation of the PEC in the first step of the risk assessment does not lead to the under-estimation of the 'real' risk for earthworm communities in the field based on the evaluated data. However, in approx. 25% of the analyzed cases, the choice of 5 cm soil depth for the calculation of the relevant PEC leads to an underestimation of effects in the field based on the first step of the risk assessment. As a consequence, the high protection level for soil organisms and biodiversity according to [2] might not be implemented. For the planned revision of the Guidance Document on Terrestrial Ecotoxicology, a calibration of a possible risk assessment scheme will need to take not only the comparison of field to laboratory data into account but also further source of uncertainties (e.g. [6 and 7]).

Adverse Effects of Chemicals on Host-associated and Free-living Microbiomes (II)

428
A novel metaproteomics approach to better assess the dynamics and functions of host-associated microbiomes from bioindicator species used in ecotoxicology
D.D. Gouveia, CEA - Marcoule / Laboratory of Innovative Technologies for Detection and Diagnostics; O. Pible, C. ALMUNIA, CEA; D. Degli Esposti, Irstea / UR RIVERLY Laboratoire Ecotoxicologie; a. chaumot, Irstea / UR MALY Laboratoire Ecotoxicologie; O. Geffard, Irstea / UR RIVERLY Laboratoire Ecotoxicologie; J. Armengaud, CEA / DRF/Joliot/DMTS/SPI/Li2D
Host-associated microbiota influences the life history traits of host animals and plays a major role in crucial apical endpoints such as survival, growth, resistance, and reproduction. However, the significance of these interactions in an ecotoxicological context has only been considered very recently. Data in the literature emphasizes the capacity of gut microbes to metabolize environmental chemicals and modulating their toxicity for the host. Because of the great importance of the interactions between the microbial community and its host, exposure to environmental contaminants may disturb this symbiosis and provoke effects in both host physiology and bacterial communities. In this work, we propose an innovative metaproteomics-based approach for microbiome analysis. By analyzing the peptide content of a given sample through tandem mass spectrometry, our approach allows for a quick taxonomic identification of the different organisms present in the sample, as well as their functional profile. The method allows identifying bacteria, archaea, yeasts, fungi, parasites, residual food and host biomarkers in one single analysis. Preliminary experiments have been done on midgut and hepatopancreatic caecum sampled from individual *Gammarus fossarum* animals. We could detect the presence of four main bacterial phyla dominating the microbiota: *Proteobacteria* (46%), *Firmicutes* (27%), *Actinobacteria* (24%), and *Bacteroidetes* (3%). More than 30 different genera could be differentiated and quantified. In addition, a global view of the main microbial metabolic pathways indicates the molecular functions associated with key processes for the host such as nutrition, digestion, and molt. Future studies will be conducted for assessing the role of microbiome dysbiosis in the health status of *Gammarus fossarum* upon different toxic stresses.

Associations between PAH pollution and environmental and human microbiota in kindergartens
M. Roslund, S. Rantala, A. Rantalainen, University of Helsinki; A. Sinkkonen, University of Helsinki / Faculty of Biological and Environmental Sciences
Today, more than half of the human population lives in urban areas that typically contain polycyclic aromatic hydrocarbons (PAHs). PAH contamination can change soil bacterial community composition. Since environmental microbiota is associated with human commensal microbiota, this contamination may in turn affect immune response and health. In addition, PAHs are known to cause direct health deficits, such as cancer. For these reasons, we investigated PAH pollution and environmental and human bacterial communities in kindergartens. We measured the concentrations of PAHs from the uppermost surface soil and air of eleven kindergartens yards in two city centres in southern Finland. Bacterial communities were analysed from soil and from children's skin, Each yard was sampled on five locations. To assess potential health hazards, we used the toxicity equivalent method i.e. converted observed soil PAH contamination to benzo(a)pyrene (BaP) total potency equivalents (tpe) We also simulated bioconcentration using SemiPermeable Membrane Device samplers to measure PAHs in the ambient air. There were three air samplers in each yard. For skin bacterial community analyzes, we collected children's swab samples from back of the hand. Bacterial communities in soil and on skin were analyzed using Illumina MiSeq 16S rRNA gene metabarcoding at phylum and OTU levels. Concentrations of fluoranthene exceeded environmental threshold value in two daycare yards. Benzo[a]pyrene concentrations were above the No Observed Effect Concentration for health in one sample. When benzo[a]pyrene total potency equivalents were used, the same sample was over two times higher than the allowed threshold for incremental lifetime cancer risk. Total PAHs were above background levels in several yards. In surface soil of daycare yards, bacterial communities were associated with PAH pollution as in our earlier studies. Interestingly, concentrations of individual PAH compounds in surface soil and in ambient air correlated with children's skin bacterial communities at phylum and OTU levels. We conclude that even subtle air pollution can result in surface soil concentrations that are higher than NOEC for health. In addition to the direct health consequences, PAHs may also change the abundance and diversity of human health-associated bacteria.

Are we blinded by the light? Increased chlorophyll fluorescence masks adverse effects in herbicide-exposed periphytic communities
A. Feckler, Swedish University of Agricultural Sciences (SLU) / Department of Aquatic Sciences and Assessment; J. Rakovic, Swedish University of Agricultural Sciences; M. Kahlert, SLU Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; R. Tröger, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; M. Bundschuh, Institute for Environmental Sciences University of Koblenz-Landau / Department of Aquatic Sciences and Assessment
Agricultural streams receive pesticide cocktails from arable lands during or following pesticide application. Among these pesticides, herbicides have been identified as the strongest pressure for algae and should consequently induce effects on periphytic structure and functioning. Although herbicide effects on periphyton have been frequently reported, the focus has yet been on herbicides that directly affect photosynthesis. The impact of herbicides with other modes of toxic action remains largely unknown. We therefore conducted a 21-days-lasting bioassay during which periphytic communities were exposed to the carotenoid-biosynthesis-inhibiting herbicide diflufenican for 12 days (up to 10 μg/L; n=4), followed by a 9-days-lasting recovery phase in herbicide-free medium. Every third day, periphytic pigment concentrations and algal community composition were

quantified by spectrophotometry and microscopic techniques, respectively. At the same time, periphytic functioning (photosynthetic efficiency and non-photochemical quenching [NPQ]) was assessed using pulse amplitude modulation fluorometry, which measures chlorophyll fluorescence and converts it into photosynthetic efficiency. When exposed to ≥0.2 µg diflufenican/L, periphyton showed 20-30% reduced chlorophyll a and carotenoid concentrations, likely explained by an up to ~35% reduced algal biovolume as well as diflufenican's mode of toxic action that shifted periphytic communities towards a higher heterotrophy. Simultaneously, the functioning in terms of photosynthetic efficiency surprisingly increased by up to ~15% under herbicide exposure judged on higher chlorophyll fluorescence. These unexpected findings may be explained by an up to 60% reduced NPQ as well as binding of diflufenican to the pigment-protein membrane complex of the photosystem II, two processes inducing higher chlorophyll fluorescence but not photosynthetic efficiency. Although increases in chlorophyll a concentrations and NPQ indicated some recovery potential during the second phase of the experiment, the persistence of a higher photosynthetic efficiency questions a quick recovery of periphyton from herbicide stress. While the processes underlying the observed functional shifts need further scrutiny, the potential shift towards a higher degree of heterotrophy in periphyton ultimately suggests an increasing importance of heterotrophic ecosystem functions in impacted stream sites over the long term.

431
Using bacterial efflux pumps as indicator of natural and anthropogenic stressors
J. Bodilis, LMSM; M. Hutinel, University of Lyon1; S. Michalet, Université Lyon1 / UMR Ecologie Microbienne; S. Nazaret, UMR CNRS 5557 / Laboratory of Microbial Ecology Université Lyon
The efflux pumps of the two primary RND (resistance-nodulation-cell division) families are phylogenetically close together and almost exclusively found in Gram negative bacteria. The first family (HME, for Heavy Metal Efflux) includes pumps that have been described as exclusively exporting metals, i.e. mono- and di-valent cations. The second family (HAE-1, for Hydrophobe/Amphiphile Efflux-1) includes pumps involved in the export of organic molecules toxic to bacteria, such as antibiotics, solvents, bile, detergent or aromatic molecules. Due to their very wide substrate specificity, many pumps belonging to this second RND family have been described as involved in the multi drug resistance (MDR) phenotype, but also in bacterial stress response and pathogenicity. Our study aimed to compare the distribution of RND pumps according to taxonomy, origin, pathogenicity and more generally the ecology of bacteria in various environments. First, we reconstructed pump phylogeny of these two RND families from 920 genomes representative of the known diversity of Gram negative bacteria. Then, we confirmed putative ecological roles of some RND pumps by quantifying RND genes in environmental samples (qPCR) using primers targeting HAE-1 and HME families. Interestingly, we found a higher number of genes encoding HME pumps in genomes of bacteria isolated from metal contaminated environments (2.66 genes per genome vs 1.13; $P < 10^{-6}$), indicating that the HME pump gene is a relevant indicator of metal contamination in soil. More surprisingly, a higher number of genes encoding HAE-1 pumps was found in bacteria isolated from the rhizosphere compared to bulk soil (6.47 vs 4.25; $P < 10^{-6}$), while no significant difference was observed between pathogens and no pathogens in human associated bacteria. Our result raises the question of the role of root environment in the emergence of MDR phenotypes in opportunistic human pathogens. Finally, we identified a new RND clade, probably a cryptic RND family, linked to marine environment. Overall, because these results show that RND pumps are linked to bacterial lifestyles, the quantification of their gene and probably their expression could be used as indicator of natural and anthropogenic stressors.

432
Effects of glyphosate-based herbicides on non-target avian taxa: development and gut microbiome
S. Ruuskanen, M. Rainio, University of Turku / Department of Biology; V. Kuosmanen, University of Jyvaskyla; C. Gomez-Callego, University of Eastern Finland; O. Selenius, University of Turku / Functional Foods Forum; M. Collado, IATA-CSIC; S. Salminen, University of Turku / Functional Foods Forum; I. Saloniemi, University of Turku / Department of Biology; K. Saikkonen, University of Turku / Biodiversity Unit; M. Helander, University of Turku / Department of Biology
Glyphosate-based herbicides (GBHs) are the most commonly used herbicides globally. Glyphosate has long had a reputation of being non-toxic to animals, but this has recently been challenged. GBHs have shown to influence physiology, express genotoxic and teratogenic effects, with a study focus on mammalian laboratory vertebrates. Furthermore, due to the presence of GBH-sensitive EPSPS enzyme in microorganisms, GBHs may also fundamentally influence animal gut microbiome. Developmental exposure to GBHs is likely to be more detrimental than exposure during adulthood, but this has not been thoroughly studied. Potential sex-specific effects are also poorly understood. We studied the effects of long-term exposure to a moderate dose of oral GBHs on development and gut microbiome in Japanese quail (*Coturnix japonica*) males and females. GBH and control treatments (N = 38/group) were started at 10-day old hatchlings and growth, plumage development, reproductive maturation and gut microbiome (at the age of 12 and 28 weeks) were analyzed. GBH treatment did not influence growth in either male or female quails. GBH treatment delayed plumage development especially in females. Egg production nor male sexual maturation was affected by GBHs. However, glyphosate residues were detected in eggs, and thus may influence embryo development. We expect GHBs to decrease general gut microbial diversity, and especially *Firmicutes* abundance. These results are of important value for both poultry industry – especially as currently glyphosate concentration in animal feed is not regulated – as well as wildlife and humans, to increase our understanding the multitude of GBH-related effects on vertebrates.

433
Differential evolution of archaeal compared to bacterial communities rendered new biomarkers of multipollution events in Mediterranean coastal rivers
M. Noyer, B. Reoyo-Prats, CEFREM UMR 5110 CNRS-UPVD; M. Bernard, INRA GABI; O. Verneau, C. Palacios, CEFREM UMR 5110 CNRS-UPVD
Microbiomes are essential for the proper functioning of aquatic environments but anthropogenic stressors can lead to spatial and temporal evolutions of microbial communities and affect ecosystems fonctions and services. Assessing the environmental impact of xenobiotics in aquatic microbiomes represents nowadays a fundamental issue. Concentrations of pollutants in watercourses depend on numerous factors such as land use and rainfall events. We have demonstrated that storm events are at the origin of multipollution episodes in Mediterranean coastal rivers, which are chronically submitted to regimes of droughts and floods in these regions. In this study, we aimed at understanding how these sudden contaminant changes during flood events impact the diversity of particle-attached microorganisms of the Têt River, a major coastal watercourse in the South-East of France. Bacterial structural changes inferred through high-throughput sequencing of the 16S rRNA gene occurred at two particular moments of a major flood event: during the flow peak and during combined sewer overflows (CSOs), at which multipollution phenomena were detected by a parallel in-depth study of contaminants presence. The archaeal microbiome evolved in four distinct community groupes, which did not coincide with the four phases of the flood as for the bacterial microbiome. Nevetheless, changes ocurred from the first peak of multipollution too. Constrained multivariate analyses confirmed significant differences between communities for both microbial compartments and changes coincided with significant pollutant mixtures dynamics in tested models. *Thaumarchaeota* was virtually the only *phylum* just after the flow peak, while *Euryarchaeota* dominated certain samples during CSOs and at the flow peak. Major Archaea genera are related to the nitrogen cycle and to methanogenesis. Characteristic OTUs related to cocktails of pollutants from both domains will be highligted, constituting early biosignatures of multicontamination stress.

Novel Developments in Testing Chemicals for Endocrine Disrupting Properties (II)

434
An EU-NETVAL validation study on in vitro methods to inform on thyroid disruption potential
A. KIENZLER, JRC-EC / F3-Chemical Safety and Alternative Methods Unit-EURL ECVAM; S. Coecke, European Commission, Joint Research Centre / F3 - Chemical safety and alternative methods unit; S. Munn, European Commission, Joint Research Centre
Significant progress has been achieved recently in the EU for the regulation of endocrine disruptors (EDs). However, there are still important gaps in the available test methods to accurately assess EDs potential of chemicals. In particular, *in vitro* methods to inform on thyroid disruption potential are still lacking. To fill this gap, EURL ECVAM launched a call to EU-NETVAL members in 2017 for participation in a validation study of a set of mechanistically informative alternative methods focusing on thyroid disruption, and is now coordinating this validation study in collaboration with EU-NETVAL laboratories and the developers of the methods. A total of 17 methods have been chosen, because they are complementary and cover the main possibilities of interaction with the thyroid signalling pathway, grouped in eight blocks: (1) central regulation, (2) Thyroid Hormone (TH) synthesis (3), secretion and transport in serum of THs (4) metabolism and excretion of THs (5) local cellular concentrations, (6) cellular responses. Furthermore, the validation study also consider relevant short term *in vitro* methods (7) integrating multiple Modes of Action, and (8) integrative cellular *in vitro* methods. The prioritisation of the methods has been done according to the following criteria: 1. At least one thyroid method should cover each of the 8 blocks 2. If possible, the methods should be suitable for high-throughput approaches 3. Methods are based, whenever possible, on the use of human-derived test systems 4. The test systems (cells, cell lines, microsomes, proteins..) availability should be taken into account Fourteen EU-NETVAL facilities have been assigned to work on the selected methods. The validation study consists of two parts: part one defines the methods and assesses their transferability and reliability; part two is focused on the overall relevance of the methods. It will comply with the recently published OECD Guidance on Good

In Vitro Method Practices (GIVIMP). For each of the methods, outline protocols will be drafted including definition of the test systems used as well as the control and reference items. Those methods which perform best will be selected for further assessment in support of EU and OECD strategies to address the potential risks to human health and the environment posed by thyroid disruptors. The validation results will also be used to inform Integrated Approaches to Testing and Assessment (IATA) for the identification of thyroid disruptors.

435

Effects of perchlorate on the metamorphosis of the common frog Rana temporaria

P. Bjerregaard, University of Southern Denmark / Biology; J. Morthorst, University of Southern Denmark / Department of Biology

Amphibian populations are in decline all over the world and they are the most threatened group of vertebrates. The only amphibian species used in the OECD guidelines for the test of endocrine disrupting properties are tropical, 100% aquatic species (*Xenopus sp*.) which have a very different mode of life compared to species living in temperate areas. No other standardised tests exist and this potentially results in severe shortcomings in the risk assessment of chemicals with regard to amphibians - as pointed out in a recent report from EFSA. The EFSA report shows that the risk assessment of the effect of e.g. pesticides on amphibians is very insufficient and there is a need to include endemic, temperate amphibian species into the test guidelines. Here we examine the effects of compounds with known effects on thyroid regulation in the common frog *Rana temporaria*. The effects of perchlorate will be compared to the effects in *Xenopus laevis*. Perchlorate inhibits iodine uptake in the thyroid glands by competitively inhibiting the thyroid sodium-iodide symporter (NIS). The experimental design was as close to that of OECD TG241 as possible. Clutches of fertilised eggs were collected from a pond with at least 50 breeding frogs in early April of 2018. Fifty eggs were placed in each of 24 glass aquaria with 6 L of water in a flow-through setup. Water and stock solution of perchlorate were supplied by peristaltic pumps at a water flow of 30 L per day. Temperature was16±1 °C. Four replicate aquaria were used for each exposure concentration (12, 41, 131 & 427 μg/L) - except that 8 aquaria were used in the control group. Exposure concentrations were determined by means of LC-MS-MS (Agilent 6410) and they were very stable during the experiment. At the end of the experiment June 6-8 2018, the animals were weighed and the length of the body and legs were recorded and Gossner stage determined. One half of the animals were fixated for histological analysis of the thyroid gland and the other half was frozen for hormone determination. Data from the experiment are being processed winter and spring 2018-2019 but one of the initial findings upon the histological examination is that exposure to perchlorate results in a reduced amont of liquid in the follicles of the thyroid glands. Similar effects have been observed in *X. laevis* upon exposure to perchlorate. In conclusion, it is possible to conduct experiments with endemic European frogs reflecting the conditions of OECD TG241.

436

Environmental applications for in vivo thyroid active molecules identification with the XETA (Xenopus Embryonic Thyroid Assay)

D. Du Pasquier, Watchfrog S.A.

Amphibians are primary targets in the ecosystem for environmental pollutants. Surface waters can contain a diverse range of pollutants, including Plant Protection Products, pharmaceuticals and industrial compounds. Numbers of chemicals or environmental samples have been identified to possess thyroid activities. Amphibians are particularly sensitive to thyroid disruption because metamorphosis is a thyroid-dependent processes that is fundamental for amphibians. Identification of thyroid disrupters in amphibians is therefore of high concern in the context of the decline of amphibians' populations. OECD validated already two guidelines for the identification of thyroid active molecules in amphibians: The AMA and the LAGDA. These two assays are fit for purpose for the regulatory testing of chemicals at low throughput but not to screen molecules at higher throughput or to test environmental samples that couldn't be stored or sampled in large quantities. We developed the Xenopus Embryonic Thyroid Assay to offer an amphibian screen for thyroid active molecules and environmental samples. The assay is transcriptional-based, and uses a transgenic tadpole line containing the THbZIP-GFP genetic construct to detect the activity of thyroid active molecules that work through various mechanisms. The XETA is currently being validated by the OECD and it is expected that the XETA will be approved as a test guideline in April 2019. Here to illustrate the benefit of this new tool for the hazard assessment of endocrine active chemicals we describe several applications. In the SOLUTIONS project, we assessed chemicals selected from the list of substances identified as relevant European river pollutants. Among 20 tested chemicals, the XETA identified 9 thyroid active substances. The data mining exercise highlighted for almost all positive chemicals the lack of existing data for thyroid activity in Amphibians. OCDE validation focus on using the XETA to test pure chemicals but this test could be particularly useful for the hazard assessment of effluents. During the 12 past years we applied this assay to effluents including wastewater, treated wastewater, hospital effluents, water from industrial processes. Our results using the XETA showed daily variations of the thyroid effect in wastewater, linked to economic activities and rainfall and highlighted that most WWTP effluent still contains molecules presenting thyroid activity for amphibians that are released into the environment.

Assessment of potential endocrine disrupting properties using in silico tools - first experiences under the new EU Guidance Document

A. Gerloff-Elias, M. Duft, R. Gonella Diaza, knoell Germany GmbH

In silico procedures have gained more and more acceptance by regulatory agencies in the last few years. These methods describe computer-based calculation models based on the hypothesis that similar structural features lead to similar effects or properties. In the recently published Guidance on the identification of endocrine disruptors under Regulations (EU) No 528/2012 and (EC) No 1107/2009, *in silico* predictions are suggested to be used to generate supporting information for endocrine modalities within a weight of evidence (WoE) approach. An overview of available software tools for predicting potential endocrine activity is given in the new Guidance for the identification of endocrine disruptors (EFSA Journal 2018). It should be noted that the application of *in silico* methods for the assessment of potential endocrine-disrupting chemicals is particularly challenging due to the inherent complexity of the endocrine system itself. While the scientific understanding of the endocrine system and testing methods for the purpose of regulatory human health and environmental risk assessments have advanced in recent years, *in silico* methods for assessing the potential of endocrine activity or endocrine disrupting properties is lagging. In this respect, it is noteworthy that among the aims of the recently initiated European research project (LIFE CONCERT REACH) in which six research institutes and consultant companies are participating, the development/integration of new models for predicting potential endocrine activities, within the VEGA software platform [www.vegahub.eu] is anticipated. QSAR models are typically restricted in their applicability depending on the chemical space in which they have been developed. Indeed, the reliability of results is highly dependent on the quality of the underlying dataset and the similarity of the assessed substance to those comprising the dataset used for the model development. In this presentation, we will address the challenges encountered when using a battery of *in silico* tools predicting various pathways for endocrine disruption. Furthermore, we will summarise our first hand experiences of using *in silico* models in the context of the application of the new Guidance for the identification of endocrine disruptors and how contradicting results have been addressed.

A nuclear and membrane oestrogen receptor assay to test the oestrogenic activities of pollutants in fish

C. Moreira, Universite du Havre / UMR-I 02 INERIS-URCA-ULH Environmental Stress and Aquatic Biomonitoring (SEBIO); C. Zapater, Instituto Acuicultura de Torre de la Sal, CSIC; P.I. Pinto, CCMAR Centre of Marine Sciences; T. Knigge, Normandy University ULH / UMR-I 02 INERIS-URCA-ULH Environmental Stress and Aquatic Biomonitoring (SEBIO); A. Gómez, Instituto Acuicultura de Torre de la Sal, CSIC; T. Monsinjon, Normandy University ULH / UMR-I 02 INERIS-URCA-ULH Environmental Stress and Aquatic Biomonitoring (SEBIO)

Oestrogenic compounds are well known endocrine disruptors. In aquatic ecosystems, these compounds may derive from natural (e.g. phytoestrogens) or anthropogenic sources (e.g. pharmaceutical products such as contraceptives or antidepressants) and a continuous exposition to these pollutants may threaten animals' health. Oestrogens are important regulators of multiple physiological processes and oestrogenic actions are mediated across vertebrates by binding to several oestrogen receptor types. Specific transcription factors, designated nuclear oestrogen receptors (Esrs), have been mainly associated with the classical activation of gene expression by oestrogens or structurally similar compounds. More recently, membrane receptors such as the G protein-coupled oestrogen receptor (Gper) have been associated with rapid, non-genomic responses to estrogens. Both signaling pathways are present in fish, which express additional gene duplicates for both receptor types, although relative oestrogenic activities to the different receptors may differ between species. Using transient transfections in the human embryonic kidney cell line HEK293 and an ERE-luciferase reporter gene assay, the activation of sea bass Esrs was studied in response to of two compounds, the phytoestrogen genistein and the antidepressant and emerging pollutant fluoxetine (Prozac®). In addition, the activation of the two recently identified sea bass Gper duplicates was evaluated using a cAMP response element-luciferase reporter gene assay. Results indicate that genistein and fluoxetine affect each nuclear receptor in a different manner: Fluoxetine rather triggers an anti-oestrogenic response, while genistein behaves as an oestrogen mimic in the transactivation of the three Esrs. Oestradiol was able to induce luciferase activity in cells transfected with both membrane receptors, confirming, for the first time, that both teleost gene duplicates are functional. Furthermore, several xenoestrogens also stimulated luciferase activity and G1 and G15 were confirmed as agonist and antagonist of sea bass Gper, respectively. This study also demonstrates the suitability of the luciferase reporter assay as a tool to assess the oestrogenic potency and mechanisms of action of a wide variety of chemicals. Potential risks of the exposure of fish to various compounds in the environment or in aquaculture can be efficiently identified.

439

Use the Right Tool for the Job! Mechanistic Potency Is Essential for Hazard Identification

E.M. Mihaich, ER2; C. Borgert, Applied Pharmacology & Toxicology, Inc.

Regulatory initiatives for identifying and managing chemical endocrine disruptors (EDs) are being developed and implemented in several jurisdictions in response to concerns that exogenous chemicals may interfere with the endocrine systems of humans and environmental organisms. According to the World Health Organization's International Programme on Chemical Safety, an ED must (1) alter the function of the endocrine system; and (2) as a consequence of that alteration, cause an adverse health effect in humans or wildlife. This definition requires a causal link between the endocrine mode of action (MoA) and the adverse effect. However, with the publication of the ECHA/EFSA guidance for the identification of EDs, this requirement for a causal association appears to have shifted to one that is "biologically plausible." This is a very different criterion, especially when the guiding regulatory approach is one of hazard and not risk. Pathway models are being established that provide plausible links between molecular initiating events, key events and ultimately adverse effects. However, when several potential pathways or MoA converge on the same adverse effect in an intact organism it becomes challenging to identify the biologically plausible *causal* link between the MoA and the environmental or health effect of concern. To minimize the risk of misidentification of an endocrine MoA, an objective and transparent weight of evidence (WoE) procedure based on biological plausibility, essentiality, and empirical evidence is recommended. In order to determine whether it is biologically plausible that a chemical produces an adverse effect via an endocrine MoA, i.e, that it might fit the definition of an ED, the mechanistic potency must be evaluated to measure the strength of a chemical's activity via a specific endocrine MoA. We present a case study that applies a recently published potency threshold methodology (Borgert et al. 2018) to two chemicals identified on the Danish List of Endocrine Disrupters, a cyclic siloxane and bisphenol A. Mechanistic potency was evaluated along with other relevant information in a WoE framework to determine the potential for the chemical to meet the definition of an ED.

Improving Decision Support for Sustainability Going beyond Standard LCA (II)

440

Uncertainty of product systems in LCA of emerging technologies

C. Blanco, Institute of Environmental Sciences, Leiden University / Industrial ecology / Environmental Biology; S. Cucurachi, R. Heijungs, CML Leiden University / Industrial Ecology; M.G. Vijver, CML Leiden University / Environmental Biology; W. Peijnenburg, RIVM / Center for Safety of Substances and Products; J. Guinee, University of Leiden / Institute of Environmental Sciences CML

With the recent drive to use LCA to assess the environmental impacts of emerging technologies, new and increased sources of uncertainty have become relevant. These are mostly related to the unpredictable evolution of the manufacturing pathways that are chosen as the technology moves from lab to industrial scale. The same applies to the multiple and/or unforeseen ways in which the technology will be used, disposed and/or recycled. Several LCA studies of emerging technologies have opted to address these uncertainties by assessing different scenarios which allow practitioners to make if/then types of conclusions. However, multiple if/then conclusions can only offer limited guidance for policy decisions that must be made with the current state of knowledge. The scenario-based approach also brings a problem of a more practical nature; considering all the different possibilities, the number of scenarios can quickly become unmanageable. We present a framework in which possible future configurations of a technology's product system are assessed as a single product system with uncertain components. The uncertain components are unit processes in the manufacturing, use, and/or end-of-life stages which may or may not be used in an industrial scale implementation of the technology. For this we set up a product system that includes all alternative unit processes, and then randomly activate or deactivate them according to defined probabilities of occurrence. This method allows us to run a Monte Carlo simulation on the single product system to obtain a single probability distribution for each impact category. The resulting distribution accounts for uncertainty about the product system's final configuration, along with other sources of uncertainty e.g in the background systems or other modelling choices. Our framework provides a way to investigate whether an emerging technology is likely to outperform the incumbent technology. It distinguishes itself from scenario-based approaches, which are better suited to identify which of the possible scenarios are preferable from an environmental point of view. Our approach is more adequate for a situation where there is no actual choice, rather uncertainty about which processes will enable the technology in the long run, which is often the case. We therefore advocate for a clear distinction of the goal of the LCA in each case, and use of the appropriate framing to achieve it.

441

Prospective inventory modelling of emerging chemicals: The case of photonic materials

R. Arvidsson, Chalmers University of Technology / Environmental Systems Analysis; D. Kushnir, Lund University / CIRCLE; M. Janssen, Chalmers University of Technology / Technology Management & Economics; B.A. Sandén, Chalmers University of Technology / Environmental Systems Analysis

Prospective life cycle assessment (LCA), or ex-ante LCA, has been defined as an assessment of a product system modeled at a future time, before its commercialization. Such assessments bring the promise of altering emerging technologies in a more environmentally benefitial direction before they become difficult to change. Since the future cannot be known with certainty, prospective modeling need to rely on scenarios of various kinds. However, how to conduct such prospective scenario modeling in practice still has to be clarified. In this study, we have modeled two emerging chemicals that can be used for a technology called photon upconversion, which converts low-energy light into higher-energy light harvestable by solar photovoltaics, thereby increasing their efficiency. Two chemicals currently considered for this purpose are ruthenium bipyridine chloride (RBC) and diphenylanthracene (DPA). These novel, emerging chemicals have not been studied regarding environmental performance before and are consequently not present in any LCA databases. The aim of this study is to present a generic procedure for prospective inventory modeling of emerging chemicals and apply that to the cases of RBC and DPA by developing unit processes for these two chemicals. An industrial synthesis scenario was adopted as our main scenario, reflecting a possible future time when RBC and DPA are produced at an industrial scale. The modeling was conducted in six steps: (1) Identify likely chemical syntheses. (2) Calculate inputs stoichiometrically based on the chemical synthesis reactions. (3) Modify inputs based on available yields for reactants and solvents (e.g. obtained from patents or estimated). (4) Categorize outputs as by-products or waste depending on their likely subsequent fate. (5) Calculate process emissions. (6) Model energy flows. Unit processes for the two emerging chemicals are thusly developed. The procedure is considered particularly strong for estimating inputs and output materials related to the stoichiometric reaction, but weaker regarding the estimation of emissions and energy requrement. Further research into the modeling of energy flows for high-temperature processes is therefore recommended, as well as estimation procedures for emissions from emerging chemicals production.

442

Ex-ante life cycle assessment of the cumulative energy demand of a perovskite solar cell

S. Weyand, TU Darmstadt / Institue IWAR, Chair of Material Flow Management and Resource Economy; K. Kawajiri, National Institute of Advanced Industrial Science and Technology (AIST) / Research Institute of Science for Safety and Sustainability; L. Schebek, Technische Universitaet Darmstadt / Institute IWAR Material Flow Management and Resource Economy Germany

The perovskite solar cell (PSC) has shown an outstanding evolution from power conversion efficiency of 3.8% in 2009 to 23.3% in 2018 [1] and is the most promising emerging photovoltaic technology (PV). However, from a life-cycle point of view, other emerging PVs with lower maximum efficiencies such as organic PV (OPV) with 12.6%, seem to be more promising. From a review of the respective publications, however, it can be shown that the OPV impacts results are drawn from ex-ante LCAs of prospective OPVs, whereas the PSC impacts results are based on existing lab-based data in ex-post LCAs. We conclude that there is a connection between higher cumulative energy demands (CED) and overall higher environmental impacts due to lab-data, whereas CED of commercial production can be expected to be considerably lower. To verify this assumption, we developed a novel approach to scale up the CED of PSC manufacturing processes. In the following, we present our approach and compare our CED results to recent LCA studies on PSC and OPV. We differentiated three upscaling scenarios A), B), and C) whereas the CED of A) is reduced by 50% to B) and by 80 % from B) to C). The CED of A) is comparable with the PSC literature estimates since we only applied linear upscaling without scale effects. Our calculated CED is lower than the median of the PSC literature what might result partly from the unknown processes but also from differences in the considered embedded materials and manufacturing processes of each reviewed LCA study. Scenario B) and C) are comparable with the OPV literature since both scenarios integrates scale effects considering that manufacturing processes of industrial PSCs run more efficiently than of lab-scaled. In scenario B), this efficiency is displayed by the integration of process-specific scaling factors. Scenario C) is independent from the lab-data and has the lowest CED impacts. That is not the case in general but results from inefficient lab devices which affect scenario B) but has no impacts on C). In case of devices with efficiencies above the average, scenario B) would lead to higher scale effect and result in lower CED than scenario C). The presented approach can be applied to get more realistic results of ex-ante LCA for commercial production of prospective PSC. Furthermore, the approach can be easily transferred to other emerging technologies and support the performance of ex-ante LCA at a very early stage of technology development.

443

Integrated ex-ante environmental and techno-economic assessment of plasma gasification for enhanced landfill mining

G. Sauve, KU Leuven / Materials Engineering Department; J. Esguerra, J. Krook, N. Svensson, Linköping University / Department of Management and Engineering; S. Van Passel, Department of Engineering Management, Faculty of Applied Economics, University of Antwerp; K. Van Acker, KU Leuven / Materials Engineering

When addressing new waste management systems, an in depth analysis of the possible system design alternatives and their environmental and techno-economic performances is required to support decision making. New approaches are needed for early stage assessments of emerging waste management technologies to address the uncertainties associated to alternative system design concepts, upscaling and lack of data. In particular, it needs to account variability of site-specific conditions such as different waste feedstock, uniformity of scale among (sub)processes, and limited primary data due to lack of commercial implementation. Results from environmental and economic assessments could then be more reliable for supporting decision making. This study addresses the potential of plasma gasification as combined material and energy valorisation technology for exacavated landfill waste in the context of enhanced landfill mining (ELFM). Main products of plasma gasification are a high quality syngas, metals and a vitrified slag which can be used for the production of new construction materials. However, plasma gasification is still an emerging technology which has mainly been studied at pilot scale. Different design alternatives should be considered when assessing its feasibility at commercial scale, including feedstock composition, gasifying agent, etc. The goal of the study is to understand which critical factors mostly influence the techno-economic and environmental performance of the process and how their variation can affect the outcome, and under which conditions the technology would represent a viable solution for combined energy and materialrecovery. The ex-ante integrated economic and environmental assessment is conducted through a factor based-approach and multiple-scenario analysis. 8 critical performance factors are identified for plasma gasification at a system, project and site-level. For each factor, 3 alternative datasets are considered. A factorial number of scenarios (3^8=6561) is built as unique combination of the factors and their datasets The scenarios simulate alternative technology designs and ranges of performances. Equilibrium models are then applied to calculate mass and energy balances for the scenarios and address the upscaling issues related to the assessment at industrial scale. A variance based sensitivity analysis is eventually conducted to identify the most relevant factors in the techno-economic and environmental performance.

Challenges of prospective life cycle assessment of emerging cell-culture based technologies for food production

H. Tuomisto, University of Helsinki / Helsinki Institute of Sustainability Science (HELSUS) and Department of Agricultural Sciences

Due to the environmental challenges related to agriculture and livestock production, researchers have started to develop cell-culturing based technologies for producing food and materials (i.e. cellular agriculture). The products of cellular agriculture are divided in two groups: cellular products and acellular products. Cellular products consist of the actual cells that have been cultured, whereas acellular products are proteins or other substances that are synthesized by the cultured cells - generally microbial cells. Cultured meat (i.e. in vitro meat, clean meat or cell-based meat) is an example of a cellular product, and it consists of livestock muscle cells that are cultured in a nutrition medium in a bioreactor. The range of acellular products is wide, including proteins, fatty acids and many other substances. A few prospective life cycle assessment (LCA) studies have estimated the environmental impacts cultured meat, but peer-reviewed LCA studies of the acellular products used for food are currently missing. This paper discusses the challenges of carrying out prospective LCAs for applications of cellular agriculture. Three products of cellular agriculture are used as case studies: i) cultured meat, ii) egg albumin synthesized by a fungus and iii) microbial single-cell protein. The level of challenges to perform an LCA vary depending on the product. Cultured meat had the highest uncertainties due to scarcity of knowledge of the design of large-scale production systems. The results of the previously published prospective LCA studies of cultured meat differ substantially depending on the whether they are based on currently available technologies or assume the use of possible future technologies. The second technology, egg albumin synthesized by a fungus, was less challenging due to existence of similar technologies that currently operate in large-scale production. (i.e. production of enzymes). Therefore, the main challenges were related to the assumptions of the similarity of processes (e.g. protein yields and composition of nutrition medium) access to data due to confidentiality reasons and availability of LCA data for the inputs. Regarding the microbial single-cell protein, the main challenges were related to the low technology readiness level, and therefore, difficulty to estimate the level of technological development related to the process itself and supporting processes (e.g. energy generation by solar panels and hydrolyses process).

Assessment of Social Impacts for Decision-Making Processes and Communication

446

A critical review of impact assessment in socio-economic analysis of REACH restriction dossiers

S. Gabbert, Wageningen University / Social Sciences; I. Hilber, Agroscope ART / Environmental Analytics

Under the European chemicals legislation REACH, regulatory authorities of EU member states or the European Chemicals Agency (ECHA) can submit proposals for adopting measures that restrict the use of substances posing an unacceptably high risk to society. Such restriction dossiers usually include a socio-economic analysis (SEA), providing detailed information about the expected positive or negative impacts of one or more risk management options (RMOs). REACH guidance documents suggest to assess different types of impacts, i.e. economic, environmental, human health, wider economic, social, and distributional impacts. Comparing the impacts of one or more RMO(s) against impacts of a business-as-usual scenario (i.e. impacts without a restriction) supports decision-making on the selection of the preferred RMO. Conducting an impact assessment in a REACH restriction proposal is time- and resource consuming. Obvious questions are, therefore, how impact assessments in REACH restriction dossiers were conducted, what results were obtained, and how these results contributed to decision-making. This study offers a systematic and critical evaluation of the impact assessment in REACH restriction dossiers. First, we identify the types of impacts assessed. Second, we evaluate the methodological approaches used for assessing impacts. Third, we compare the outcomes of impact assessment across dossiers. Particular attention is given to the expected risk reduction capacity of the suggested RMOs, their expected costs, and their expected (quantifiable) benefits. Finally, we analyse whether the outcomes of impact assessment systematically differ between chemicals belonging to Substances of Very High Concern (SVHC) and those which are non-SVHC. Our findings underline that impact assessment in SEA in REACH restriction dossiers is not based on a holistic approach. Furthermore, assessments have focused on selected impacts only, particularly on economic and health impacts. The assessment of economic impacts has been focusing on direct costs (compliance and substitution costs) only, but has largely ignored external costs. Hence, results from impact assessment do not warrant conclusions about the social impacts resulting from a proposed restriction. While this can sometimes be explained by the very specific scope of a restriction dossier, we also observe a lack of approaches for assessing environmental, health, social, and distributional impacts from chemicals use.

447

Communicating carcinogenicity findings for layman: How much safer will painting be after TiO2 carcinogenicity classification?

E. Kähkönen, Aalto University / Aalto Design Factory

The decision-making processes related to the implementation and application of REACH and CLP-regulations aim at *ensuring a high level of protection of human health and the environment*. Tools of these regulations range from bans on substance use to warnings on substances to users. Evidently, bans define new rules for a business around a banned substance and, hence, cause social impact. However, even less severe changes in the regulatory status of a substance will have impacts on the substance use, business, and society. Current process on the classification of titanium dioxide (TiO_2) as a carcinogenic substance provides a topical example of a regulatory process. The proposed classification does not ban the use of TiO_2, but sets new requirements on hazard communication regarding the substance. Our aim was to assess impacts of the new classification on the whole product life cycle from raw materials to products and finally to the end of life stage. We used a stepwise approach in which we studied the process from the hazard assessment results to the expected goal of improved chemical safety in five steps. First, we summarized the findings on current TiO_2 exposure. Second, we compared theTiO_2 hazard assessments outcomes. Third, we studied ECHA's hazard classification process on TiO_2. Four, we searched relevant (for TiO_2) guidance tools, which refer to the hazard classification, such as eco-labels, product regulations, recommendations for purchasing, and company policies. Finally, we compared exposure to TiO_2 with carcinogenicity classification and the original exposure throughout the product life cycle. Our conclusion was that the classification of TiO_2 as a Carc Cat 2 substance would not have an impact in exposure and related chemical risks. From communication point of view, we saw a challenge in attaching standard health hazard warning in liquid products, such as paint, when the potential hazard is associated with dry TiO2 particles. On the other hand, we question the message of warning consumers on carcinogenicity in cases in which authorities have challenges in the interpretation of the toxicity assessment results. Is the intended communication with the warning: "We don't know for sure - Use at your own responsibility"? We underline that there is a risk for inflation of hazard communication along with the increasing prevalence of warning labels.

Revision of the Guidelines for Social Life Cycle Assessment of products - status and progress
M. Traverso, RWTH Aachen / Institute of Sustainability in Civil Engineering; C. Benoit-Norris, NewEarth B; E. Ekener, KTH royal Institute of Technology; M. Finkbeiner, DaimlerChrysler AG / Chair of Sustainable Engineering; A. Lehmann, Technische Universitaet Berlin / Chair of Sustainable Engineering; S. Neugebauer, RWTH Aachen University / INaB Institute for Sustainability in Civil Engineering; S. Russo Garrido, CIRAIG, UQÀM / École des Sciences de la gestion; S. Valdivia, Leuphana University of Lüneburg / Faculty of Sustainability; F. Wang, UN Environment Life Cycle Initiative
Lots of efforts have been undertaken in the last ten years to further development the Social Life Cycle Assessment (S-LCA) methodology. It is defined as the assessment of positive and negative social impacts of a product along its life cycle. The economic crisis and the globalized market led to the necessity to more transparent supply chains and to measure the impact generated by a product/ company on the different stakeholders involved in the supply chain. The first S-LCA Guidelines were published in 2009 by the UNEP/SETAC Life Cycle Initiative. Those were complemented by the related Methodological Sheets in 2013 (UNEP, 2013). Since the launch of the 2009 and 2013 publications, many S-LCA case studies have been conducted, and methodological improvements, i.e. the special issue on Social life cycle assessment, (Macombe et al 2018) have taken place. At the same time, similar initiatives from the business world were developed: e.g. development of the Handbook of Product Social Impact Assessment (2018) released by the Roundtable of Product Social metrics in different versions (2016, 2018). Building on the existing literature, research activities and initiatives, experts in the field joined the "Social LC Alliance" effort to review the S-LCA Guidelines 10 years after its original publication by bringing a critical update. This Social LC Alliance project started in September 2017 as a flagship activity of the 5th phase of the UN environment Life Cycle Initiative. The project consists of two phases: 1) revision of the Guidelines and 2) Implementations of the new version of the Guidelines throughout new case studies. The process takes place also in cooperation with the 10YFP Consumer Information Program. The review process undertaking includes experts from all sectors (academia, business, government, NGOs,) working in small groups by topic. A comprehensive peer review process will be launched in 2019. The new capability-development format will support broadening the practice by making the Guidelines a cornerstone reference for anyone wanting to conduct a S- LCA, Social Organizational Life Cycle Assessment, Social Hotspots Assessment or a Human Rights Due Diligence Assessment. An overview of the new S-LCA Guidelines draft will be given with the description of the new aspects included as well as a description of the consultation process and inputs received to finalize the Guidelines.

449
Stakeholders Categories for S-LCA application in social business: People T&C case study
G. Arcese, Università Niccolò Cusano / Business Studies; M.C. Lucchetti, Roma Tre / Business Studies; M. Colatosti, People T&C; O. Martucci, Università degli Roma Tre / Department of Business Studies
The interconnection among the three sustainability pillars (people, planet and profit) has been underlined over the last time. Several studies and research refer the sustainability to the political and cultural dimension of societies. In the S-LCA context, it is possible to say that, a society is developing socially and economically within an environmentally conditioned context and this development is directed dependent by the strategical and political organization (Mazijn, 1994). Among the activities of the joint research project between the Department of Business Studies and People Srl. with the aim of developing an innovative model to stakeholder's management based on participatory approach to improve and develop territorial networks, after a preliminary internal survey, the stakeholder categories and sub categories was defined in order to implement Social Life Cycle Assessment framework. Social Life Cycle Assessment is a technique available to account for stories and inform systematically on impacts. May it help stakeholders to effectively and efficiently engage to improve social and socio-economic conditions of production and consumption (Unep, 2009). People T&C is a consulting and training company based the core business in the values of social enterprise. The direct customers are all those who are interested in promoting organizational models based on cooperative culture and social responsibility. This work aims to define the Stakeholder Categories and Sub-categories for the social business through a case study application in People T&C. The results will be useful for the preparation of an effective business model and strategic business plan aimed at developing the company's core activities based on training and consulting services. After a literature review, a preliminary survey based of questionnaire to the internal stakeholders was constructed and conducted. The analysis was repeated for all stakeholders' categories, defined for each of the impact categories and, through network analysis support, we obtained the stakeholder map and their relationships. This stakeholder categories characterization helps to conduct the S-LCA analysis and contribute for a generalized model for similar companies.

451
Resilience, Society, and Sustainability through Equity
C. Stahl, U.S. Environmental Protection Agency / Region 9; R.J. McCormick, U.S. Department of the Interior Bureau of Land Management
From physics we know that achieving absolute sustainability for any society on Earth is not possible; there will always be material losses (waste) and energy transformations (increased entropy, degraded exergy), so by definition fossil fuel-based societies are not sustainable. But, we can always consider sustainability as a goal, however thermodynamically unreachable. Thus, any society can have the objective of achieving a level of resilience such that the planet doesn't mind their use of its ecological goods and services: a state of nominal if not absolute sustainability, and close enough to the goal. So the objective, the focus, of human societies is resilience. Not engineering resilience – the type of 'we will rebuild' resilience that increases GDP but does not solve the underlying reason for having to rebuild once, twice, thrice, perpetually. No, the type of resilience a society should strive for is ecological – that is, unremarkable, responsive, flexible, adaptive. Unremarkable in that it just happens, there is no call for meetings, no need for banner headlines. Responsive in that as occurs a change in the rate of ecological goods and services entering a social system from its supporting landscape, there occurs a timely and equivalent change in the rate of demand and use of those goods and services by society. Flexible in that as ecosystem changes occur there are no societal losers nor societal winners as a result – social systems provide for individuals and groups and industries and cities when the provision of ecological goods and services is altered. And more particularly, adaptive in that as humans occupying a landscape are presented with novel rates and volumes of provisions from a once-stable ecosystem, including the total loss of one or many goods or services, social changes and economic reorganizations occur with minimal turmoil and a new social-ecological system emerges. We will have focus on responsive, flexible and adaptive societies, communities, and tribes, with a focus on their sustainability narrative (from the four questions: what; for whom; how long; at what cost) and their perspectives on the use of science in social – ecological systems.

Organic Micropollutants in Urban Waters (II)

452
Enhancing the removal of emerging micropollutants through a biological wastewater treatment at low temperatures
A. Kruglova, Aalto University / Department of Built Environment; A. Mikola, Aalto University / Department of Civil and Environmental Engineering; A. Gonzalez-Martinez, University of Granada / Institute of Water Research; R. Vahala, Aalto University / BiologyCivil and Environmental Engineering
Growing concentrations of emerging micropollutants (EMs) such as over-the-counter drugs, hormones and antibiotics in the environment has recently bacome a global public health issue. Many of these substances are able to pass through all the treatment steps of common municipal wastewater treatment plants (WWTPs). Consequently, these pollutants have been detected in micro-concentrations in the environmental waters all over the world. The toxic effects on the aquatic organisms, spreading antibiotic resistance and accumulation due to constant consumption of these substances are calling for the new treatment solutions. In this study, the removal rates of widely-used EMs ibuprofen, diclofenac, carbamazepine, estrone, 17β-estradiol, 17α-ethynylestradiol were studied at common process temperatures for Nordic countries (8-12°C). Data obtained from full-scale processes were compared with the results from pilot Sequencing batch reactors and Membrane Bioreactors. Different operational conditions and dynamics of microbial communities of activated sludge were studied in order to find the preferable strategy for EMs removal in cold regions. In addition, the effect of environmental concentration of antibiotics sulfadiazine and trimethoprim on activated sludge performance was studied. The results showed surprisingly lower removal rates compared to the most of the data from other countries. The main suggested reason is the strong limiting effect of low temperatures on bacteria and other microorganisms, which are commonly used in treating municipal wastewaters. Additionally, studies of activated sludge solid phase demonstrated that EMs might accumulate in bacterial cells to a large extent. Furthermore, activated sludge microbial communities were unexpectedly different from common activated sludge communities reported which affected vulnerability of microorganisms to environmental concentrations of EMs especially, antibiotics. At the same time, the research showed, that optimization of the existing treatment technologies can significantly improve the removal of several studied substances and reduce negative effects of EMs on activated sludge key microorganisms. Additionally, process configurations may affect the growth of low-temperature adapted microorganisms. Overall, the study proves that low-temperature conditions should be considered as an important parameter in modern wastewater treatment plant design.

Biodegradation of pharmaceuticals in post-treatment moving bed biofilm reactor (MBBR): enantioselectivity and controlled co-degradation

C. Liang, Aarhus University; L. Zhang, Aarhus University / Department of Bioscience; N.B. Nord, Aarhus University Department of Environmental Science; P. Carvalho, Aarhus University, Department of Environmental Science / Department of Environmental Science; K. Bester, Aarhus University / Environmental Science

Moving bed biofilm reactors (MBBR) have been suggested to remove pharmaceuticals from wastewater, as a post-treatment. To overcome the scarcity of biodegradable carbon in wastewater effluents (post-treatment), a range of acetate (0-320 mg C/L) was dosed into MBBR to study the effects of acetate on biodegradation of 26 pharmaceuticals (β-blockers, analgesics, antidepressants, antibiotics and contrast media) at wastewater relevant concentrations. Reaction kinetics and enantiomeric fractions were analyzed. The results showed that all tested β-blockers and one metabolite (metoprolol acid) were degraded enantioselectively, and the enrichment of *S*- or first eluted enantiomer was observed. However, non-enantioselective degradation dominated until the majority of β-blockers was degraded, and enantiomer fractions started to change successively. This suggested the biodegradation of β-blockers was performed by both enantioselective and non-enantioselective enzymes. In the end of reaction, high doses (90-320 mg C/L) of acetate lowered the enantiomeric enrichment of atenolol, metoprolol, propranolol and metoprolol acid compared with the one with low doses of acetate, which indicated that the additional substrates like acetate could make a difference on the enantioselective biodegradation. On the other hand, the impacts of acetate on the degradation kinetics of pharmaceuticals were dose- and compound-dependent. While the removal of venlafaxine, tramadol and ciprofloxacin were promoted by dosed acetate, dosing acetate (especially with high dosage) inhibited the degradation of acetyl-sulfadiazine, ibuprofen, citalopram and diclofenac probably due to different mechanisms. Degradation of seventeen out of twenty-five tested compounds were found to be uninfluenced by the acetate dosage. These findings do not only provide evidence on dosing additional acetate cannot up-regulate removal of pharmaceuticals in post-treatment MBBR, but also help to understand relationships between easily degradable carbon source and the key biodegradation processes of pharmaceuticals.

454

Biological transformation of fexofenadine and sitagliptin by carrier attached biomass and suspended sludge

N. Henning, Federal Institute of Hydrology / G2 - Water Chemistry; A. Wick, Federal Institute of Hydrology; T. Ternes, Bundesanstalt für Gewaesserkunde

Biofilm reactors are used since the early 2000s to improve nutrient management, e.g. nitrification and denitrification, at full-scale wastewater treatment plants (WWTPs). It is assumed that the carrier attached biomass in moving bed biofilm reactors (MBBR) is much more effective in removing organic micropollutants from wastewater compared to activated sludge treatment. However, the formation of transformation products (TPs) in MBBRs, which are likely to occur, is not yet well reported. In this study the antidiabetic agent sitagliptin (STG) and the antihistaminic drug fexofenadine (FXF) were investigated concerning their behavior either in contact with suspended sludge or carrier attached biomass. Therefore, aerated batch experiments containing suspended sludge or carriers (both diluted with WWTP effluent) from a bench-scale MBBR were conducted. STG is almost completely degraded in both systems within 3 days (d). In contrast, FXF is removed much faster in contact with carriers (96% removal after 3 d) compared to suspended sludge (80% removal within 7 d). However, it can be assumed that the degradation of FXF and STG is biologically induced, as the concentration of both compounds remains stable in autoclaved carrier systems. In total, 11 TPs (7 TPs for STG and 4 TPs for FXF) were observed and chemical structures were proposed via high-resolution mass spectrometry (LC-QToF-MS). The structures of 3 TPs of STG and 2 TPs of FXF were unambiguously confirmed with available reference standards. Major transformation reactions consisted of dehydrogenation, amide cleavage or N-acylation. The formation of one major TP of STG was slightly higher in systems containing suspended sludge (reaching 55% (carrier) and 73% (sludge) of the initial STG concentration within 3 d). In contrast, the increase of one major TP of FXF was much faster in contact with carriers (57% (carriers) after 1 d compared to 58% (sludge) of initial FXF concentration after 7 d). Additionally, the TP is further degraded during the following incubation, which cannot be observed in systems with suspended sludge. This supports that carrier attached biofilms of MBBRs can improve the transformation of certain micropollutants as well as their primary TPs. Current investigations focus on the quantification of the identified TPs, in order to investigate i) their fate in advanced wastewater treatment technologies (e.g. ozonation) and ii) their relevance for the aquatic environment.

455

Removal of organic micropollutants and nanoparticles in pilot scale ultrafiltration and GAC-filtration

E. Edefell, Sweden Water Research; O. Svahn, Kristianstad University; O. Modin, Chalmers University of Technology; M. Cimbritz, LTH Lund University / Department of Chemical Engineering

Municipal wastewater treatment plants, WWTPs, realeases organic micropollutants and nanoparticles to the environment. Treatment plants today can seldom control the emissions of these compounds. Upgrading WWTPs with advanced treatment methods reduces emissions and increases the possibilities to reuse water. This study aims at investigating the potential of ultrafiltration (UF) and granular activeted carbon (GAC) filtration in long-term (one year) pilot experiments treating effluent wastewater, as well as tracking organic micropollutants through a conventional WWTP. Organic micropollutants were measured with UHPLC-ESI-MS/MS. Nanoparticles were analysed before and after the pilot using Nanoparticle Tracking Analysis (NTA). The emissions of organic micropollutants and nanoparticles from the WWTP were substantially reduced with UF and GAC for the duration of the study. The ultrafiltration showed a minimum of 2.5 log reduction of nanoparticles, the effluent concentration was below the quantification limit. Organic micropollutants was predominantly removed through adsorption to the activated carbon. Eighteen of the 23 analysed compounds showed a removal efficiency higher than 95% during the first 10 000 BV. Further through the study, a majority of the compounds were removed to more than 80% throughout the experimental period, 18 000 BV, e.g. carbamazepine, tramadol, the hormone estrone and the antibiotics clarithromycin, erythromycin and trimethoprim. The antianxiety drug oxazepam, the antidepressant drug venlafaxine and the painkillers diclofenac, ibuprofen and naproxen showed a slightly lower removal (75%) be the end of the study. While most of the micropollutants were removed to a high degree throughout the study, the removal of a few compounds such as sulfamethoxazole, PFOS and flukonazol decreased substantially over time (5-56%). The study was also tracking the organic micropollutants through the WWTP with biological and chemical treatment. A few compounds were removed to more than 80% in the conventional treatment; ibuprofen, naproxen, estrone and sulfamethoxazole. All other measured compounds showed a removal of less than 25%. The emissions of organic micropollutants via municipal wastewater can be efficiently reduced through GAC-filtration. In addition, microorganisms and nanoparticles can be removed with UF. Both techniques are viable alternatives for full-scale implementations.

456

Effect of ozone dose on the formation and removal of transformation products of pharmaceuticals during ozonation of secondary effluent

S. KHAREL, Aarhus University / Environmental Science; M. Stapf, U. Miehe, Kompetenzzentrum Wasser Berlin gGmbH; K. Bester, Aarhus University / Environmental Science

Removal of organic micropollutants (e.g. pharmaceuticals) in wastewater treatment plant requires advanced treatment technologies like ozonation, activated carbon, membrane bioreactor, etc. Among several techniques, ozonation has gained popularity due to its competence to remove wide range of micropollutants also in relatively short time. However, the removal process does not simply mineralize the micropollutants rather it transforms them to other compounds. These transformation products might have adverse effects on the aquatic ecosystem and necessitate further research. Consequently, the formation of the transformation products (TPs) were quantified in dependence of the specific ozone dose in a pilot plant which was operated poststream of an activated sludge wastewater treatment plant. Samples were analyzed to quantify 17 different TPs along with various water quality parameters. Those TPs that are formed by human metabolism were removed in dependence with the specific ozone dose (mg O_3 / mg DOC). However, the typical ozonation products i.e. Venlafaxine N-oxide and Tramadol N-oxide are formed during ozonation with increasing ozone dose. The formation occurs at relative low specific ozone dose (typically around 0.5 mg O_3 / mg DOC). However, most of these ozonation products are removed again at higher specific ozone dose (typically > 0.8 mg O_3 / mg DOC).

457

Removal of organic micropollutants by activated carbon - gaining mechanistic insights by thermogravimetric analysis

D. Dittmann, Bundesanstalt für Materialforschung und -prüfung; A.S. Ruhl, Technische Universität Berlin / Chair of Water Quality Control; M. Jekel, Technische Universität Berlin; U. Braun, BAM- Federal Institute Materials Research and Testing / 5.3 Mechanics of Polymers

Advanced wastewater treatment by the application of activated carbon is used to eliminate organic micropollutants in large scale wastewater treatment plants. However, underlying adsorption processes are unclear. On the one hand, compositions of wastewater differ and are very complex. On the other hand, activated carbons have physicochemical properties which impair investigations on adsorption mechanisms, since they are non-graphitic, non-graphitizable and have a highly disordered microstructure. This leads to their large surface areas and internal pore structure but also implies heteroatoms and functional groups. These are not easily accessible for research but affect the adsorption of organic micropollutants. Thermogravimetric analysis and evolved gas analysis can provide valuable insights into these kinds of systems. First, pyrolysis makes functional surface groups accessible, e.g. through decarboxylation, which facilitates characterisation of activated carbons. Second, adsorbates can be investigated by thermal desorption or decomposition, depending on the sorption conditions of the organic micropollutants. Single component systems as well as multi component systems with competing organic background matter are compared for various activated carbons. Surprising distinctions in the adsorption mechanisms will be presented.

The Fate, Effects, and Mitigation of Oil Spills on Aquatic and Marine Environments

458
Responses of freshwater vertebrates and their food web to experimental spills of diluted bitumen
D.M. Orihel, Queens University / Department of Biology/School of Environmental Studies; M.L. Hanson, University of Manitoba / Department of Environment and Geography; B.P. Hollebone, Environment and Climate Change Canada; V. Palace, IISD-Experimental Lakes Area; J. Luis Rodriguez Gil, University of Ottawa; V.S. Langlois, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; L. Baillon, National de la Recherche Scientifique; T. Black, University of Manitoba / Department of Environment & Geography; J. Cederwall, Queens University / Biology; D. Denton, University of Winnipeg; C.W. Greer, National Research Council of Canada; C. Hasler, University of Winnipeg; L. Lara-Jacobo, Institut National de la Recherche Scientifique / Centre Eau Terre Environnement; D. Layton Matthews, Queens University / Geology; M. Leybourne, J.J. Mason, Queens University; C. Maynard, National Research Council of Canada; A.C. Ortmann, Fisheries and Oceans Canada; M. Paterson, IISD-Experimental Lakes Area; S.A. Patterson, Queens University / School of Environmental Studies; B. Pauli, Environment and Climate Change Canada / National Wildlife Research Centre; R.C. Rooney, University of Waterloo; S.S. Stoyanovich, University of Ottawa; L. Timlick, University of Manitoba; J.M. Blais, University of Ottawa / Department of Biology
Oil spills in inland waters may be infrequent, but their consequences on ecologically sensitive ecosystems could be profound and require further study. As part of the BOREAL (Boreal lake Oil Release Experiment by Additions to Limnocorrals) study, we conducted a series of oil spill simulation experiments at the IISD-Experimental Lakes Area, a unique freshwater research facility situated in Ontario, Canada. A pilot study was performed in 2017 over 12 days using three microcosms (2-m diameter) floated in land-based tanks, and an in-lake study was performed in 2018 over 100 days using nine limnocorrals installed in the littoral zone of an oligotrophic boreal lake. Diluted bitumen, a viscous unconventional oil product commonly transported in Canada, was used for both experiments. The specific objectives of this paper were (i) to assess the responses of different levels of the lower food web, including bacteria, phytoplankton, and zooplankton, to experimental dilbit spills; and (ii) to examine the toxicity of lake water contaminated by experimental dilbit spills to three freshwater vertebrates. We used a multifaceted approach with numerous traditional and advanced techniques to examine changes in the biomass, species composition, and diversity of prokaryotes and eukaryotes in response to a comprehensive range of dilbit spill scenarios. To evaluate toxicity of naturally weathered dilbit, we exposed fathead minnows, finescale dace, and wood frogs to lakewater contaminated by dilbit spills collected from the limnocorrals and assessed survival and a suite of sublethal endpoints including growth, development, and behaviour. Based on a pilot study performed in aquatic microcosms containing natural lake water and sediment, we conclude that, at least in the short-term, dilbit spills appear to alter the abundance, diversity, and composition of planktonic communities. Data from our in-lake study will provide important insights regarding the chronic effects of dilbit on littoral communities of boreal lakes, as well as the toxicity of naturally weathered dilbit on fish and amphibians. Preliminary data suggest a concentration-response increase in the rate of malformations for fathead minnow larvae with dilbit weathering. We anticipate this research will improve the design of sampling programs to monitor impacts and recovery of dilbit spills into inland waters from pipeline ruptures and train accidents.

459
Effects of the water accommodated fraction of North Sea crude oil on Calanus finmarchicus
T. Ciesielski, Norwegian University of Science and Technology / Biology; S. Soloperto, NTNU University; E.A. Cichosz, NTNU The Norwegian University of Science and Technology; D. Altin, BioTrix; A. Hallmann, Medical University of Gdansk / Department of Pharmaceutical Biochemistry; E. Skottene, Norwegian University of Science and Technology; T. Størseth, B. Hansen, SINTEF Ocean / Environment and New Resources; B. Jenssen, Norwegian University of Science and Technology / Biology
Calanus finmarchicus is an ecologically important species in the North Atlantic. Due to continued development of areas for oil and gas production, as well as increase shipping, there are both continuous and accidental environmental discharges of petroleum oil in this region. The present study aimed at investigating oxidative stress, lipid peroxidation and protein damage biomarkers and changes in metabolome profile in *C. finmarchicus* exposed to a water accommodated fraction (WAF) of a naphthenic crude oil from the North Sea (NS). Non-ovulating adult females (n=5580) of *C. finmarchicus* from a continuous lab were used in exposure studies with WAF of a naphthenic NS crude oil. Individuals were exposed to a sub-lethal concentration of WAF corresponding to the 50% of the 96h LC_{50} and were sampled at 0, 24, 48, 72 and 96 hours. Standard analyses for semi-volatile (SVOC) and volatile organic compounds (VOC) in crude oil and WAF were performed with GC-MS and purge and trap GC-MS, respectively. Biomarkers of oxidative stress, lipid peroxidation and protein damage were determined using qPCR, enzymatic activities analysis and oxidative stress-related molecules malondialdehyde (MDA) and glutathione were analysed by colorimetry and UV-VIS spectrophotometry. Untargeted metabolomics using proton nuclear magnetic resonance (^{1}H NMR) spectroscopy was applied for studing effects of exposure on metabolome profile. Significant induction of glutathione S-transferases and increase of MDA concentrations in the exposed group indicates that both biomarkers are usefull indicators of oxidative stress in copepods exposed to NS crude oil WAF. In addition, the results suggest that lipid peroxidation is a main toxic endpoint in the exposed animals. In contrast, gene expression results showed inconsistent responses with both up- and downregulation. The concentrations of many metabolites (mostly amino acids), were significantly lower in the WAF exposed animals than in the control animals. Similary, the organic acid malonate concentration decreased during the experiment in control animals, but increased in the WAF exposed animals. These changes could be explained by the combined effects of oil and starvation. Metabolome changes suggest that exposure to WAF might impair energy balance in *C. finmarchicus* and malonate seems to be a promising biomarker of oil exposure. Field studies are needed to confirm and test the proposed biomarkes and metabolome changes in real scenerio of oil spil.

Using transcriptional responses in zebrafish embryos to characterize biomarkers for crude and dispersed oil toxicity
S. Johann, Institute for Environmental Research RWTH Aachen University; L. Nuesser, RWTH Aachen University, Institute for Environmental Research / Department of Ecosystem Analysis; B. Denecke, A. Abdallah, Interdisciplinary Centre for Clinical Research, Medical Faculty, RWTH Aachen University; H. Hollert, RWTH Aachen University / Institute for Environmental Research; T. Seiler, RWTH Aachen University / Ecosystem Analysis
In this study zebrafish embryos were exposed to a naphthenic North Sea crude oil characterized by a high proportion of low molecular weight saturates and aromatics. A third generation dispersant that can be used as a chemical response action to combat oil spills was integrated. Especially during the embryonic development aqueous compounds of crude oils lead to adverse effects at low concentrations. Of major interest is the underlying molecular pathway for the affected biological functions. The results from whole transcriptome analysis provide an initial understanding of the underlying processes leading to the disruption of biological functions and can be used to focus subsequent studies using mechanism-specific bioassays. Zebrafish eggs were exposed shortly after fertilization to selected concentrations (EC_{10}) of low energy water-accommodated fractions (LEWAF) and chemically enhanced water-accommodated fractions (CEWAF). Embryos were incubated at 26°C with daily medium exchange. At 119 hours post fertilization the exposure was terminated. To investigate larval swimming behaviour a light/dark transition test was conducted using a DanioVision observation chamber and EthoVision tracking software (Noldus, Netherlands). For the RNA sequencing the Illumina NextSeq 500 was used. The cut-off value for regulation of genes used for functional annotation analysis was set to 1.5 fold greater or lesser compared to the control. The statistical analysis of expression in mRNA levels between control and treatment groups found significantly different (p value = 0.01) expression of 2223 genes for LEWAF and 4048 genes for CEWAF exposure, respectively. Among the most regulated genes in both treatment groups were genes that belong to the phase 1 metabolism. Furthermore, the analysis showed that multiple genes associated with the development of the eye and genes associated with phototransduction were regulated. Interestingly, exposed embryos showed significantly reduced swimming activity compared to control fish in dark stimulus conditions of the behavior assay. The exposure to LEWAF and CEWAF led to significant changes in expression of genes that are associated with the regulation of the circadian clock in the embryos. Hence, the present study allows the confirmation of known affected pathways that had been described for other species after exposure to crude oils but also novel pathways for crude oil mediated toxicity like the alteration of the circadian rhythm might be derived

For reliable mussel monitoring programs based on biomarkers, relevant baseline values and their natural variability need to be known. The Baltic Sea exhibits high inter-regional and seasonal variability in physical factors. In this study, mussels were collected from reference sites in Kiel (Germany) and Tvärminne (Finland) in three different seasons: summer and autumn 2016, and spring 2017. At biochemical level catalase, glutathione-S-transferase activities and lipid peroxidation in digestive gland and acetylcholinesterase activity in gills were measured. At cellular level changes in lysosomal membrane stability, lysosomal structural changes, lipofuscin and neutral lipid accumulation were selected. Changes in cell type composition in digestive alveoli, alterations in the digestive gland and changes in adipogranular cell density were examined to determine the responses at tissue-level. Histopathological alterations were examined in digestive gland, gonad and gills. Gamete developmental index was also determined. To characterize the ecological situation that was conditioning the biomarkers measured, analysis of the chemical tissue burden was performed and Chlorophyll-a and particulate organic carbon concentration and temperature changes were analyzed in each sampling locality using satellite remote sensing. In addition, an integrated biological responses index was performed to summarize the biomarker responses of each locality and season. Biochemical endpoints showed higher seasonal variability conditioned by temperature, food supply and reproductive cycle, while among the cellular endpoints, lipofuscin accumulation and lysosomal structural changes showed some kind of seasonal variation. Regarding tissue level biomarkers, only in Tvärminne seasonal changes were found, which were dictated by the more demanding energetic trade-off caused by reproduction. Histopathological analysis revealed differences between both sampling sites. It can be concluded that the ecological variables in each sampling site and season influenced the measured biomarkers in different ways, thus, to perform a correct assessment of the biological effect of a hypothetical pollution scenario in the Baltic Sea, biomarker baseline values and their response to environmental conditions must investigated in different localities and seasons. *Acknowledgement* - Funded by EU GRACE Project (nº 679266), CGL2016-76561-R (MINECO). The effects of the Deep Water Horizon oil spill on marine microalgae - A comparison of species sensitivity
K. Softcheck, Smithers Viscient, LLC / Ecotoxicology; J. McGrath, Exponent Inc. / EcoSciences; M.T. BenKinney, Exponent; R.C. Biever, Smithers Viscient, LLC / Department of Ecotoxicology
Limited algal toxicity data have been generated with crude or weathered oils as part of oil spill response and environmental impact assessment activities. Smithers Viscient conducted a series of toxicity tests using four standard microalgae species: *Dunaliella tertiolecta*, *Skeletonema costatum*, *Isochrysis galbana*, and *Thalassiosira pseudonana*, and one macroalga: *Ectocarpus siliculosus*. Eight toxicity tests for *Dunaliella* and *Skeletonema*, and four each for *Isochrysis*, *Thalassiosira*, and *Ectocarpus* were conducted with field-collected source and weathered oil samples collected during the Deepwater Horizon (DWH) MC252 Spill of U.S. National Significance. The subset of the data was evaluated to compare the species sensitivity of two of the algae tested, *Skeletonema costatum* and *Isochrysis galbana* for one of the weathered oil samples collected from the Gulf of Mexico during the DWH oil spill event. As crude oils are mixtures of poorly water-soluble hydrocarbons, exposures of weathered oil water-accommodated fractions (WAFs) were conducted at nominal loading concentrations of 100, 50, 25, 13, and 6.3% of a 1000 mg/L or 1.0 mL/L(oil) solution. Exposure solution samples were collected at the beginning and end of each exposure period for detailed chemical analysis of oil composition: volatile organic compounds (VOCs), parent and alkylated polycyclic aromatic hydrocarbons (PAHs), saturated hydrocarbon compounds (SHCs), and total petroleum hydrocarbons (TPH) or total extractable materials (TEM) concentrations. Oil toxicity was determined based on average specific growth rates and No-Observed Effect Concentration (NOEC) values. Results were also expressed based on the nominal loading percent WAF based on the dissolved sum of toxic unit (ΣTUs) of the whole oil. The data were compared to evaluate if the Target Lipid Model (TLM) is protective of algae based on the data for these species.

The iCASS Platform: Nine principles for landscape conservation design
R.J. McCormick, U.S. Department of the Interior Bureau of Land Management
The Anthropocene presents society with a super wicked problem comprised of multiple contingent and conflicting issues driven by a complex array of change agents. Super wicked problems cannot be addressed using siloed decision-making approaches developed by hierarchical institutions using science that is compartmentalized by discipline, nor can they be managed under the assumption that environmental conditions are stable. Adaptive solutions rest on human ingenuity that fosters transformation towards sustainability. To successfully achieve these objectives, conservation and natural resource practitioners need a paradigm that transcends single-institution interests and decision-making processes. Landscape ecologists link spatial patterns and processes to yield astute conservation recommendations. In practice, however, many of the recommendations that are informed by interdisciplinary science are not implemented. How can sustainability practitioners overcome this wicked problem? An oft-cited solution is to situate landscape ecology findings within a broader framework designed for achieving implementation. Increasing the knowledge base around this strategy is a current area of conservation innovation. We will present an innovation systems framework for an emerging and evolutionary step change in integrating landscape ecology into sustainability planning: landscape conservation design (LCD). We use existing governance and adaptation planning principles to develop an iterative, flexible framework—the "iCASS Platform." It consists of nine principles within five primary attributes—**i**nnovation, **c**onvening stakeholders, **a**ssessing current and plausible future landscape conditions, **s**patial design, and **s**trategy design. The iCASS Platform can facilitate LCD via processes that aim to create and empower social networks, foster stakeholder involvement, engender co-production and cross-pollination of knowledge, and provide multiple opportunities for deliberation, transparency, and collaborative decision-making. Our intention is to inspire a pivot from single-institution, siloed assessment and planning to stakeholder-driven, participatory design, leading to collaborative decision-making and extensive landscape conservation.

The experience of two European projects on how to combine social, environmental, and economic values in mining
C. Di Noi, A. Ciroth, GreenDelta GmbH; M. Räikkönen, VTT Technical Research Centre of Finland Ltd; S. Horn, Outotec; R. Molarius, VTT Technical Research Centre of Finland Ltd
Mining is usually a multifaceted topic due to complex and sometimes conflicting relations between different parties involved in the value ecosystem. The present work reports on how the challenges related to social, environmental, and economic sustainability in mining have been addressed by two European projects, namely ITERAMS, funded by the European Union H2020 programme, and SERENE, funded by the European Institute of Innovation and Technology. The purpose of this work is to explore the approach (and related challenges) aimed at identifying the different values generated by the mining projects and how these values may be combined and achieved both with the reduction of negative issues and risks and with the generation of positive impacts. The approach is based on mapping the stakeholders affected by the novel mining solutions foreseen by ITERAMS and SERENE, investigating the values potentially generated by the two projects for the different sustainability dimensions, and defining the related pressures and risks. Different tools and methods are used to perform the described approach, including literature research, a qualitative causal loop modelling, a social analysis, interviews with key stakeholders, and a preliminary Life Cycle Assessment (LCA) and Life Cycle Costing (LCC) screening, followed by a full LCA, LCC and risk assessment evaluation. According to the focus of the projects, several water related values can be highlighted, such as water quality, availability, and management together with land preservation, health and safety, trust, respect of the regulatory standards, and monitoring of the system. The topics first identified at a general level are then characterized for the project validation sites in Finland, Portugal, and South Africa. This characterization is based on the definition of background situations which can affect the values, risks, and pressures. It is worth noticing that the meaning of the values identified may be different from one location to another because the risks and pressures which interact with these values are strictly dependent on the local environmental, social, socio-economic, cultural, and political context. The present contribution moves in the direction where balancing social, environmental, and economic issues does not mean that impacts can be shifted or compensated by another sustainability dimension, but rather the performance should be equally good and acceptable for all the stakeholders and topics involved.

Precautionary risk assessment scheme for deep-sea mining

V. Nogueira, Faculty of Sciences and CIIMAR - Porto University; M.M. Santos, CIIMAR/FCUP / Biology/Endocrine Disruptors and Emerging Contaminants; F. Castro, CIIMAR University of Porto; R. Pereira, GreenUPorto & Faculty of Sciences, University of Porto / Dept Biology Faculty of Sciences of the University of Porto

The land-based deposits are depleting and the demand for metals is still increasing, giving rise to a growing interest in the exploration of mineral resources from the deep-sea. The International Seabed Authority has already given out 29 exploration contracts, whether for polymetallic nodules, cobalt-rich crusts or seafloor massive sulfides, and although until now the main focus was the exploration of the deep, the exploitation may soon begin. However, these resources cannot be considered in isolation since they are part of unique and most of the cases poorly understood ecosystems, such as hydrothermal vents. This has raised several concerns by the scientific community due to the possible, and probably irrecoverable, environmental impacts of the mining operations both, at the seafloor and along the water column till the surface, caused by the formation and dispersion of plumes, the movement of heavy machinery and the continues exposure to noise and light, in an environment where life evolved in the darkness. Such impacts will include within other aspects the loss of biodiversity, changes on organic matter degradation and nutrients cycling (nitrogen, phosphorus, silica, sulphur, and hydrogen), with subsequent loss of important ecosystem services. Taking this into account, lessons have to learned from the impacts on the mining activity on land, and precautionary measures should be taken to minimize negative environmental impacts before the exploitation phase.Hence, based upon currently available information and the precautionary principle approach we aim to propose a preliminary risk assessment framework to be applied during the prospection phase to support decision making before explotation contracts are granted.

Challenges for the pesticide regulation in the EU: A German perspective

A. Gathmann, Federal Office of Consumer Protection and Food Safety / Plant Protection Products

Pesticide regulation of plant protection products (PPP) is an increasing complex process in Europe. Demands on the application are laid down in the legal framework and several guidance documents. However country specific approaches in risk assessment and risk mitigation increase the complexity of the authorization process. In some areas this complexity has the potential to result in a lack of harmonization for both risk assessment and risk management. Furthermore technical developments, state of science and technology in risk assessment and risk management, active substances with new mode of action such as RNAi based PPP, societal and political demands on agriculture production systems and as a consequence operationalisation of protection goals additionally challenge applicants, risk assessors, risk managers and decision makers. The presentation will highlight some of the most relevant challenges for the authorization of plant protection products from the perspective of the German competent authority. The current situation and critical aspects will be described and identified. For some aspects some first thoughts and ideas will be presented which might show the way forward to improve the authorization process of pesticide regulation.

Protection goals for non-target terrestrial plants: Can precision application technology help ?

J. Davies, Syngenta / Environmental Safety; P. Sutton, Syngenta

EFSA's Scientific Opinion addressing the state of the science on the risk assessment of plant protection products for non-target terrestrial plants (NTTPs) was published in 2014. The Opinion defines non-target plants as all plants growing outside fields and those growing within fields that are not the intended pesticide target. It also states that non-crop plants growing in in-field areas provide ecosystem services including food web support, aesthetic value, genetic resources and endangered species, which require protection from the adverse effects of plant protection products. Since 2014, options for protecting ecosystem services provided by non-crop plants have been discussed in various stakeholder workshops. However, the regulatory debates around these issues rarely consider advances in agricultural technology (i.e. precision agriculture techniques) that have the potential to modify the way in which herbicides are applied in the future and will minimize the risks perceived to be associated with their use. Increasing precision enablement of crop sprayers includes the use of GPS systems, boom section control and pressure variation, so enabling variable applications across fields. Meanwhile, increased understanding of the environmental factors driving target weed distributions allows development of field-specific weed maps. Combination of these approaches will enable patch spraying whereby only the infested area of a field is treated. Estimates suggest that these approaches will permit a 6 to 81% reduction in the use of herbicides selective for broad-leaved weeds and a 20-79% reduction for products selective for grass weeds while use of automatic boom section control has been found to reduce use by 15.2 to 17.5% when compared with no boom section control[(1)]. This presentation aims to raise awareness of the potential environmental benefits of the use of precision technologies for weed control. If European agriculture is to benefit from these innovations in the future, the EU needs to retain access (i.e. registrations) to the necessary herbicide products by developing regulatory risk assessment processes that accommodate the use of these technologies. Food security and functioning ecosystems: the role of ecosystem services in framing protection goals

L. Maltby, The University of Sheffield / Dpt. of Animal & Plant Sciences

Ecosystems and the biodiversity they support are essential to human survival, health and well-being. Ecosystem services are provided by landscape elements and hence an ecosystem services approach to environmental protection is inherently linked to how we manage landscapes. Half the habitable land in the world is managed by farmers and continuing growth in the human population will mean that the global demand for food will increase for at least another 40 years. People need both food security and functioning ecosystems. We therefore need to manage landscapes to optimise food production and other ecosystem services. However, because of trade-offs between yield, agricultural area and biodiversity, we can't have everything, everywhere, all of the time. An ecosystem services approach is one way to frame protection goals and help identify some of the trade-offs to be factored into land management decisions, including the use of chemicals. An ecosystem, services approach could result in better informed risk management decisions and more relevant environmental risk assessment by focusing protection goals on what stakeholders value. It increases transparency in trade-offs and prioritisation of ecosystem services (i.e. what to protect where and why) and offers the potential of a more holistic approach to environmental management. Ecosystems have the potential to provide many ecosystem services and adopting an ecosystem services approach requires greater ecological understanding, which may be a challenge for implementation. There is an urgent need to develop tools that either measure ecosystem services directly or produce information that can be robustly extrapolated to ecosystem service performance. Crop production systems are part of the wider landscape and are influenced by social, economic and policy drivers. Any reduction in the amount or type of food produced in Europe may result in unintended consequences on global biodiversity. This is because displacing food production also displaces environmental impact, often to areas with greater biodiversity value and weaker environmental controls than in Europe. We therefore need to take a holistic, systems-based approach to managing food production for the benefit of people and nature.

Human Health and Environmental Risk Assessment of Chemical Mixtures: Moving Towards the Non-toxic Environment (II)

470

From words to action - How can chemicals legislation be improved to deal with groups of chemicals and take cumulative exposures and mixture toxicity into account?

C. Rudén, Stockholm University, ACES / Department of Environmental Science and Analytical Chemistry ACES; T. Backhaus, University of Gothenburg / Department of Biology and Environmental Sciences; P. Bergman, Privatperson; M. Faust, Faust & Backhaus Environmental Consulting; L. Molander, Folkhalsomyndigheten; D. Slunge, gothenburg university

The need to develop regulatory strategies for assessing cumulative exposures and mixture toxicity has been pointed out in several policy documents on the EU level and in Sweden. Currently the pesticide and biocide legislations specifically require a cumulative risk assessment, and guidance for such assessments are available. However, regulatory approaches need to be developed also for other types of chemicals. Addressing mixtures increases the complexity of risk assessment and data demands, and grouping of chemicals might help structuring this complexity. Grouping might also facilitate read-across and help avoiding "bad substitution". To explore possible ways forward, the Swedish Government established a special inquiry. Here this inquiry will present its draft recommendations: 1. Single substances are regulated under different legislations and no agency or other authoritative body has the mandate to add up the exposures for the purpose of risk assessment. 2. The current risk assessment paradigm assumes that individual substances are released into an otherwise pristine environment. 3. There is no EU legislation that has the general scope and objective to ensure a good health status of humans, taking cumulative exposures to chemicals and mixture toxicity into account. 4. The effectiveness of chemicals risk management is undermined when a chemical with undesirable properties can be substituted with a chemical that has similar properties. 5. Monitoring can show unacceptable concentrations of chemicals in the environment or humans, but sufficiently effective feed-back loops to the rules controlling emissions are missing. 6. We lack information on real-life exposure patterns to mixtures, how exposures differ in time and space, and which chemicals drive mixture risks. 7. Authorities need resources to develop regulatory processes and practices that can make the implementation of chemicals legislation more efficient and up to date with current knowledge. For each of these issues an inventory of possible regulatory actions was compiled. The inventory includes proposals from the scientific literature and agency reports as well as input received during a number of stakeholder meetings. The resulting collection of proposals was combined with an analysis of the relevant EU legislations to identify concrete opportunities for improvement. The final recommendations will be presented to the Swedish Government by the 29th of September 2019.

471
Is mixture toxicity behaviour a devaluated tool in the formulation of Plant Protection Products meeting new regulatory requirements?
L. Queirós, University of Aveiro / department of Biology & CESAM; T. Vidal, University of Aveiro / Biology department; A.J. Nogueira, F.J. Gonçalves, J. Pereira, University of Aveiro / Department of Biology & CESAM
The production of eco-friendlier Plant Protection Products (PPPs) is a technical challenge and a regulatory requirement. The agrochemical industry has invested mainly in the reformulation of available PPPs to fulfill the regulation. However, during the developing stages of new formulations, the mixing of the ingredients has not been systematically tested, in order to identify effective combinations which may be less harmful to the environment. In this study, a commercial herbicide combining two active substances (a.s.), nicosulfuron and terbuthylazine, was used as model PPP. The a.s. were combined at different ratios to identify alternative formulations with reduced impacts in a non-target indicator (*Lemna minor*) representing potentially contaminated edge-of-field surface waters. Single and mixture toxicity tests with *L. minor* revealed that these a.s. act antagonistically towards the macrophyte, when combined. This suggests a protective effect of the combination compared to the a.s. dosed individually. The a.s. were also tested for efficacy, both singly and in mixture, towards a target weed for this commercial formulation, the weed *Portulaca Oleracea.* Likewise, the a.s. revealed an antagonistic behavior throughout the whole response surface. The study showed that (i) there were no environmentally safe a.s. combinations ensuring target-efficacy; (ii) terbuthylazine alone was effective in controlling *P. oleracea* with no environmental hazardous potential, dosed at concentrations 10-fold lower than those involved in commercially recommended application doses. Overall, this case-study suggests that modelling tools widely used in the field of environmental risk assessment of PPPs may also be useful in PPP design stages for a more efficient joint meeting of efficacy and environmental friendliness requirements.

472
Aquatic community responses as consequence of a realistic multiple low dose pesticide exposure scenario in stream mesocosms
R. Gergs, Umweltbundesamt; S. Mohr, German Environment Agency / IV; M. Feibicke, Umweltbundesamt; S. Meinecke, S. Duquesne, German Environment Agency; T. Frische, Federal Environment Agency (UBA) / Section Plant Protection Products; R. Schmidt, German Environment Agency
Usual agricultural practice is the application of a set of different types of plant protection products (PPPs) within a crop-specific spraying sequence during a season. Due to discharges aquatic communities inhabiting adjacent streams are consecutively exposed to a set of pesticides, which may cause a multiple-stress for non-target organisms. However, potential additive or even synergistic effects of realistic exposure scenarios are rarely investigated, especially on the community level. Here, we studied the effects of a pesticide spray sequence for apple cultivation on aquatic communities in surface waters using eight indoor stream mesocosms. Donated concentrations of the active substances were based on the specific regulatory acceptable concentrations (RAC) derived from the risk assessment of each PPP, a specific concentration considered as acceptable to occur in surface waters. We hypothesize that the exposition by a realistic spray sequence of pesticides using product-specific RACs has no effect on aquatic communities in stream mesocosms. Overall, nine fungicides, four insecticides and four herbicides at nineteen days were applied at their respective RACs for surface waters to each of the four treatment mesocosms within a period of more than 100 days. By lack of serious effects, a set of pronounced effects were monitored on structural and functional levels: benthic invertebrates and emerging merolimnic insects showed an effect on the community level at the end of the experiment indicating an effect of the multiple stress scenario event at the applied low concentration level (RAC). Furthermore, several single taxa showed a significant higher variability in the treatment mesocosms. Congruently, a reduced primary production in the macrophyte *Potamogeton natans* and a slower decrease in the potassium concentration in the water phase were measured over time indicating a bias between primary production and respiration processes at the community level. This study indicates the need to consider realistic multiple stress induced by PPP in crop-specific spraying sequence for the evaluation of potential effects on non-target organisms also on the long term and partly beside classical endpoints for mesocosm experiment. Thus it is still necessary to consider carefully if the overall level of protection intended by the legislative framwork (1107/2009/EC) are reached by the current practice of environmental risk assessment, i.e. for individual PPPs separately.

From individuals to populations: evaluation of laboratory-based predictions for toxicity of neonicotinoids and their mixtures to sensitive aquatic insects
E. Maloney, University of Saskatchewan / Toxicology; K. Liber, University of Saskatchewan / Toxicology Centre; K. Peru, J.V. Headley, Environment and Climate Change Canada / Watershed Hydrology and Ecology Research Division; C.A. Morrissey, University of Saskatchewan / Biology
Widely applied due to their favourable physicochemical characteristics (e.g. persistence, hydrophilicity), broad pest spectra, and versatility in use, neonicotinoids have become ubiquitous freshwater contaminants. Rather than single compounds, neonicotinoids are likely to be detected as mixtures, posing a risk to aquatic insects inhabiting contaminated environments. Recent laboratory studies have shown that neonicotinoid mixtures can elicit greater-than-additive toxicity in the aquatic insect, *Chironomus dilutus*. However, this has yet to be validated under field conditions. In this study, we characterized the chronic (28 and 56 d) toxicity of three compounds (imidacloprid (IMI), clothianidin (CLO), and thiamethoxam (TMX)) and their mixtures to natural insect communities. Using experimental *in situ* enclosures (limnocorrals), we exposed wetland insects to neonicotinoids/mixtures at theoretically equitoxic concentrations (1 toxic unit, Concentration Addition) and evaluated their toxicological effects on both the composition of all emerged insect taxa and cumulative Chironomidae emergence over time. Neonicotinoid treatment subtly shifted community composition, significantly increasing the relative proportions of emergent Trichoptera and Odonata in treated enclosures. Cumulative emergence increased over time in all limnocorrals, and there was a significant interaction between time and treatment. At 28 d (study midpoint), cumulative Chironomidae emergence was not significantly different between neonicotinoid treatments and controls. However, cumulative emergences in IMI, CLO, and CLO-TMX treatments were 42%, 20%, and 44% lower-than-predicted from applied doses. At 56 days (study cessation), effects on cumulative emergence became significant for these three treatments. However, due in part to high intra-treatment variation, mixtures were not more toxic than single compounds (after 28 or 56 d). Therefore, laboratory-derived predictions did not adequately account for neonicotinoid/mixture toxicity under field conditions. Observed greater-than-predicted single compound and concentration additive mixture toxicity should be accounted for in neonicotinoid-based environmental risk assessments and regulatory actions. This study indicates that single-species tests may not adequately predict the effects of neonicotinoids on sensitive aquatic insect populations, and, most importantly, demonstrates the need for field-validation of laboratory-derived toxicity predictions.

Exploring the Nano-Cosm: Advances in multi-element single-particle Analysis for Nanoparticle Characterization in the Environment
F. Von der Kammer, Vienna University / Department of Environmental Geosciences; M.D. Montaño, Western Washington University / Environmental Sciences; S. El Youbi, T. Hofmann, University of Vienna / Department of Environmental Geosciences
The advances in engineered nanotechnology lead to a commensurate development of sophisticated and sensitive analytical techniques capable of detecting and characterizing nanomaterials in complex environmental matrices. Though early single particle ICP-MS (spICP-MS) has demonstrated considerable promise in providing the size and number concentration of nanoparticles in very simple combinations of nanoparticles and environmental systems, it has been limited through its inability to accurately quantify more than a single element per particle, lacking compositional and identity information. The introduction of single-particle inductively coupled plasma time-of-flight mass spectrometry (spICP-TOF-MS) enables multi-element quantitation on a particle-by-particle basis, opening the door for both more accurate assessment of engineered nanoparticle exposure, and the exploration of geochemical processes at the nanoscale. By virtue of time-of-flight, almost the entire atomic mass range (7-250 m/z+) can be determined in individual particles allowing for the identification and seperate quantification of natural and engineered nanoparticle populations. In general elemental and isotopic ratios enable to differentiate nanoparticle populations (natural, incidental and manufactured) and deliver information regarding chemical composition and structure. In this work the utility of spICP-TOF-MS is demonstrated in the analysis of natural waters and soil particles, exemplifying the potential of this technique to monitor nanoparticles and processes such as aggregation, accumulation and pollutant (co-)transport. Examination of elemental compositions

of particle constituting elements as aluminum, silicon, iron, and manganese provides the information on the composition of natural mineral nanoparticles and co-occurrence of other elements, such as lead and copper demonstrate potential transport of other contaminants. Colloid facilitated transport is further demonstrated in the analysis of soil particles extracted from a cadmium/antimony mine, where arsenic bound to iron-bearing minerals can be detected and quantified. The development of this technique provides an avenue to not only discriminate engineered nanoparticulate contaminants from natural nanoparticle populations but may also further develop our understanding of nanogeochemical processes in the environment.

Suspended particulate matter (SPM): The known unknown in nanomaterial risk assessment

H. Walch, Environmental Geosciences EDGE, Centre for Microbiology and Environmental Systems Science / Environmental Geosciences; A. Praetorius, A. Mackevica, F. von der Kammer, T. Hofmann, University of Vienna / Environmental Geosciences

In light of regulations' requiring environmental fate assessment of engineered nanomaterials (ENMs), a major distinctive feature of ENMs – their particulate nature – precludes direct application of testing protocols or fate models designed for dissolved substances. In the aquatic environment particle-particle interactions (influencing ENM transport, behaviour and uptake) need to be considered. These include homoaggregation among ENMs and heteroaggregation with natural suspended particulate matter (SPM). From an ENM particle's perspective, SPM surfaces are omnipresent, as size and most likely number concentrations exceed those expected for ENMs. Thus, heteroaggregation is assumed to be the dominant process. Covering heteroaggregation in fate assessment requires a thorough scientific process understanding and informed simplifications of the same, feeding into the design of controlled experiments that allow deriving fate parameters. The most blatant "known unknown" is the interaction of ENMs and natural SPM. To fill this gap, process-relevant, near-natural SPM analogues are needed: natural SPM is very complex, featuring flock-like structures composed of various minerals and organics from the molecular level to microorganisms or detritus. Compositions, concentrations and sizes are dynamic in space and time. Hence, a mere mineral analogue is too simplistic, while attempts to rebuild natural SPM from major mineral fractions identified did not arrive at similar flocks. Reviewing available literature on natural SPM, we identified the heterogeneity of physicochemical surface characteristics as a crucial feature and took a conceptual approach, selecting mineral and organic components based on the interplay of abundance, physicochemical heterogeneity and realistic mass ratios. Here we present our resulting SPM analogues: complex flocks consisting of illite, hematite, quartz and tryptophan (proxy for microbial exudates), representing heterogeneity of natural SPM. They are reproducible and stable in batches, but at the same time dynamic when varying hydrochemistry – reflecting natural processes of flock association/dissociation. For the first time, such near-natural analogues were employed in heteroaggregation studies with ENMs, allowing more environmentally relevant conclusions for ENM fate assessment and modelling. However, the scope may also be extended to other particulate contaminants like micro-/nanoplastics, soot or tire wear – and perhaps beyond...

Predicting nanomaterial fate in the environment using a spatiotemporal multimedia model: An application to the River Thames, UK

S. Harrison, NERC Centre for Ecology and Hydrology / Environmental Contaminants; V. Keller, Centre for Ecology and Hydrology; E. Dumont, Waterschap Noorderzijlvest; M.G. Hutchins, Centre for Ecology and Hydrology; R. Williams, Centre for Ecology & Hydrology Maclean Building; J.T. Quik, RIVM / DMG; J. Kuenen, A. Manders-Groot, TNO; M. Baccaro, Wageningen University / Toxicology Division; N. van den Brink, Wageningen University / Dept of Toxicology; S. Lofts, NERC Centre for Ecology & Hydrology / Shore Section

The increasing use of engineered nanomaterials (ENMs) in modern society means an increased risk of release to the environment, either during their production, use or at end-of-life. It is therefore crucial that we are able to assess where and in what form ENMs end up in the environment. However, the particulate nature of ENMs and the fact that their transformations are driven by kinetic rather than equilibrium processes necessitates the creation of nano-specific tools to enable such assessment. Modelling plays a key role in predicting ENM fate, allowing us to fill gaps where measurement data are not available and to explore theoretical scenarios. Recently, there has been significant progress to this end, but models published to date have been limited in spatial or temporal resolution, and often consider only one or two environmental compartments. Work within the Horizon 2020 project NanoFASE (Nanomaterial Fate And Speciation in the Environment) aims to address this. The NanoFASE model, under development as part of this project, will be the most advanced spatiotemporal multimedia model of ENM fate, speciation and biouptake to date. The model represents a catchment by subdividing it into a grid of regular size, each grid cell containing one or more environmental compartments – in this example, soils, freshwaters and their bed sediments. Each compartment acts as a separate reactor for transport and fate processes, including percolation of water through soil, erosion of topsoil into surface waters, bioturbation of soils, river discharge, sediment deposition/resuspension, and ENM–specific processes such as heteroaggregation with river sediments, dissolution and attachment (i.e. to the soil matrix). Here, we present the model as applied to the Thames catchment in the UK, in doing so highlighting the importance of a number of nano-specific and non-nano processes to NM fate, such as bioturbation of soils, attachment to the soil matrix and deposition/resuspension to/from bed sediment. The NanoFASE model will be further developed for ENMs with more complex transformations such as dissolution and chemical transformation, and kinetic models for uptake by biota will be incorporated. Model outputs will be used to help validate lower-level screening models, such as SimpleBox4.0-nano, relevant for chemicals regulation.

Assessing dissolution of silica nanoparticles in aqueous media

M. Maceroni, Adolphe Merkle Institute - University of Fribourg / BioNanoMaterials; A. Petri-Fink, B. Rothen-Rutishauser, F. Schwab, Adolphe Merkle Institute / BioNanomaterials Group

While the application range of SiO_2 nanoparticles (SiO_2-NPs) is broadening, many of the current and new uses can increase their accumulation in the environment. First predictions for engineered SiO_2-NP concentrations in environmental surface water are 0.12 μg/L, and the mean concentration in soil is estimated to be 0.43 μg/L [1]. Therefore, it is crucial to gain more information about the degradation of SiO_2-NPs in the environment, which is currently scarce. Here, we present the results of a method development that was used to quantify the dissolution rate of SiO_2-NPs in aqueous media. Silica was quantified using inductively coupled plasma optical emission spectroscopy (ICP-OES) and a colorimetric assay. After initial tests of a variety of classic dialysis membrane systems, we adopted the membrane-free setup presented in Figure 1A. This allows direct measurements of the unaltered dissolution rate. To validate this setup, we quantified the dissolution SiO_2-NPs at pH 11 over 72 h in parallel with a membrane-free and a membrane setup. The high pH 11 was chosen because of the known fast base-catalyzed hydrolytic degradation of SiO_2 in this pH range [2]. Using an initial concentration of 300 mg SiO_2/L, complete dissolution was observed within the first 50 hours in the membrane-free setup. The data was fitted to a *pseudo*-first order kinetics model $d(t) = d_{max}(1-e^{-kt})$, where d is the percentage of dissolved Si. This allows estimating a half-life of about 10.2 hours for SiO_2-NPs in Milli-Q at pH 11. The particle dissolution was confirmed by the TEM micrograph. We currently use this system to evaluate particle dissolution at environmentally relevant pHs. Membrane-free dissolution setups are a versatile tool to produce data for the fate and behavior of SiO_2-NPs in aqueous media which is important for the regulation of this nanomaterial. Formation and transformation of carbon nanoparticles from environmental sources

G. Sigmund, University of Vienna | Agroscope / Chair of Analytical Chemistry and Water Chemistry; S. Castan, University of Vienna / Department of Environmental Geosciences; C. Jiang, Nankai University / College of Environmental Science and Engineering; T. Hüffer, University of Vienna / Department of Environmental Geosciences; W. Chen, Nankai University; M. Elsner, Technical University of Munich / Chemistry Department, Chair of Analytical and Water Chemistry; T. Hofmann, University of Vienna / Environmental Geosciences

The last decade of environmental carbon nano-science has often focused on understanding the behavior of well-defined engineered carbon nanoparticles (eCNPs). However, in the natural environment more complex and heterogeneous carbon nanoparticles deriving from pyrogenic and petrogenic sources (pCNPs) are more than four orders of magnitude more abundant. The sources of pCNPs include fossil fuel combustion, forest fires, fossil coal, activated carbon and biochar application. A key aim of this presentation is to compare and transfer findings from studies on eCNPs to the fate and transformation of the more heterogeneous pCNPs. Findings from previous investigations into the chemical, physical, and biological transformations of larger heterogeneous carbonaceous particles, as well as of eCNPs, can help us to understand the transformation of pCNPs. To bridge findings on colloidal behavior, particulate transport and interactions with NOM from eCNPs to pCNPs a literature review was recently published (doi: 10.1039/c8en00676h). Based on the knowledge gaps identified, we designed a first study on soot particle transformation and colloidal behavior. We review key processes and factors important for pCNP transformation and discuss results from an experimental study with soot. Based on our findings, future research on pCNPs should further investigate pCNP formation and their transformation in natural environments, specifically focusing on changes in porosity, and on interactions with non-carbonized, tar, and mineral phases, which have commonly not played important roles for eCNP research.

Influence of weathered multi-walled carbon nanotubes on the distribution of the biocide triclocarban in a sediment-water system
L. Benner, I. Politowski, RWTH Aachen University / Institute for Environmental Research; M.P. Hennig, RWTH Aachen University; A. Schaeffer, RWTH Aachen University / Institute for Environmental Research
Multi-walled carbon nanotubes (MWCNT) are widely used nanomaterials in a variety of different products and processes, and are well-known for their high sorption capacity. Due to increasing usage and production, exposure to the aquatic environment, either accidentally or via disposal of CNT-containing products, might increase likewise. Weathering processes like sunlight radiation can alter nanoparticle properties and lead to changes in their environmental behaviour. The retention time of MWCNT in the water phase is very short; due to agglomeration and aggregation processes. They preferably settle down to sediments, which act as sink for CNT and other pollutants. During their residence time in the water phase they may interact with water dissolved xenobiotics, like triclocarban (TCC) and alter the fate of these substances. In the present study MWCNT were irradiated by simulated sunlight for 90 d. These weathered MWCNT (wMWCNT) were used to investigate their influence on fate and distribution of the biocide TCC in a sediment-water system. TCC was chosen because of its hydrophobic properties and strong affinity to sorb on MWCNT. ^{14}C-TCC and wMWCNT were shaken for 2 h before application to the system to ensure complete adsorption (loading process). Samples were incubated after application for 181 d in the dark at 19 °C (weekly aeration). Work up of samples was performed according to OECD Guideline 308. Residence time of radioactivity in the water phase was significantly prolonged in the presence of wMWCNT. In presence and absence of wMWCNT DT_{50} values for dissipation from the water phase of 0.42 d and 0.25 d, respectively, were calculated. Sedimentation time of ^{14}C-wMWCNT alone was assessed in a second study, using the same experimental set up. A DT_{50} of 3.21 d was calculated for the dissipation of ^{14}C-wMWCNT from the water surface. The amount of radioactivity found in extractable and non-extractable TCC residues from sediment was not altered significantly. An investigation of metabolites in methanol extracts using radio-thin layer chromatography could confirm the presence of metabolite 4-chloroaniline in one sample without wMWCNT. Presence of ^{14}C-TCC was confirmed in all tested samples. Mineralisation of ^{14}C-TCC was significantly reduced in presence of wMWCNT. Acknowledgements: The work is supported by the European Project NANO-Transfer that receives funding from the Bundesministerium für Bildung und Forschung (BMBF) under agreement with the FP7 ERA-NET SIINN.

Examining Behavioural Effects of Chemical Contaminants and Other Stressors on Behaviour, Ecology and Evolution of Wildlife

The effect of two pesticides on the olfactory-mediated antipredator response of zebrafish (Danio rerio)
S. Volz, RWTH Aachen University / Institute for Environmental Research; J. Hausen, University of Bonn / Institute for Genomic Statistics and Bioinformatics; S. Schiwy, H. Hollert, RWTH Aachen University / Institute for Environmental Research
Escaping predation is essential for the survival of any organism. Fish are warned about the presence of predators via an antipredator substance that is released from the skin of an injured conspecific. This substance is perceived by the olfactory system and initiates an antipredator response that is specific for the respective fish species. If an individual fails to respond to such an antipredator cue, chances of survival decrease substantially. The aim of the present study was to assess the effects of two pesticides on the antipredator response of zebrafish. Furthermore, an analysis script for the automated identification of certain behaviors from tracking data should be developed to accelerate the evaluation process. To this end, zebrafish were exposed to 0.01 % DMSO (solvent control), 2, 5 and 20 μg/L chlorpyrifos or 10, 100 and 300 μg/L linuron for 24 hours. Hereinafter, behavioral trials were conducted and videotaped. Following twenty minutes of acclimatization, either water (blank stimulus) or skin extract (alarm cue) was delivered and fish behavior was recorded for another ten minutes. Subsequently, video recordings were analyzed using EthoVision XT 11.5 (Noldus, Netherlands) and tracking data was was further analyzed using R (R Core Team) to automatically identify the behaviors of interest – namely bottom-dwelling, freezing and erratic movements. Following the delivery of skin extract, significantly more zebrafish exposed to 0.01 % DMSO exhibited bottom-dwelling and freezing behavior compared to following the delivery of water. Exposure to 100 μg/L linuron resulted in a decreased number of fish showing bottom-dwelling behavior compared to the skin extract solvent control, however, in the highest test concentration, this tendency was not visible anymore. Chlorpyrifos significantly reduced the number of bottom-dwelling fish in a concentration-dependent manner. Whereas the exposure to linuron did not affect freezing behavior, following exposure to chlorpyrifos fish froze significantly less. In conclusion, we showed that the antipredator behavior of zebrafish was significantly impaired following exposure to chlorpyrifos. As this behavior is essential for the survival of fish, its impairment could have fatal consequences for the individual. In addition, we developed a script for the automated analysis of the antipredator behavior of zebrafish, which greatly simplified and accelerated data evaluation.

Determining the effects of psychotropic drugs in a marine and freshwater amphipod
S.A. Kohler, University of Portsmouth / Aquatic Biology; A. Ford, University of Portsmouth / Biological Sciences; M. Parker, University of Portsmouth / Biological Science
The use of behaviour in ecotoxicology is increasing, providing a link between biochemical and ecological effects of environmental contaminants. Psychotropic drugs are designed to modulate behaviours in humans, and preclinical studies have demonstrated that these compounds can alter behaviours in aquatic vertebrates. The effects of behavioural modulating drugs have been tested from a pharmacological discipline using anxiety-like behaviours including thigmotaxis and scototaxis on mice and zebrafish, using well-defined behavioural assays. These methods have been translated to ecotoxicological studies on vertebrates but comparatively few have been done on invertebrate species. This ongoing study aims to translate these techniques to model crustaceans for the purpose of high-throughput assessment of environmental risk, using both antidepressant and anti-anxiety compounds with different modes of action. Specimens of the marine amphipod, *Echinogammarus marinus* and the freshwater amphipod *Gammarus pulex* were exposed to the SSRI fluoxetine, or the BZD Oxazepam at a range of concentrations (0.001-1 µg/L). Swimming behaviours, as well as thigmotaxis and phototaxis were analysed using custom choice chambers in a DanioVision observation chamber with EthoVision software after 1 day, 1 week, and 2 weeks of exposure. Behaviours were observed under a light-dark cycle with 'light on' used as a stimulus to initiate behaviours. Both *E. marinus* and *G. pulex* showed alterations in swimming activity between light and dark cycles. Differences in velocity were also observed with duration of exposure to both compounds in *E. marinus* but not between treatments. In choice experiments, both species showed negative phototaxis and positive thigmotaxis during light cycles. Significant differences were observed in choice behaviours between treatments and with length of exposure (p=< 0.05) for Fluoxetine but not with Oxazepam. Results indicate that behavioural modifying compounds can have significant effects on velocity and phototactic behaviour. This ongoing study is further trying to ascertain whether compounds with differing modes of action can have different effects on amphipod behaviours, and whether seemingly similar species exhibit differences in their sensitivity to behavioural modifying compounds. We discuss our results in relation to inter- and intra- species variability highlighting the need to go beyond the mean, consider phenotypic plasticity and the spread of data.

Impact of the two antidepressants citalopram and venlafaxine on brown trout (Salmo trutta f. fario) and great ramshorn snail (Planorbarius corneus)
M. Ziegler, University of Tubingen / Animal Physiological Ecology; S. Tisler, University of Tuebingen / Environmental Analytical Chemistry at the Center for Applied Geosciences; C. Zwiener, Environmental Analytical Chemistry, Center for Applied Geoscience, University of Tuebingen / Geosciences; R. Triebskorn, University of Tuebingen / Animal Physiological Ecology
Citalopram (CIT) and venlafaxine (VEN) are the most frequently prescribed antidepressant drugs in Germany. CIT belongs to the SSRIs (selective serotonin reuptake inhibitors) and VEN to the SSNRIs (selective serotonin and noradrenalin reuptake inhibitors). Due to high consumption rates and poor elimination during wastewater treatment both antidepressants can be found in concentrations up to 1 μg/L in surface waters. Since up to now, consequences of the exposure to these pharmaceuticals for aquatic wildlife are far from being understood, we investigated responses of brown trout and great ramshorn at different biological levels. Brown trout eggs were chronically exposed in the eyed-ova stage to 0, 1, 10, 100, 1000 μg/L CIT and VEN in a semi-static three block design at 7 and 11°C for 5 months. Juvenile fish and snails were exposed in a similar design for 4 weeks at 7 respectively 11 °C. As apical endpoints, mortality, weight and length, and, for brown trout larvae only, hatching rate and heart rate were recorded. During the experiments, behaviour of fish was quantitatively assessed. Also water concentrations of citalopram were analysed and nominal concentrations complied with real concentrations. After exposure to 1000 μg/L CIT, weight of fish and snail, as well as length of fish were significantly reduced. In general, fish exposed to both antidepressants showed increased swimming activity and a predominant sojourn in the upper half of the aquaria. In addition, it became obvious, that in an artificial swimming measurement device (small aquaria of 17x17x8,5 cm), which had to be brightly illuminated to obtain optimal tracking results, brown trout larvae were highly active except for those exposed to 1000 μg/L CIT, which moved significantly less with a lower velocity than control fish under these stressful conditions. Snails exposed to VEN showed a significant increase in sole detachment. Mortality in fish and snails as well as hatching rate and heart rate of

brown trout larvae were not influenced by the two antidepressants tested so far. In general, the results of this study make evident that both antidepressants evolve their anxiolytic effects also in non-target organisms like brown trout or invertebrate species like the great ramshorn snail. The present study is part of the project Effect-Net which is funded by the Ministry of Science, Research and the Arts of the Land of Baden-Württemberg within the framework of the Water Research Network Baden-Württemberg.

Antidepressants in the water: effects of field-realistic fluoxetine exposure on sociability and anxiety-related behaviour of fish
J.M. Martin, Monash University / School of Biological Sciences; M.G. Bertram, Monash University / Biological Sciences; M. Saaristo, Monash University / School of Biological Sciences; J. Fursdon, Monash University / Biological Sciences; S. Hannington, Monash University / School of Biological Sciences, Monash University, Victoria, Australia; B.W. Brooks, Baylor University / Department of Environmental Science; B. Wong, Monash University / School of Biological Sciences
Pharmaceutical pollution is a serious, global issue. Indeed, the rise in production and diversification of pharmaceuticals—and synthetic chemicals more generally—is equal to, or exceeds, most other recognised drivers of global change. Of particular concern are pharmaceutical pollutants with evolutionarily conserved drug targets and the ability to alter biological function at minute concentrations. The antidepressant fluoxetine is one such pollutant, which has the potential to disrupt behavioural pathways through impacts on the central nervous system and neuroendocrine system. Despite this, it remains unclear whether environmentally relevant fluoxetine exposure can adversely impact behavioural processes in wildlife. To address this knowledge gap, we investigated effects of two field-realistic concentrations of fluoxetine (x: 60.5 and 351.9 ng/L) on sociability and anxiety-related behaviours in male and female eastern mosquitofish (*Gambusia holbrooki*). Sociability and anxiety-related behaviours are known to regulate important inter- and intraspecific interactions and, if disrupted, have the potential to impact the fitness of exposed wildlife. Additionally, we measured whole-body tissue concentrations of fluoxetine and norfluoxetine (fluoxetine's primary metabolite). We found that fluoxetine exposure altered anxiety-related behaviour, whereas no significant effect of exposure on sociability was observed. What is more, observed impacts of fluoxetine on anxiety-related behaviour were sex-specific, with females showing reduced anxiety-related behaviour at the lower dosage, while males showed an increase at the higher dosage. Fluoxetine and norfluoxetine were present in the tissue of male and female fish in both the low (x: 5.5 and 10.1 ng/g, respectively) and high dosages (x: 10.3 and 26.8 ng/g, respectively). Further, the bioconcentration of fluoxetine and norfluoxetine was size-dependent, with smaller fish showing higher relative tissue concentrations of fluoxetine and norfluoxetine. In combination, these findings provide evidence that fluoxetine at field-detected levels can alter the behaviour of fish, but also suggest that the magnitude and direction of these effects are dependent on sex and dosage. Moreover, our results provide insights into the apparent disparity of previously reported behavioural effects resulting from fluoxetine exposures.

Fish larve response to nanoplastics: Is behavior as a sensitive endpoint?
D. Correia, CESAM University of Aveiro / Department of Biology; A.P. Gonçalves, University of Aveiro / Biology Department & CESAM; M.A. Martins, University of Aveiro / Physics Department & CICECO; A.M. Soares, University of Aveiro / department of Biology & CESAM; M.L. Pereira, CESAM University of Aveiro / Department of Biology & CICECO; I. Domingues, University of Aveiro / department of Biology & CESAM; M. Oliveira, RMS-TekebBio, LDA
The presence of plastics in the environment is a global issue. In the environment plastics can degrade into increasingly smaller particles reaching the nanometer size which increases their potential to be incorporated by organisms. However, the current understanding of the consequences of these particles can be considered still scarce. The knowledge of the effects of nanoplastics to aquatic organisms may be considered limited, particularly in terms of effects on behavior. Behavior, as the outcome of many developmental and physiological processes resultant from interactions between the organisms and the surrounding environment, has attracted the attention of ecotoxicologists as a sub-lethal endpoint with ecological relevance. If biochemical effects are translated into fitness-related traits such as decreased ability of respond to stimulus, escape from predators and pernicious environments, they can have a strong impact on the ecosystem functioning on a long term. This study aimed to assess if 50 nm polystyrene (PS) and polymethylmethacrylate (PMMA) nanoparticles could affect fish larvae behavior, after 96 h. Data showed that behavior endpoints were sensitive to exposure to nanoplastics emphasizing the potential pernicious effects of these particles in the environment.

487
The Saturday night fever - effect of benzodiazepine cocktail on fish behavior and bioconcentration
D. Cerveny, Umea Universty / Department of Chemistry; T. Brodin, Swedish University of Agricultural Sciences (SLU) / Department of Wildlife, Fish and Environmental Studies; P. Cisar, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters; J. Fick, Umea University / Department of Chemistry
The aim of this study was to describe possible synergistic effects of pharmaceutically active compounds (PhACs) on fish behavior. Four benzodiazepines (oxazepam, temazepam, bromazepam, and clobazam) were chosen as an example of PhACs with similar mode of action that also frequently occur together in the environment. Juvenile European perch (*Perca fluviatilis*) was used as an indicator fish species to study behavioral changes induced by both exposure to single compounds and their mixtures. Fish were exposed to target PhACs at two concentration levels (8 and 0.5 μg L^{-1}), where the low dose is considered as environmentally relevant. Unique approach using a structured light sensor was used for automated tracking of fish in three-Dimension during the boldness, sociality, and activity trials. All fish were sacrificed after the experiment, muscle tissue was sampled, and levels of target PhACs were analyzed using the method of liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS). The potential to modify fish behavior in this study strongly depended on the target compound, specific behavioral trait, and concentration level. However, clobazam expressed the highest potential to alter boldness, sociality, and activity of studied fish. No clear evidence of synergistic effects was found, as the exposure to benzodiazepines mixture mostly resulted in similar effect as exposure to the most potent individual compound in each behavior trial. Bioconcentration also differ greatly between the target compounds. Temazepam was found at the highest levels in fish muscle tissue, reaching the mean concentration of 52 ng g^{-1} after seven days of exposure to 8 μg L^{-1}. Five times lower mean concentration was found in case of bromazepam that was the compound with lowest bioconcentration potential. Relatively high concentrations of oxazepam were also measured in muscle of fish exposed to temazepam. This finding is most likely due to fish metabolic activity, as oxazepam is known as a transformation product of some other benzodiazepines. Except of oxazepam, where both waterborne exposure and production via metabolic activity occurred, all other target compounds express lower bioconcentration potential in mixture than in individual exposure.

Benefits of BiER: How Biotransformation and Elimination Rate Related Science Can Improve the Regulation and the Sustainable Use of Chemicals

488
Making the IVIVE formalism fit for regulatory purposes
S. Krause, K. Goss, Helmholtz centre for environmental research - UFZ / Analytical Environmental Chemistry
The assessment of the bioaccumulation potential is one criterion in the evaluation of chemicals regarding their potential harmfulness for the environment. Among the processes influencing bioaccumulation of a chemical, elimination via biotransformation is the only one that cannot be estimated from physico-chemical or physiological information. At the same time, however, elimination via biotransformation can be the key parameter to reduce the internal concentration of a hydrophobic chemical and, by this, preventing bioaccumulation. Accordingly, biotransfomation has to be accounted for in bioaccumulation assessment and experimentally determined biotransformation rates are required. In line with the effords of reducing the use of animal testing, the method of choice for determination of biotransformation rates are in vitro experiments and subsequent extrapolation to the in vivo rate. Currently, there are often significant discrepancies between extrapolation results and in vivo observations reported. When evaluating reasons for the discrepancies between predictions of biotransformation kinetics from in vitro data and in vivo observations, we identified a couple of potentially relevant processes that are currently not considered in the extrapolation procedures: the potentially limited delivery of the chemicals in vivo due to slow permeation of the chemical into the metabolically active cells or due to slow desorption from binding plasma-proteins, the potentially decreased uptake of the chemical due to first-pass effects, the potentially higher biotransformation capacity of the liver due to the tubular architecture of blood capillaries or the potentially increased elimination due to extrahepatic metabolism. To estimate the relevance of the above mentioned processes under physiological conditions, we evaluated experimental data from the literature in suitable physiologically based modelling approaches. This evaluation helps to improve our understanding of the complexity that is required for reliable in vitro-in vivo-extrapolation and how the currently observed discrapncies between extrapolation results and in vivo observations could be solved. Furthermore, the generated insights are not only relevant for bioaccumulation assesments in fish, but provide also useful information in the emerging field of bioaccumulation assessment in terrestric organisms.

489
Evaluation of major uncertainties as part of in vitro-in vivo extrapolation to predict the bioaccumulation potential of fragrance chemicals
H. Laue, Givaudan Schweiz AG / Fragrances S & T; L. Hostettler, Givaudan

Schweiz AG; K. Jenner, Givaudan / Global Regulatory Affairs & Product Safety; G. Sanders, Givaudan International SA / Regulatory Affairs and Product Safety; J.A. Arnot, ARC Arnot Research & Consulting / Adjunct Professor, Department of Physical & Environmental Science/Department of Pharmacology and Toxicology; A. Natsch, Givaudan Schweiz AG / Fragrances S &T

Bioaccumulation in aquatic species is a critical endpoint in the regulatory assessment of chemicals which usually involves the determination of the bioconcentration factor (BCF) in fish. *In vitro* systems measuring *in vitro* intrinsic clearance rates of chemicals have been established as alternative methods to refine *in silico* BCF models which are based on hydrophobicity (i.e. log Kow) and were recently adopted as new OECD test guidelines (319A,B). *In vitro-in vivo* extrapolation (IVIVE) models can then be applied to estimate liver clearance and a "whole body" biotransformation rate constant (k_{MET}) to refine BCF predictions. Several published studies show a clear tendency for overprediction of predicted BCFs based on IVIVE. Errors in estimates of the fraction unbound (fu) and the impact of the *in vitro* test concentration were discussed as possible reasons. With the OECD approved TGs available, testing and optimizing the IVIVE models is now of high relevance. The goal of this study was to provide a large dataset on industrial relevant chemicals, mainly fragrance chemicals, with measured *in vivo* BCF data for which we determined biotransformation rates using liver S9 sub-cellular fractions from rainbow trout (RT-S9). BCFs were predicted with an IVIVE model parameterized with different assumptions to evaluate which of the postulated reasons could account for the commonly observed overprediction of BCFs. Fu was measured in RT-S9 and trout serum using a vial equilibration method and lower test concentrations were applied for a subset of 6 chemicals. The majority of the 22 fragrance chemicals was moderately to rapidly transformed in RT-S9, whereas 5 chemicals with measured BCFs >2000 L/kg were not biotransformed. A systematic overprediction of the BCFs was observed for the majority of the chemicals tested using the standard IVIVE model (fu calculated), whereas predicted BCFs were similar to *in vivo* BCFs when the correction factor fu was set to 1. The incorporation of measured fu values in the IVIVE model parameterization and lowering the test concentrations below 1 mM did not significantly improve the BCF predictions. This is the first significant dataset tested under the new OECD conditions. Neither testing below 1 μM, nor incorporation of measured fu in the IVIVE model avoided the commonly observed tendency to overpredict BCFs. This suggests that these experimental refinements cannot resolve the mispredictions and further improvements of IVIVE models are needed.

A tiered testing strategy for rapid estimation of bioaccumulation by a combined modelling - in vitro testing approach: derivation of kinetic rate constants in different in vitro models

J. Stadnicka-Michalak, EPFL - Swiss Federal Institute of Technology; J.A. Arnot, ARC Arnot Research & Consulting / Adjunct Professor, Department of Physical & Environmental Science/Department of Pharmacology and Toxicology; N. Bramaz, Eawag Swiss Federal Institute of Aquatic Science and Technology / Environmental Toxicology; N. Bury, University of Suffolk / School of Science, Technology and Engineering; M. Embry, Health and Environmental Sciences Institute HESI; J.A. Fitzgerald, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology; C. Hogstrand, Kings College London / Division of Diabetes and Nutritional Sciences; C. Kropf, University of Bern / Centre for Fish an Wildlife Health; H. Segner, University of Bern / Centre for Fish and Wildlife Health; R. Schoenenberger, K. Schirmer, Eawag Swiss Federal Institute of Aquatic Science and Technology / Environmental Toxicology

Quantification of chemical toxicity continues to be based mainly on measurements of external exposure. Yet, in order to understand, interpret and extrapolate toxic effects, using internal concentrations of chemicals is more suitable. Though these can be measured, being able to predict them would be much more efficient and feasible. Predicting chemical internal concentrations accurately is, however, still challenging as biotransformation processes can strongly influence the extent to which chemicals accumulate in fish. Existing approaches thus far are based on the assumption that biotransformation in the body solely occurs in fish liver. Since this is unlikely to be true, this assumption may result in underestimating the biotransformation of chemicals in fish. Therefore, in our study, in addition to liver, we focus on rainbow trout gill and intestine as potential sites of chemical biotransformation. We have determined *in vitro*biotransformation rates for several chemicals in an array of models based on rainbow trout *(Oncorhynchus mykiss)*: a primary gill cell culture, S9 fractions of liver and intestine, as well as permanent cell lines from, respectively, gill (RTgill-W1), liver (RTL-W1) and intestine (RTgutGC). Except for 2,4,6-Tribromophenol (TBM), the biotransfomration of chemicals was the most significant in liver, followed by intestine, followed by much slower biotransformation observed in gills. The *in vitro*intrinsic clearance (CL_invitro) of TBM, determined with liver S9 fraction, was one order of magnitude lower than for other chemicals while it was in the same order of magnitude as for the other chemicals for the primary gill cell system. For TBM no biotransformation was observed in permanent cell lines. For all other chemicals, the respective CL_invitro were comparable across the different *in vitro*systems. Our study shows that chemical biotransformation takes place not only in liver but also in fish intestine and gills. Thus, accounting for their CL_invitro could lead to more accurate estimation of chemical accumulation and bioconcentration factors (BCF). In addition, while the biotransformation capability of permanent cell lines requires further investigation, they could potentially be applied as a first screen to confirm that a compound is biotransformed in fish. Finally, the new measured datasets for biotransformation in various biological compartments and tissues could provide quantitative information to support a Weight of Evidence approach.

An attempt to account for biotransformation in bioaccumulation models for aquatic invertebrate species.

A. Ratier, Irstea Lyon; C. Lopes, Université Lyon 1, UMR CNRS 5558 / Laboratory of Biometry and Evolutionnary Biology; H. Budzinski, University of Bordeaux / EPOC LPTC UMR5805 CNRS; P. Labadie, UMR CNRS EPOC Universite Bordeaux / UMR 5805 EPOC; O. Geffard, Irstea / UR RIVERLY Laboratoire Ecotoxicologie; M. Babut, Irstea Lyon / UR RIVERLY Laboratoire Ecotoxicologie

Toxicokinetic (TK) models describe the process of bioaccumulation as a balance between contaminant uptake from different sources (e.g. water or diet), and their elimination by different processes (excretion, growth and/or biotransformation). TK model parameters are generally estimated by fitting the model to data from short-term exposures of organisms under controlled laboratory conditions. The model fit is often based on a deterministic approach, which cannot take simultaneously into account different types of data (e.g. bioaccumulation and growth data), nor account for correlations between parameters. In this context, the uncertainty related to model parameters, and thus to model predictions, is not correctly estimated. Moreover, in invertebrates, biotransformation is generally neglected, assuming a low metabolic activity. However, some species such as the amphipod *Gammarus pulex* are capable to metabolize a wide range of organic chemicals. The aim of our study is to incorporate biotransformation into a generic TK model for aquatic invertebrates, based on a unified Bayesian framework. We attempted to adapt one of the methods described in the literature for estimating biotransformation rate (k_m) values, so as to estimate simultaneously model parameters from uptake and elimination data. We illustrate this approach by fitting the generic model with some data available in the literature for several invertebrate species exposed to different chemicals using Bayesian inference (R and JAGS softwares). This preliminary attempt suggests that considering the biotransformation process simultaneously to other processes in a generic TK model is feasible, as it was applied to several invertebrate species and chemicals. The Bayesian approach is of real added value to estimate model parameters and to access to a more accurate assessment of uncertainty around estimates and thus TK model predictions. We will further consolidate this attempt with toxicokinetic data from an ongoing experiment in our laboratory involving pyrene, its metabolite 1-OH-pyrene and the amphipod *Gammarus fossarum*.

492

Biotransformation Leading to Increased Toxic Metabolites: an Overlooked Risk in Aquatic Organisms?

Q. Fu, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Department of Environmental Chemistry; D. Fedrizzi, Eawag Swiss federal Institute of Aquatic Science and Technology; V. Kosfeld, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; C. Schlechtriem, Fraunhofer IME / Department Bioaccumulation and Animal Metabolism; J. Hollender, Eawag / Environmental Chemistry

Numerous micropollutants have been detected concurrently in aquatic systems. Biotransformation plays a critical role in the bioaccumulation and toxicity of these chemicals by altering their hydrophobicity and toxic potency to certain species. This study aimed to elucidate how biotransformation change the toxicokinetics and toxicity of parent compounds and to gain a better comprehensive understanding of the risk for the aquatic environment. Therefore, we first investigated bioaccumulation and biotransformation of the widely used nonsteroidal anti-inflammatory drug diclofenac in two representative aquatic invertebrates, i.e. *Gammarus pulex* and *Hyalella azteca*. Second, we compared acute toxicities and toxicokinetics of parent compound diclofenac and its major metabolites in *G. pulex* and *H. azteca*. Furthermore, we validated its widespread occurrence in other chemicals and other aquatic organism (fish *in vitro*) at environmental relevant level. Diclofenac methyl ester was the primary metabolite in all three species. The methylation was also observed for triclosan and bezafibrate with distinct structures and was further determined in organisms exposed to environmentally relevant levels of chemicals, suggesting that methylation might be a general process in aquatic organisms. Bioaccumulation factors (BAFs) of diclofenac methyl ester were 229 L kg_{ww}^{-1} and 84 L kg_{ww}^{-1} in *H. azteca* and *G. pulex*, which were 168-458 times higher than the parent compound diclofenac in these two species. This can be explained by the higher hydrophobicity (log D_{ow} = 0.9 for diclofenac; log D_{ow} = 4.4 for diclofenac methyl ester at pH 7.9). The LC_{50}s of diclofenac methyl ester was decreased by 3 order of magnitude (432 times) to 0.53 L mg^{-1} in *H. azteca* in agreement with the higher bioaccumulation. Toxicokinetic modelling in *H. azteca* suggests that the secondary major BTP diclofenac taurine continuously accumulated in the organisms and resulting in prolonged half-life. This could be explained by ion trapping of the ionized diclofenac taurine. Our results show that methylation of diclofenac forms diclofenac methyl ester, which leads to higher bioaccumulation potential and exerts higher toxicity to aquatic invertebrates. In addition, diclofenac taurine is highly accumulated in *H. azteca*. The findings suggest that biotransformation leads to more hydrophobic compounds which should be taken into consideration for future risk assessment.

493

Integrating bioaccumulation assessment tools for mammals: from data collection to in silico modelling

L. Bertato, University of Insubria; I. Casartelli, University of Insubria / Department of Theoretical and Applied Sciences DiSTA; A. Sangion, University of Insubria / Department of Theoretical and Applied Sciences (DiSTA); K. Foster, Karen Foster Environmental Research / Adjunct Professor, Trent University, Applications of Modelling & Quantitative Methods (AMOD); J.A. Arnot, ARC Arnot Research & Consulting / Adjunct Professor, Department of Physical & Environmental Science/Department of Pharmacology and Toxicology; E. Papa, University of Insubria / Department of Theoretical and Applied Sciences

Toxicokinetic (TK) processes such as chemical absorption, distribution, biotransformation and excretion (ADBE) are fundamental to better understand relationships between external and internal exposures and to assess bioaccumulation in mammals. The potential biotransformation rate of a xenobiotic can be estimated using *in vitro* tests to obtain the *in vitro* intrinsic clearance (CL_{int}). Then *in vitro-in vivo* extrapolation (IVIVE) models and QSARs (Quantitative Structure-Activity Relationships) can be used to maximize the information available from *in-vitro* and *in-vivo* measurements. The integration of these different data streams in a coherent framework for the assessment of mammalian bioaccumulation is one primary objective of the CEFIC LRI ECO44 project “Integrating Bioaccumulation Assessment Tools for Mammals (iBAT-Mam)”. This work presents initial efforts to assimilate and analyze *in vitro* TK data to develop new QSARs models to predict biotransformation rates in humans. A new database of >11000 human in vitro biotransformation rate estimates derived from microsomal, S9 homogenate, and hepatocyte-based assays for >8500 organic chemicals was recently developed and critically evaluated. In the present study we conduct in-depth statistical analysis of the data and explore the possiblity of QSARs. Multivariate analysis identified structural patterns in the highly heterogeneous dataset. Principal Components Analysis revealed a good overlap of all assay media that have a similar distribution in the space defined by the theoretical molecular descriptors. Cluster Analysis was performed in order to divide the data into different structural groups. We obtained QSAR models for the different structural groups for hepatocyte and microsome media; all models are stable, robust (R^2>0.75 and Q^2_{loo}>0.70), externally validated and predictive when they are applied to generate predictions on different splitting schemes. Particular attention was given to the structural applicability domain (AD) of all the proposed models. These results demonstrate that QSAR methods can predict biotransformation rates for humans to improve bioaccumulation assessment which is important in the scientific evaluation of risk chemicals may pose to humans and the environment and is a current focus of regulatory effort. These new QSARs can also be used to extrapolate emerging *in vitro* bioassay data from programs like ToxCast, Tox21 and SEURAT to *in vivo* exposures corresponding to *in vitro* bioactivity.

Individual Variation in Ecotoxicological Research: a Change from Unwanted Noise to a Meaningful Endpoint

494

Individual variation in ecotoxicology - not only unwanted noise but a factor affecting population tolerance

M.J. Nikinmaa, K. Anttila, University of Turku / Department of Biology

Although variability is of major importance when measuring the tolerance of organisms to unfavourable environments, its importance in the survival of organisms to unhospitable environments is seldom studied in ecotoxicological research. In fact, variability is usually addressed in statistical testing only to evaluate, if the variances of different experimental groups are similar or not. If variances do not differ statistically from each other, parametric statistical testing can be used to compare means. If variances differ significantly, different transformations are used to decrease the variance differences to levels, which are acceptable for parametric statistical testing. If even transformations do not make variances statistically non-significantly different, non-parametric statistical testing about the differences between the means must be used. The whole treatment has as an outset that any change of variability is just unwanted noise, and that the only important thing is to compare the means. However, changes in variability can determine, if some organisms can tolerate the unhospitable conditions or not. Further, if the differences in variabilities between groups were only experimental error, the question must be asked: why would there be a different error in the groups, when the same methods by the same scientists are used throughout the study? We have evaluated, if ecotoxicological studies commonly have differences in the variability between treatments. Notably, it is possible that a response in variance can be seen even if the mean does not change significantly. If such a case is interpreted from the mean-centred outset, nothing happens, although the change in variability can affect the survival of some individuals of the population.

495

Variability in response between individuals and populations of fish in response to chemical exposures

E.M. Santos, University of Exeter / Biosciences College of Life and Environmental Sciences; L.V. Laing, University of Exeter / Biological Sciences; J.A. Fitzgerald, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology; T. Uren Webster, Swansea University / Department of Biosciences; L.B. Riddle, H.R. Littler, P. Robinson, The University of Exeter / Biosciences

Fish populations in natural ecosystems are exposed to a wide range of environmental stressors, from changes in biotic and abiotic factors to complex mixtures of chemical pollutants. Individuals within these populations can be exposed continuously or intermittently over their life cycle and their susceptibility to stress is dependent on multiple factors including their genetic makeup, exposure history, stage of the life cycle and health of the individuals at the time of the exposure. As a result, the response to a stressor will likely be variable between individuals within a population and also between populations. In addition, exposure to stressors can cause changes in the variability of certain parameters in the exposed population, reflecting the differential threshold for response in different individuals. Therefore, variability in the responses to stressors between individuals and populations is likely to be an important component of the mechanisms responsible to population survival in the wild. We will present examples of the variation in response to chemical stressors in fishes and discuss their likely causes. These include increased tolerance to metals in brown trout inhabiting a river with extremely high metal pollution, likely as a result of genetic adaptation; and increased tolerance to copper in a population of stickleback previously exposed to this stressor during embryogenesis, possibly mediated by epigenetic mechanisms. In addition we will discuss the impact of variable husbandry conditions on the response to chemical toxicants. Finally, we will show how exposure to copper increased the variability in Pcrit, a measure of adaptation to hypoxia, and supressed the ability of fish to acclimate to low oxygen availability in the water. These examples document the importance of considering the variation in response to stressors and its causes as part of understanding how populations of fish survive contaminated environments.

496

Physiological plasticity in changing oceans: lessons from marine bivalves and corals

S. Franzellitti, Alma Mater Studiorum - University of Bologna / Biological, Geological and Environmental Sciences; F. Prada, Alma Mater Studiorum University of Bologna / Dept. of Biological, geological and Environmental sciences; P. Valbonesi, Alma Mater Studiorum University of Bologna / Departmento of Biological, Geological and Environmental Science (BiGeA); E. Caroselli, Alma Mater Studiorum University of Bologna / Dept. of Biological, geological and Environmental sciences; T. Mass, University of Haifa / School of Marine Science; G. Falini, Alma Mater Studiorum University of Bologna / Dept. of Chemistry G. Ciamician; S. Goffredo, Alma Mater Studiorum University of Bologna / Dept. of Biological, geological and Environmental sciences; E. Fabbri, University of Bologna / Bigea Department via Selmi Bologna

It is well known that species use diverse life strategies (growth, reproduction, survival), but the mechanisms that promote and regulate this diversity remain unknown. Furthermore, elucidating the way that regulatory processes that define these paths operate under environmental pressures to control animal responses and adaptive reactions is a challenging task in environmental studies. Physiological plasticity, which describes the process of tuning organismal phenotypic traits to varying environmental conditions, within their lifetime, is at the base of a species tolerance to environmental challenges. In this regard, variations in mRNA expression profiles are explored as early-warning molecular markers of physiological plasticity and are suggeste to represent an important source of information on regulatory mechanisms governing stress responses and acclimatory processes. In this context, studies on marine invertebrates offer a remarkable opportunity to investigate how physiological plasticity may influence animal responses triggered by environmental pollutants and climate changes. We report on our ongoing research activity in which we use mussels and scleractinian corals as model organisms to infer physiological plasticity and its influence on the responses triggered by environmental changes in the marine environment. Mussels and corals are sessile calcifying organisms with simple body architecture but endowed with complex molecular and physiological mechanisms allowing them to efficiently cope with coastal marine environments where they are exposed to fluctuating environmental parameters and elevated levels of natural and anthropogenic pollutants throughout their life-cycle. We report results on the influence of physiological plasticity on mussels’ and corals’ capability to cope with environmental challenges under *in situ*(baseline physiological status) and laboratory (stress responses) conditions, allowing us to discriminate physiological and/or life history traits promoting stress tolerance and adaptation in a global change scenario. Understanding the underpinning molecular processes can contribute predicting the future of shallow-water calcifying organisms under projected scenarios of anthropogenic-induced global change

497
Context-dependent repeatable behaviour in copepods -consequences and approaches for ecotoxicology
J. Heuschele, University of Oslo; T. Lode, T. Andersen, University of Oslo / Department of Biosciences; K. Borga, Department of Bioscences, University of Oslo / Department of Biosciences; J. Titelman, University of Oslo / Department of Biosciences
In ecotoxicology, we often ignore responses of individuals and focus on average responses. Yet, both terrestrial and aquatic animals display consistent behavioural differences between individuals, in other words, "personalities". The distribution of behavioural differences within a population contains vital information for predicting population responses to novel environmental challenges. Currently, individual data for behavioural and physiological traits of small marine invertebrates are few, partly because such variation is lost within published group means and assumed normality, but also because acquiring individual data at reasonable sampling sizes can be a challenge. In toxicology, phenotypic variation is further reduced by using single strains and clones to the effect of (single) toxicants. We used an automatized imaging system to test the combined effects of copper and kairomones on swimming activity levels and development in the marine copepod *Tigriopus brevicornis*. While direct stress effects on swimming activity were weak, individuals behaved consistently different. The individually different behavior was only expressed when under the influence of kairomones, and not under copper exposure alone. This pattern indicates that copepods express repeatable, but context-dependent, behaviour. It further shows that variation in behavioural and probably other data can hide consistent differences between individuals, which could have implications for the adaptability and the ability of populations to cope with environmental challenges. In toxicology, this affects the understanding on toxicants' effect, and the realism in extracting knowledge from a laboratory monoculture to a more realistic situation including biological variation. We further tested a similar automated imaging system that can accommodate both aquatic and terrestrial small invertebrates to measure differences in developmental growth pattern. The temporally-highly resolved growth data revealed previously unidentified importance of pedigree and differences between individuals for coping with environmental stressors.

498
Variation of polychlorinated biphenyl congener profiles in the UK harbour porpoise (Phocoena Phocoena) in relation to age, gender and geographic location
R. Williams, Institute of Zoology; S. Jobling, Institute for the Environment / Institute of Environment, Health and Societies; P.D. Jepson, Zoological Society of London; J. Barber, Cefas Lowestoft Laboratory / OAN
Polychlorinated biphenyls (PCBs) are persistent and lipophilic chemical compounds that pose a health risk to humans and wildlife. Harbor porpoises are long-lived and feed at a high trophic level and therefore accumulate some of the highest levels of PCBs in wildlife. Studies typically use the sum of PCB congener concentrations to investigate PCBs in wildlife. However, less work has been done to investigate congener profiles and the factors that influence variation between individuals. It is important to study individual congeners because their toxicological effects and thresholds can vary. Interactions between congeners can cause the magnitude of their effects to increase. Hence, toxic effects of mixtures can occur at levels below the summed effect levels for the component congeners. We found congener profiles vary with age, sex and location. Significant variation was observed between adult females and subadults which is likely to be a consequence of pollutant offloading between mothers and calves. This is important because animals are receiving this dose at a time when they are most vulnerable to its effects. Understanding more about variation in congener profiles is an important step towards better understanding the potential effects and threats of PCB exposure in cetaceans.

499
Genetically diversified but morphologically identical: are cryptic lineages comparably sensitive?
M. Bundschuh, Institute for Environmental Sciences University of Koblenz-Landau / Department of Aquatic Sciences and Assessment; A. Feckler, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; J.P. Zubrod, A. Thielsch, K. Schwenk, R. Schulz, University of Koblenz-Landau / Institute for Environmental Sciences
Ecotoxicology assumes that traits of individual species (such as sensitivity) only vary around one mean value. However, this assumption may not be applicable in the case of genetically distinct but morphologically identical lineages within nominal species (i.e., cryptic lineage complexes). This is because of a genetic differentiation among lineages comparable to an interspecific level and thus distinctly evolved biological traits that may influence lineages' response to environmental change. Thus, any generalization about cryptic lineages' traits on the basis of only one assessed lineage may be questioned. Hence, we tested whether two cryptic lineages – namely lineages A and B – of the freshwater amphipod *Gammarus fossarum* (Koch) differ in their sensitivity towards chemical stress using the fungicide tebuconazole (up to 600 μg/L), the insecticide thiacloprid (up to 50 μg/L), and ammonia (up to 1.3 mg/L) as model stressors. Gammarids were exposed individually towards the stressors (n=15-20) for 5 to 7 days, while their feeding rate on leaf discs was used as a measure of sensitivity. Results showed a biologically meaningful and statistically significant higher sensitivity towards chemical stress for individuals of cryptic lineage A compared to their counterparts of cryptic lineage B. The extent of sensitivity-differences between lineages was dependent on the type of stressor, with an up to six-fold and two-fold higher sensitivity of cryptic lineage A when applying pesticides and ammonia, respectively. Potential confounding factors that could have influenced the outcome of the studies, such as the season of collection, gammarids' life stage, parasitism, and physiological fitness as well as the upstream land-use patterns at the sampling sites, either were actively controlled for or showed only minor deviations between the assessed lineages. Consequently, the trait differences observed in our studies were most likely explained by the considerable genetic differentiation between the assessed cryptic lineages. Although we only concentrated on one single trait (i.e., sensitivity), our studies indicate meaningful implications in the reliability and quality of environmental monitoring and ecological risk assessment, if cryptic lineage complexes – also reported for standard test species such as *Lumbriculus variegatus*, *Eisenia fetida*, and *Hyalella azteca* – are ignored.

Improving Decision Support for Sustainability Going beyond Standard LCA (III)

500
The Food Loss and Waste (FLW) Value Calculator: addressing challenges in the interpretation of nutrition and environmental impacts of FLW to improve decision support
A. Ernstoff, Quantis / Quantitative Sustainability Assessment; B. De Roo, Cargill; C. Brown, Olam; D. Somogyi, WBCSD; S. Humbert, Quantis
The FAO estimates over 30% of produced food is lost or wasted -- never reaching the mouths of consumers. Food Loss and Waste (FLW) thus poses a massive food system sustainability issue as well as a nutrition and food security issue. Questions remain however regarding how in practice FLW should be addressed in order to improve food system sustainability and food security. There are a variety of decisions that can be made by various stakeholders, for example: reducing or tailoring food production, applying business solutions to reduce food loss and waste at various stages across the value chain, donating to food banks, upcycling or reusing wasted food for different industrial purposes. In order to aid decision-support Quantis sustainability consultants created the Food Loss and Waste Value Calculator. The Calculator was released in its beta version in October 2018, by means of the support of the Food Reform for Sustainability and Health (FReSH) program of the World Business Council for Sustainable Development (WBCSD), and close collaboration with the World Resources Institute (WRI). The purpose of the Calculator is to quickly screen the impacts of food loss and waste with respect to its environmental impacts and nutrition in order to support science-based decision making. Through interactions with various entities regarding the calculator, major challenges regarding the interpretation of FLW impacts have emerged. For example, if feeding FLW to animals creates an environmental impact offset, how should this be interpreted? In this presentation we will discuss the practice of addressing the challenges of interpreting the impact of FLW and the implications for decision support in various contexts.

501
Environmental impact variability of French organic wheat
L. Nitschelm, INRA-Agrocampus Ouest / UMR SAS; A. Tailleur, ARVALIS - Institut du végétal; H.M. Van der Werf, INRA / UMR SAS, INRA, AGROCAMPUS OUEST, Rennes
Studying agricultural systems in LCA often comes with the question of studying variability. Agricultural production systems are usually more diversified than other production systems because of a wide variety of (1) farming practices and (2) emissions which vary depending on the local context. Identifying a representative system at a large geographical scale (e.g., a country) is therefore difficult. AGRIBALYSE is a database of Life Cycle Inventories (LCIs) of the main French agricultural products at the farm gate. Its first version contains mainly representative LCIs of French conventional agricultural systems. Creating these LCIs required compromises in data collection and emissions modelling. We are now creating LCIs of French organic agricultural systems for AGRIBALYSE. Compared to conventional systems, organic systems tend to have more diverse farming practices and depend more on soil and climate conditions as they do not use synthetic inputs. In the project "ACV Bio", we are attempting to capture the diversity of these systems. In this study, we explore the variability in environmental impacts of 18 organic wheat crops that differ in farming practices (e.g., cropping systems, fertilisation, tillage) and local context (e.g. location, soil production potential). Emissions were estimated using models recommended by the AGRIBALYSE database and calculated using the MEANS-InOut tool. We used the characterisation methods ILCD 2011 Midpoint v1.09 and Cumulative Energy Demand (CED) v1.09 to calculate midpoint impacts. PCA and HCPC were then performed as a function of 6 practice-related variables and 7 impact-

related variables. Practice-related variables were place in the cropping system (CS), duration of the CS (years), yield (t DM/ha/yr), total nitrogen (N) input (kg N /ha/yr), tillage operations (number) and ploughing operations (number). The preliminary results suggest that (1) the longer the duration of the CS, the lower the freshwater eutrophication and ecotoxicity impacts, and (2) the higher the yield, the lower the climate change, acidification, marine eutrophication, land use and CED impacts. We are currently assessing the variability in impacts of individual crops and CS per ha of land occupied. Moreover, other impact categories such as biodiversity or human toxicity should be added to better assess the variability in impacts of French organic agriculture. Overall results will be used to identify options to reduce impacts of these crops and systems.

502
Evaluation of plant protection strategies with LCA and risk assessment for five crops in Switzerland
M. Mathis, Agroscope; T. Waldvogel, Agroscope / Institute of Sustainability Sciences; C. Haupt, Agroscope; L. de Baan, Agroscope / Institute for Plant Production Sciences IPS; T. Nemecek, Agroscope / Agroecology and Environment
The use of pesticides is increasingly debated due to unwanted side-effects on humans and the environment. To inform farmers how to reduce such side-effects, comparative assessments of risks and environmental impacts of different crop protection strategies are required. In the present study, crop protection scenarios with different treatment intensity (LOW, MEAN, HIGH) were analysed for five crops in Switzerland: rape seed, wheat, carrots, potatoes, and sugar beets. The MEAN and HIGH crop protection are based on the 50th and 75th percentile of the treatment frequency per pesticide category using a dataset from the Swiss agricultural environmental monitoring, while the LOW scenario represents a reduced treatment frequency, according to the guidelines of the label organization IP-SUISSE. The analysis was conducted with Life cycle assessment (LCA) and risk assessment (RA) method in parallel. LCA assesses average long-term impacts over the whole life cycle, while RA focuses on maximum effects in the short-term, which are site- and context-specific. For LCA, the transfer of pesticides into different environmental compartments was modelled with the model PestLCI. The aquatic and terrestrial ecotoxicity were assessed with USEtox V2.02 and ReCiPe 2016, respectively. The analysis of the LCA results was carried out in two steps: first, only the impacts of pesticides were analysed for the cultivation of 1 ha of crop, in order to ensure a comparability with RA results. Second, a full LCA was conducted (functional unit 1 kg fresh product), including the entire life cycle of the crop. The RA was conducted with the model SYNOPS. It allows a comparative evaluation of overall risks to the field-adjacent local environments and can be used for assessing individual treatments as well as entire treatment sequences. This study showed that a considerable reduction potential exists for pesticide treatment patterns, particularly for the situation with high treatment frequency. Only one or a few active ingredients dominated ecotoxicity impacts and risks. Avoiding these dominating active ingredients seems to be promising for mitigating ecotoxicological impacts. Furthermore, the study showed that it is necessary to consider all relevant environmental compartments and not to focus on water bodies alone. The parallel analysis of environmental impacts (LCA) and risks to the environment (RA) provided a more complete assessment and allows for a robust decision support.

Geolocated Life Cycle Assessment modeling to evaluate the environmental performance of emerging renewable energy technologies: Application to floating offshore wind farms
P. Pérez-Lopéz, MINES ParisTech-PSL / Centre Observation Impacts Energy O.I.E.; B. Poujol, ENGIE Green, Business Unit France Renouvelables; J. Dubranna, MINES ParisTech-PSL / Centre Observation, Impacts, Energie (O.I.E.); A. Prieur-Vernat, ENGIE Lab Crigen; R. Besseau, MINES ParisTech-PSL / Centre Observation, Impacts, Energie (OIE); I. Blanc, MINES ParisTech-PSL / Centre Observation Impacts Energy O.I.E.
The large-scale development of renewable energy systems (RES) to satisfy the increasing energy demand and replace non-renewable fossil sources while reducing the environmental impact represents a major challenge from both socio-economic and environmental perspectives. Although RES are expected to have low resource consumption and pollutant emissions during the electricity production phase, manufacturing and end-of-life phases should be accounted for to ensure their environmental benefits compared to other energy systems. In this study, we propose the use of a geolocated Life Cycle Assessment (LCA) to evaluate the environmental performance of emerging RES. The approach is applied to a pilot project of a floating offshore wind farm to be installed in the Mediterranean Sea. Since the environmental performance of RES is generally expressed as the ratio of the total impact of the technology over its life cycle to the corresponding electricity production, accurate estimates of both terms are essential for a reliable LCA. The total environmental impact over the RES life cycle strongly depends on the quality of data collected during the inventory phase. In this work, the material flows were mainly provided by direct measures from the project suppliers, which ensure the reliability of input data for the model. However, even if the total impacts are based on high-quality inventory data, the environmental performance can be to a large extent affected by uncertainties related to the electricity production. In the case of emerging RES, estimating this production may be particularly challenging due to the absence of historical data for existing installations, especially when dealing with variable resources such as wind or solar irradiation. For such systems, we have developed an approach that consists in parameterizing the electricity production component of the LCA model and coupling this parameterized model to existing geolocated meteorological databases to estimate the RES environmental performance in different locations before its installation. The proposed approach was applied to the floating offshore wind farm 1)to compute the environmental performance of the system accounting for the geolocated electricity production and 2)to identify the main parameters contributing to the evaluated impact categories. Additional sensitivity analyses showed the critical role of the lifetime and the wind data source as the main parameters influencing the environmental results.

505
Emissions of electric vehicle charging in Europe in future scenarios: The effects of time of charging
A.A. Arvesen, S. Völler, C. Hung, Norwegian University of Science and Technology; V. Krey, International Institute for Applied Systems Analysis; A. Strømman, NTNU The Norwegian University of Science and Technology / Energy and Process Engineering Industrial Ecology Programme; M. Korpås, Norwegian University of Science and Technology
Switching from petroleum-burning vehicles to electric vehicles powered by climate-friendly electricity is an important strategy to stabilize the climate. Understanding the current and future emissions associated electric vehicle charging is a key component to formulating effective electric vehicle strategies. At the same time, developing such an understanding is a challenge: Among other things, this is because of the the location- and time-specific character of both electricity generation and vehicle charging, and to uncertainty surrounding future electricity generation mixes. The importance of time can be expected to increase in the future as electricity generation from variable and weather-dependent energy sources (i.e., wind and solar) increases. Here, we use a computer modelling approach in order to elucidate the effects of charging time (time of day) on the greenhouse gas emissions of electric vehicle charging. To do so, we combine climate stabilization scenarios that describe long-term evolutions and aggregated characteristics of power systems, detailed power system modelling that determines energy balances (supply, consumption, trade, losses) at an hourly time resolution, and future-oriented life cycle analyses that quantify direct and indirect emissions of electricity. We investigate three hypothetical charging profiles for electric vehicles, namely fixed charging, workplace charging and home charging. We explore a range of electricity generation scenarios that rely with different degrees on wind, solar, nuclear and natural gas energy. We investigate questions such as: What are the emissions of electric vehicle charging in future scenarios for Europe? How do the emissions vary depending on time of charging (time of day) and country? Does the consideration of time of charging increase or decrease emissions estimates, compared with quantifications that do not consider time of charging? What combinations of electricity mixes and vehicle charging profiles yield the lowest emissions footprints of charging? How do results differ depending on whether average or marginal emissions from electricity are used? Finally, what are the emissions reduction opportunities of 'smart' charging regimes, such as charging at daytime when solar electricity generation is at a maximum? Results, discussion and conclusions will be available for the conference.

Gender Bias and Equal Opportunity in Scientific Research

506
Promoting equality in research organizations: lessons from the Baltic Gender project
H. Valve, Finnish Environment Institute / Environmental Policy Centre
In the field of environmental policy and science, heterogeneity and the inclusion of diverse competences is essential. This is one reason why there is urgent need for the removal of discriminative barriers in academia. In part, the discriminative barriers have to do with gender and with the capacities of women to have an impact on research. The on-going Baltic Gender project (Horizon 2020) approaches these barriers from several perspectives. It recognizes that the lack of family-friendly arrangements, unbalanced research networks, unwritten norms and established routines can, among others, produce and maintain inequality. As a male dominated field, marine science and innovation provides a fruitful context for the development and testing of good practices. In my presentation I will share findings and experiences from the project. The key aim is to initiate discussion about the relevance of the lessons for the SETAC community and get feedback to the proposed measures and approaches. The focus will be on two topics and

working areas in particular. First, I will present findings about the promotion of structural change in the research institutions participating in the Baltic gender project. Best practice measures identified by Kiel University point to the innovative means by which women's academic careers and participation in academic decision-making can be promoted. In the second part I will address the integration of gender in the content of marine research. The very practicing of science can matter for gender equality. In the Baltic Gender project, a method protocol is being produced to support researchers to analyze how their projects link to gender and to promotion of gender equality.

507

Gender bias, publishing, and SETAC

J. Lynch, T.H. Schlekat, SETAC

The focus of this talk will be on three forms of gender bias experienced by women while publishing their research: reviewer bias, authorship bias, and citation bias. We will share personal accounts of perceived bias in publishing from SETAC members and strive to determine whether these are merely anecdotal or indicative of a more pervasive issue. We will review the literature on gender bias in scientific publishing and examine the data from the SETAC publication outlets *Environmental Toxicology and Chemistry* (ET&C) and *Integrated Environmental Assessment and Management* (IEAM) to evaluate if they support the narratives. Using the information gathered, we will report on and propose solutions, where appropriate, to help overcome bias against women with regards to publishing in the scientific fields in general, and more specifically in SETAC journals. The review of the literature indicates that large scale reviewer surveys, such as the recently published Publons 2018 Global State of Peer Review, have found that women are underrepresented in peer review. Women account for less than a quarter (22%) of peer-reviewers registered with Publons, a peer-review recognition website with over 515,000 researchers, and a recent analysis by the American Geophysical Union showed that male authors recommended women reviewers 18% of the time, while male editors recommended women reviewers only 16% of the time. Further, the literature shows disequilibrium in gender ratios among authors who contributed equally and suggests that inequities in credit sharing may be a contributing factor to the continuing gender imbalances reported for academic positions, grant funding, and awards. Preliminary interviews with SETAC members reflect suspected gender-bias in publishing, though not necessarily in SETAC journals. A review of the editorial composition at the journals shows that the current ratio of male to female senior-level editors at ET&C and IEAM are 4:1 and 3:1, respectively. However, preliminary publication data from 2014–2018 indicates that female first authors at ET&C are on par with, and may exceed, male first authors. The talk will report final results based on publication data through the end of 2018.

508

Old and New Faces of Gender and Diversity Bias in Science

M.L. Diamond, University of Toronto / Department of Earth Sciences; A.O. De Silva, Environment and Climate Change Canada

"Its as if I didn't exist – he looked right past me even though I was chairing the meeting". "His comments and actions made me feel uncomfortable but I found it difficult to respond in a way that protected my dignity". In this paper and discussion, we explore some of the multi-facetted experiences of women in environmental science and in academia. The statistics of women's participation in the academy, at least in Canada, paint a positive picture. Women now dominate the graduates of numerous science and a few applied science programs. Women comprise 40% of full-time academic teaching staff in Canadian universities which is an increase since 2010. The salary gap is narrowing, with median female faculty earning 12 vs 25% less than that of their male counterparts in 1990 vs 2016, with the gap depending on rank. Most women experience no or minimal gender bias as they move through undergraduate and graduate school. However, statistics on women's participation continue to fit the "scissor" effect of attrition through the ranks. Of concern is that visible minorities and people of colour constitute only 21 and 2% of all faculty in Canadian universities, respectively. Women of colour have reported disproportionately higher difficulty in achieving insider status, receiving effective mentorship, and building a collaboration network. They also report higher rates of experiencing cultural alienation and a greater accumulation of disadvantage and under-estimation of performance. For about 20 years women chemists at SETAC North America have been meeting to share our accomplishments and challenges. We have built a women's network that helps junior to senior women advance our careers through mentorship and other supports. We share our experience with this network and other actions that we have taken to make environmental science welcoming for all.

Environmental Monitoring and Risk Assessment of UV Filters in Aquatic Environments

510

Concentration of organic UV filters in surface seawater, coral tissue (Porites spp.) and sediment samples from Oahu, Hawaii

C.L. Mitchelmore, University of Maryland / Chesapeake Biological Laboratory; K. He, University of Maryland, Baltimore county / Chemical, Biochemical & Environmental Engineering; E. Hain, University of Maryland Baltimore County / Department of Chemical Biochemical and Environmental Engineering; A. Feerick, University of Maryland Baltimore County; R. Younger, UMCES-CBL; A. Heyes, University of Maryland; M. Gonsior, University of Maryland / Chesapeake Biological Laboratory; A. Conway, UMCES-CBL; L. Blaney, University of Maryland Baltimore County / Department of Chemical Biochemical and Environmental Engineering

Concerns over the toxicity to corals of some organic UV filters contained in sunscreen products resulted in the banning of oxybenzone (BP-3) and 2-Ethylhexyl 4-methoxycinnamate (EHMC or octinoxate) in Hawaii, USA. However, limited or no information is available on the environmental concentrations of these chemicals in seawater, sediment and coral tissue from Hawaiian coral reefs. To address these knowledge gaps surface seawater, coral tissue (*Porites* spp.) and sediment samples from multiple sites (n=29) in Oahu, Hawaii were analyzed for 13 organic UV filters. Surface seawater and sediment samples were collected from a variety of State Parks around Oahu, including Hanauma Bay. A more detailed study of the concentrations of UV filters in seawater, sediment and coral tissue was focused at Waikiki Beach (popular tourist destination), Kaneohe Bay and Ka'a'awa (chosen as a 'reference' location). UV-filters were measured using LC-ESI-MS/MS techniques. Up to nine UV filters were detected in seawater and sediment and up to eight detected in coral tissue samples, although there was no correlation between the concentration of UV filters detected in each environment matrix. The highest detection frequencies and concentrations of UV filters in all matrices was homosalate (HMS), octisalate (OS), BP-3 and octocrylene (OC) although their concentration order depended on the matrix. BP-3 was ubiquitous in surface seawater as it was detected at all sites with the highest concentrations found in the late afternoon samples from Hanauma Bay, Waikiki Beach and Ko'Olina Beach Park, however, at 15 of the 29 sites, aqueous concentrations were less than 10 ng L^{-1}. Similarly, BP-3 was detected in all coral tissue samples at concentrations of 17-265 ng g^{-1} (dry weight, dw.). However, BP-3 was only measurable in sediment samples at 16 out of 29 sites at < 4 ng g^{-1} (dw.). No quantifiable levels of EHMC were recorded for the seawater or coral samples, although OCX was quantified in sediment samples from Kaneohe Bay at concentrations less than 13 ng g^{-1} (dw.). This study provides insight as to the environmentally relevant concentrations in seawater and sediment in Hawaiian coral reef locations. In addition, this study is the first to report concentrations of UV-filters in corals from the USA. These data provide an important baseline for future risk assessments of the potential toxicological effects of UV-filters on coral reefs and other marine organisms in Oahu, Hawaii.

511

UV filters: can we estimate the risk to coral reef?

V. Poulsen, LOREAL / Environmental Safety; M. Leonard, J. Fel, LOREAL / Environmental Research; S. Mezzache, LOREAL / Chemical Analysis

UV filters used in cosmetics are currently under scrutiny due to published papers relating their toxicity towards coral and their potential impact on coral reef bleaching. It is recognised by experts that the cause of coral bleaching is multifactorial, mainly due to global warming, overfishing, and marine pollution. Conscient of the its role and responsabilities, L'Oréal developed, in collaboration with the Monaco Scientific Center, a test on coral nubbins of the species *Styllophora pistillata* to assess the impact of UV filters, and derived NOEC values after a 5-week exposure. When comparing these values to published monitoring data in marine environment in coral reef areas, the obtained ratios show a margin of safety between 692 and 1963 for oxybenzone, and more than 119000 for octocrylene. Avobenzone was not detected in marine water. When comparing these ratios to assessment factors that are usually used in regulatory risk assessment (e.g. 1000 for acute toxicity and 100 for chronic toxicity in REACh regulation), this allows to conclude on negligible risk for coral reefs for octocrylene and avobenzone, and moderate to low risk for oxybenzone. For the other UV filters, there is either a lack of effect data or a lack of measured environmental concentrations to derive these ratios and conclude of potential risk to coral reef.

512

Ecotoxicology of mineral-based sunscreens on reef-building corals

A. Tagliati, Heriot Watt University / Institute of Life and Earth Sciences; S.J. Hennige, The University of Edinburgh / School of Geosciences; T.F. Fernandes, Heriot-Watt University / Centre for Marine Biodiversity and Biotechnology, Institute of Life and Earth Sciences; J. Labille, CNRS; L. Hedouin, CNRS CRIOBE

While several studies have recently demonstrated the toxicity of *chemical* sunscreen compounds on tropical corals, the impact of *mineral* sunscreens and the other core ingredients in sunscreen that constitute the oil phase (emulsifiers and emollients), have not yet been studied. Here we present an integrated view of the effects of custom-made sunscreen lotions, differing in the type of emulsifier ingredients and titanium dioxide nanoparticles ($nTiO_2$) used as UV filters, on the sea anemone *Exaiptasia pallida* (a coral model organism), and early-life stages and mature corals, to identify the sunscreen compounds having the least harmful effects. Sea anemones photosynthetic activity and heat shock proteins (HSP70, HSP90) gene expression were investigated, along with coral respiration, photosynthetic efficiency, symbiont density, chlorophyll a concentrations, gamete fertilization success and larvae survival at multiple timepoints. Coral respiration and net photosynthesis are impacted by sunscreen released in seawater, but sunscreen toxicity does not depend on the action of UV filters alone. Sea anemones showed a negative impact on their photosynthetic activity even when exposed to filter free formulations, indicating that the sunscreen oil phase is also responsible of the observed toxicity. Indeed, gametes exposed to sunscreen formulated with an organic emulsifier (cellulose nanocrystal) showed a reduction in abnormally developed embryos. Results from the present study highlight the importance of taking into account emollient and emulsifier ingredients, in addition to UV filters, when assessing the toxicity of sunscreen products and are promising in identifying the least toxic cosmetic ingredients in order to develop environmentally friendly sunscreens.

513

NanoScreen - Minimizing the risk associated with nanomaterials used in sunscreen at all lifecycle stages

R. Catalano, CEREGE; J. Labille, CNRS; A. Pinsino, IBIM CNR Palermo; S. Robert, CNRS ESPACE; M. Zerrad, Institut Fresnel - Aix Marseille Université; A. Alijagic, Università degli Studi di Palermo; D. Slomberg, CNRS; O. Radakovitch, IRSN

Among cosmetics and personal care products, sunscreen products are of emerging concern regarding both environmental and human healths. While some organic UV blockers have been evidenced to undergo rapid photodegradation, to induce allergene skin reactions due to dermal penetration, or to cause deleterious effects on marine system, the fate of mineral UV blockers is still under consideration from a regulatory perspective. This is largely related to the potential impact of nanotechnology-based products on both environment and human health. The nano-TiO_2UV-blockers typically used in sunscreen usually consist of rutile nanoparticles coated with a first mineral layer of silica or alumina aimed at blocking the photocatalytic character, and thus passivating the nanomaterial. In addition, the grafting of a second layer of organic coating is aimed at favoring the nanomaterial dispersion in the cream formulation. Once drained from the skin either through bathing activity or everyday usage and cleaning, the nanomaterials contained in the susncreen can be released to the sea shore. Their behavior in this system is largely determined by this industrial coating and by their initial dispersion in the formulation. This project aims to develop the Eco-design of sunscreens through the minimization of risks associated with nanomaterials incorporated into the formulation. The release and the impact on the marine environment are mainly considered and studied using the following approaches. In order to estimate the release of nanomaterials from sunscreen in marine environment and the subsequent bioaccessibility and exposition to the living organism, we carried a field campaign on three beaches on the french coast. The titanium concentration was measured in the sea water as a fuction of the number of swimmers. The impact on marine living organism is taken in count by toxicological tests on the sea urchin (Paracentrotus lividus) used as a biological model. In particular, the impact on the sea urchin's immune system (cell viability and toxicity) and reproductive system (embryos development) was evaluated, exposing them to different TiO_2based sunscreen UV filters concentrations. The impact of TiO_2NPs/Oil emulsions on this biological model was also considered.

514

Evaluating the ecotoxic versus beneficial effects of Benzophenone-type UV filters using in vivo and in vitro bioassays

E. Thia; P. Chen, National Taiwan University / Agricultural Chemistry

Benzophenone derivatives (BPs) have been widely used as active ingredients in chemical sunscreens, serving as UV filters which help protect the skin from excessive exposure to sunlight. However, recent studies show that BP-type UV filters (e.g. BP-3) give rise to allergic reactions to mammals and toxic effects to non-targeted organisms. Hence, it is crucial to analyse the toxicity of benzophenone-class UV filters. In this study, several commonly used BPs were first screened for their acute and sublethal toxicities. Medaka (*Oryzias latipes*) larvae were observed over a 96-hour period to determine the acute toxicity of different BPs. Based on LC_{50} data of these compounds, BP-2 was the least toxic among all, followed by BP-3, BP-6, BP-1 and BP-8. Next, the sublethal toxicity was assessed by observing the swimming behaviour of fish larvae. After 24 h exposure, medaka larvae showed no significant difference in the locomotor activity for BP-2, BP-3 and BP-1. In contrast, BP-8 significantly altered the larval locomotion after exposure. This study further evaluated the potential of BPs in inhibiting tyrosinase activity, in addition to their abilities in filtering UV. The whitening potential of BPs was assessed with *in vitro* mushroom tyrosinase assay, using kojic acid as a positive control. Among the BPs evaluated at various tested concentrations, BP-1, BP-3, BP-6 and BP-8 did not show inhibitory effect to tyrosinase enzyme. On the contrary, BP-2 showed an inhibitory effect to mushroom tyrosinase in a dose-dependent manner. Overall, this study indicated that BP-2 was the least toxic compound among all the tested BPs. In addition, BP-2 also showed a promising tyrosinase inhibition activity and may potentially be utilized as a whitening agent. We will further screen the toxicities of more BPs that are commonly used in cosmeceuticals under environmentally-relevant concentrations and continue to investigate the tyrosinase inhibition potential of these BPs using *in vivo* zebrafish (*Danio rerio*) bioassays.

515

Using Eco-epidemiology to Assess the Potential Risks of UV Filters to Corals

S.D. Dyer, Procter & Gamble Company / Environmental Stewardship and Sustainability Organization; C.M. Holmes, Applied Analysis Solutions, LLC; I. Davies, Personal Care Products Council / Science; C. Mitchelmore, UMCES / Chesapeake Biological Laboratory

A recent study in Archives of Environmental Contamination and Toxicology (Downs et al 2016) indicating potential ecotoxicity issues for coral exposed to UV filters, such as benzophenone-3, has gained a global-level of visibility. This single study has provided laboratory evidence that calls into question the sufficiency of environmental risk assessments associated with benzophenone-3 via sunscreen use, particularly for swimmers and sunbathers. For sub-tropical and tropical climates, the potential occurrence for exposure of BP-3 may be year-around. Spatial coincidence of BP-3 exposure and marine ecosystems highly dependent on corals amplifies the potential issues highlighted in the Downs et al study. However, coral reefs have been shown to be adversely affected by numerous other chemical, biological and physical stressors, ranging from local to global scales. Hence, the protection of corals requires a multi-faceted approach that considers not only potential chemicals stressors, but physical stress – including temperature and changes in habitat quality. We advocate the use of eco-epidemiology to evaluate the relationships between environmental stressors and ecological status within a realistic ecological context. This approach supports the recognition that ecosystem status is driven by a multitude of physical, chemical and other environmental factors. Since the foundation of the evaluation relies on measured ecological status, recommendations from such an assessment have great potential for decision-making (including regulations) that will yield fruitful management actions. Our initial analysis utilizes data obtained from experts at the University of Hawaii (e.g., Coral Reef Assessment and Monitoring Program (CRAMP) http://cramp.wcc.hawaii.edu/default.htm). Measured UV filter and surrogate exposure data were collected for the island of Oahu from Mitchelmore et al (2018). To date, published works by the CRAMP experts indicate that both natural and anthropogenic factors may influence coral cover and species richness. Importantly, no single factor has been found to serve as a proxy for coral cover. Hence, it is clear that coral cover and species richness is dependent upon many factors. Based on CRAMP data alone, there appears to be a lack of data supporting the hypothesis that UV filters provide an adverse influence on corals. Our study places into context UV filters amongst several physical and chemical factors that potentially affect coral community health.

Applications of Bayesian Network Models for Environmental Risk Assessment and Management

516

Quantification of AOP by Bayesian network modelling: linking chemical stress to adverse outcomes in Lemna minor

J. Moe, Norwegian Institute for Water Research (NIVA) / Section for Ecotoxicology and Risk Assessment; W.G. Landis, Western Washington University / Institute of Environmental Toxicology; L. Xie, NIVA - Norwegian Institute for Water Research / Environmental Toxicology; K. Tollefsen, NIVA / Ecotoxicology and Risk Assessment; N. Kotamäki, Finnish Environment Institute SYKE; Y. Song, Norwegian Institute for Water Research (NIVA) / Ecotoxicology and Risk Assessment

Although AOPs has gained international recognition as a systematic approach for capturing existing toxicological knowledge to transparently link mechanistic data to toxicity endpoints, most AOPs are not appropriate for quantitative risk assessment. Quantitative AOPs (qAOP) should define the relationships underlying transition from one KE to the next sufficiently well to allow quantitative prediction of the probability or severity of the AO occurring for a given activation of the MIE. We have started developing a Bayesian Network (BN) model to quantify a recently proposed AOP, which links the mode of action of the model respiratory and photosynthesis uncoupler 3,5-dichlorophenol (DCP) to adverse outcomes in the aquatic plant *Lemna minor*. The BN model is based on data from a laboratory experiment exposing *L. minor* to DCP in 8 concentrations with 3 repeated measurements. The measured response variables include OXPHOS (oxidative phosphorylation), ROS (reactive oxygen species), ETR (electron transfer rate), Fv/Fm (maximum quantum yield of photosystem II), LPO (lipid peroxidation) and number of fronds (leaves). The proposed AOP is a network consisting of three chains with the same chemical stressor (DCP) and AO (fronds number). All AOP components were quantified by discrete probability distribution. The causal links (Key Event Relationships) were quantified as conditional probability tables (CPTs), which determine the probability distribution of a child node conditionally on the probability distribution of the parent node(s). The CPTs were quantified by statistical modelling (dose-response curves) of the experimental data and subsequent simulation of response vaules using the estimated parameters and their uncertainty. The quantified AOP-BN model can be used to predict the probability of an adverse outcome (e.g., the probability of fronds no. below a given threshold) for a given level of the stressor, or for a given state of an MIE or a KE. Moreover, the model can be run diagnostically (backwards) to assess, for example, the most likely range of stressor levels that will cause a specified level of an adverse outcome. Future development of this AOP-BN model can include linking the AO to a population-level endpoint with regulatory relevance, and linking the chemical stressor to an Aggregate Exposure Pathway.

517
Integrating Climate Change Stressors and Human Health and Wellbeing into Bayesian Network Relative Risk Model of the Skagit River Watershed
E. Lawerence, Western Washington University / Institute of Environmental Toxicology; L.P. Lackey, Whatcom Community College / Chemistry/Engineering; A.J. Markiewicz, W.G. Landis, Western Washington University / Institute of Environmental Toxicology
Climate change is expected to have widespread impacts on ecosystem services in the Salish Sea. In this research, we focused on the question of how stressors generated by climate change affect contaminant toxicity to species in the Skagit River watershed. Specifically we assessed how those combined effects potentially influence risks to the river's ecosystem services that, in turn, impact human health and well-being. To answer this question, we conducted an ecological risk assessment using the Bayesian network relative risk model (BN-RRM). It is a quantitative, probability-based model that calculates complex relationships between ecological variables to provide estimates of risk to valued receptors (endpoints). We incorporated two main stressor pathways: first, water temperature and dissolved oxygen to represent physical parameters that are influenced by climate change and, second, organophosphate pesticides to represent chemical toxicity and to allow for potential interaction effects between climate and chemical stressors. We focused on Chinook salmon (*Oncorhynchus tshawytscha)* population as an ecosystem service to connect pathways from environmental stressors to human health and well-being endpoints such as human well-being, water quality, salmon fisheries tribal cultural and community health indicators, recreation areas, tourism, boating, and fishing. The BN-RRM enables us to calculate the risks posed by various stressors on these select endpoints in the Skagit River watershed due to climate change. The BN-RRM can also serve as a useful tool for resource managers and decision-makers as part of an adaptive management process and to direct future research efforts in the watershed, as well as in other watersheds in the Salish Sea region.

518
The use of Bayesian networks in adaptive management and constructing resilient systems
W.G. Landis, A.J. Markiewicz, Western Washington University / Institute of Environmental Toxicology
We have described the application of the Bayesian network relative risk model (BN-RRM) in adaptive management. The case study used was the South River RCRA site in the western part of Virginia, USA. Harris et al demonstrated that risk to human well being types of endpoints can be conducted using the same basic techniques. In a new publication, Graham et al applied the BN-RRM approach to estimating risk to water quality and community structure endpoints for a series of estuaries in New South Wales, Australia. The Australian case study took advantage of the extensive dataset derived from years of monitoring and the relatively new method of eDNA to establish the conditional probablites of a set of causal pathways. In both case studies the long-term goal is the ability to manage these sites over multiple decades. In applying risk assessment to adaptive mangment we propose three segments. Segment A describes the social, cultural and regulatory factors that are being used as to bound the decision making as towards goals and resources. Part B is the active part of the process, where the research, risk assessment, engineering monitoring, learning and decision process takes place. Part C is the section that observes and reports on the change in externalities to the adaptive system. Climate change can be an example, so can an increase in population pressure, changes in technology, and any other factor that will alter the implementation of Part B. As demonstrated the BN-RRM structure is easily updated with new information, can incorporate management options, and likelihood of different causes can be calculated. The efforts of monitoring plans can be incorporated and the causes reevaluated as an innate part of the adaptive management process. Resiliance can be explored by by adding additional nodes to describe specific externalities or new management tools. The risk can then be recalcuated and the change compared to the original condition. We have found that such efforts find that not all endpoints are similarly affected. For example a managment scheme to reduce Hg contamination to fish alters breeding habitat for Kingfisher birds. We have demonstrated that is it possible to incorporate a Bayesian network based risk assessment into adaptive management. In this playing of what if games the innate advantages of the Bayesian network format becomes a key to developing management plans and examining how they affect resiliency

519
Ecological risk assessment of multiple flow and non-flow stressors to the Upper Niger River and Inner Niger Delta, West Africa using PROBFLO.
G.C. O'Brien, University of Mpumalanga / School of Life Sciences; C. Dickens, International Water Management Institute
The millions of people who live in the Upper Niger River and Inner Niger Delta depend on its natural resources and ecosystem services for their livelihoods and wellbeing. The availability of water resources of the region is highly variable, driven primarily by the seasonal flows and the associated flooding of the delta. The aim of this study was to use regional socio-ecological information related to the structure, function, use and protection of water resources in the context of regional management targets, to carry out a holistic regional scale ecological risk assessment addressing flow and non-flow stressors using the PROBFLO method. In this study a review of available water resources information from the study area and region was undertaken. With stakeholders of the study area and real hydrological and hydraulic information, the ten procedural steps of PROBFLO were undertaken. The outcomes for all of the development scenarios considered result in low risk probabilities for most social and ecological endpoints considered, except for the maintenance of the mammal endpoints within the detla itself. In addition, the risk to the endpoints in the delta were relatively greater that the risk to the endpoints upstream in the river habitats. The outcomes of this precautionary desktop E-flow assessment include relatively high percentages of the natural water flows ranging from 39% – 63% across the different regions of the upstream basin to sustain the socio-ecological system. Results show that the maximum planned developments in the catchment for a planned development (FUTURE 1) scenario will result in insufficient water in the river during the dry seasons, that would be unacceptable in the context of the vision of the study area. This will have impacts on the design of new dams and irrigation schemes, as water will need to be allocated to maintenance of the E-flows in the dry season. The PROBFLO method was successfully applied in the case study. From these outcomes, stakeholders have, been able to consider sustainable social and ecological trade-offs between, to balance the use and protection of water resources in the study area. And we have provided the initial requirements for E-flows to maintain the socio-ecological sustainability of the water resources in the region. The adaptability of the approach allows for the incorporation of new information rapidly that will inform adaptive management for the management of water resources in the study area.

520
Dioxins in Baltic herring and salmon: an inter-sectoral decision analysis for optimal management of the problem
A. Lehikoinen, University of Helsinki / Ecosystems and Environment Research Programme; P. Haapasaari, University of Helsinki
Ecosystem-based management (EBM) of natural resources requires recognition of the systemic intertwining of ecosystems and human society and an inter-sectoral approach. We used a Bayesian influence diagram to integrate different types of knowledge for evaluating alternative sectoral and inter-sectoral strategies to manage the dioxin problem of Baltic salmon and herring fisheries. The following strategies were evaluated: 1) decreasing dioxin and nutrient loading to the ecosystem, 2) herring and salmon fishing strategies, 3) dietary recommendations, and 4) improved information concerning the benefits of fish eating. In total nine decisions and their combinations were evaluated in the light of three alternative assessment criteria: 1) the dioxin concentrations of Baltic herring and salmon, 2) the human consumption of Baltic salmon and herring, and the associated health risks and benefits, and 3) the commercial value of herring and salmon catches. The results demonstrate the requirement to understand the effects of management measures in a holistic way: managing only one species or policy domain may not be effective, and may also have unanticipated systemic effects in the ecosystem. In general, optimal management depends to some extent on the assessment criteria used, as well as the order in which the decisions are made. Unsynchronized management decisions in different sectors may decrease each other's effectiveness. This implies that to control the dioxin problem as effectively as possible, collaboration between the public health, environmental and fisheries sectors is needed.

521
Need to know and need to act: Value-of-information and value-of-contol in Bayesian decision analysis
S. Kuikka, University of Hesinki / ECOENV research program
Bayesian decision analysis is focusing on the decision making under uncertainty. In here, the Bayesian influence diagrams are commonly used tools. Instead of using deterministic equations and point estimate models, they model the dependencies of variable by using conditional probabilities. This allows a relatively simple integration of e.g. economic, social, biological and juridical information in complex decision tasks. An interesting and important part of a Bayesian model is the possibility to calculate backwards from effects to causes, and thereby carry out diagnostic analysis, where the information contents of

several indicators can be integrated to several, potentially competing, uncertain hypothesis which may be causes for the observable effects, often called indicators in biological diagnostics. The value-of-information (VOI) is a well-known concept in Bayesian decision analysis, as the aim of the decision models is to supports selection of preferable actions. It is an estimate of how much one should, as maximum, allocate to improve the knowledge about the system before the management action is carried out. Management action aims to improve the state of the system, whereas the VOI analysis is focused on the improved knowledge. Both aspects are described in one model. The analysis is based on the prior distributions of the knowledge: if this is what I know at the moment (uncertain knowledge described by probability distributions), is there a possibility that the decision will be changed, if I increase the amount of knowledge? This possibility to learn is described by probability distributions. Surprisingly, the concept of value-of-control is poorly known, and very seldomly applied in current applications of decision analysis. It describes how much more probable it is to reach the objectives (increase the value of objective function) if some of the probabilistic variables are changed to be decision variables, which increases the controllability of the uncertain system, described by the conditional probabilities of the model. It should be in the heart of any management analysis, including the evaluation of how likely it is that a new law leads to desired state of the system, in many cases the behavior of humans. It seems that the VOI and VOC are related: there is no need to know if there is no need to act, or if the controllability of the system is poor. I Keywords: Bayesian, decision analysis, value-of-information, value-of-control

One Health: Interdisciplinary Solutions for Complex Problems

522

One Health: Interdisciplinary solutions for complex problems - topic overview and session goals

T. Augspurger, U.S. Fish and Wildlife Service / Ecological Services

The topic of One Health is in line with SETAC's mission. One Health is a collaborative, multi-sectoral, and trans-disciplinary approach, working locally, regionally, nationally, and globally, to achieve optimal health and well-being of all animals, people, plants and their shared environment, recognizing their inextricable interconnections. SETAC's mission is to support the development of principles and practices for protection, enhancement and management of sustainable environmental quality and ecosystem integrity. The goal of this overall session is to bring the concept of One Health to the SETAC community. In this introductory presentation, we will provide some background on the One Health framework in the context of SETAC, provide a variety of examples from which the audience can draw parallels to their own research, enhance communication between the different niches within SETAC, and provide a forum to have any relevant questions answered by leaders in the One Health field. This context will help set up set the stage for the following invited presentations. Each of the invited presentations highlights One Health from the perspective of each of the four sectors represented within SETAC; academia, government, non-governmental organizations, and business/industry.

523

Advancing integrated holistic approaches for assessment of health and environmental risks within the SETAC scientific community

C. Menzie,

There is great promise in integrating the assessment of human and ecological issues in a manner consistent with One Health. An additional dimension of an integrated approach comes from the social sciences and includes the manner in which risks are perceived and communicated. A holistic view makes sense because environmental decisions are ideally informed by a combination of human health, environmental health, and socioeconomic factors. Considering these in an integrated way rather than as isolated bins of information enables a deeper and more complete understanding of an issue. In particular, identifying the health, ecosystem services, and psychosocial connections between people and their environment yields more complete conceptual models for outlining the nature of an issue. While segmenting the problem into various health and environmental components is necessary for analysis purposes, these segments should flow from explicit recognition that the parts are interrelated. The overall analytical process should track, make use of, and incorporate the interconnections. Many of SETAC's Interest Groups already reflect elements of integrated approaches; a few examples include Ecological Risk Assessment, Human Health, and Ecosystem Services. National and international initiatives have examined how best to integrate human health and ecological risk assessment. The U.S. EPA's Cumulative Risk program seeks to meld human health, ecological and other factors impinging on communities. And, it is evident that an integrated One-Health approach makes sense for developing countries. SETAC members in these countries have pointed to a myriad of health and environmental problems confronting their societies such that a more holistic approach is desired. SETAC together with the Society of Risk Analysis (SRA) is providing an introductory course for the 2019 SETAC Africa meeting that integrates human health and ecological risk assessment. SETAC leadership can make a difference, especially given our inclusive tripartite approach and the deep commitment of scientists in both the developed and developing world who seek collaboration. SETAC is moving forward with global certification for risk assessor. There is great value for risk assessors to develop competence in the full suite of risk factors and human and environmental receptors associated with the issues we are facing. Among these are management of chemicals, introduction of new technologies and products, changes in habitat, availability of clean water, nutrient enrichment, salinization, a host of climate change related alterations, invasive species, and disease. These too are interrelated and consistent with the SETAC Europe meeting theme: One Environment. One Health. Sustainable Societies.

524

Extrapolation of Chemical Susceptibilities Across Humans, Domesticated Animals, Wildlife, and Plants using the SeqAPASS Tool

J. Doering, NRC U.S. EPA / Mid-Continent Ecology Division

Chemicals in the environment can cause health concerns for humans, domesticated animals, wildlife, and plants. However, the health of all organisms of concern cannot be pragmatically evaluated and therefore chemical hazard assessment requires extrapolation of information from model organisms to other species. Therefore, the Sequence Alignment to Predict Across Species Susceptibility (SeqAPASS) tool was developed by the U.S. Environmental Protection Agency (USEPA) as a rapid, cost effective method of species extrapolation of chemical susceptibilities. Specifically, the SeqAPASS tool compares the primary sequence (Level 1), functional domain sequence (Level 2), or individual amino acid residues at key positions (Level 3) of the protein target of a chemical in a species of known susceptibility to sequences of other species in the National Center for Biotechnology Information (NCBI) database. Sequence similarity metrics are then calculated and results at these three levels of comparison can be used as lines of evidence to predict shared chemical susceptibility across species and taxa. Several case studies have been developed demonstrating the utility of SeqAPASS in species extrapolation of susceptibility to pesticides, human and veterinary pharmaceuticals, as well as for extrapolation of data from mammalian-based high-throughput screening assays. This presentation will demonstrate utility of the SeqAPASS tool to the One Health approach. Specifically, this presentation will outline a case study using SeqAPASS to extrapolate susceptibilities to chemicals that interact with the thyroid axis target, thyroid hormone receptor alpha (THRa), from responses measured in a human-based *in vitro* assay used in the Toxicity ForeCaster (ToxCast) program. Level 1 (primary sequence), 2 (functional domain sequence), and 3 (key amino acid position) comparisons in SeqAPASS all suggest that chemicals that interact with THRa of human will interact with THRa of other vertebrates, but susceptibility is unlikely among invertebrates, plants, and other lower organisms. Therefore, health risks posed by THRa active chemicals in humans are predicted to be shared among all vertebrates, including mammals, birds, reptiles, amphibians, and fishes. This case study demonstrates how SeqAPASS can be used toward the One Health objective of linking the health of humans, domesticated animals, wildlife, and plants and provides a rapid, cost effective method of species extrapolation toward this goal.

525

A veterinary perspective on One Health in the Arctic

C. Sonne, Aarhus University AU Arctic Research Centre / Department of Bioscience; R.J. Letcher, Environment and Climate Change Canada / Ecotoxicology and Wildlife Health Division; B. Jenssen, Norwegian University of Science and Technology / Biology; J. Desforges, Aarhus University (AU) / bioscience; I. Eulaers, Aarhus University (AU), Arctic Research Centre / bioscience; E. Andersen-Ranberg, University of Copenhagen; K. Gustavson, Aarhus University; B. Styrishave, Dep. of Pharmaceutics & Analytical Chemistry; R. Dietz, Aarhus University

Exposure to long-range transported industrial chemicals, climate change and diseases is posing a risk to the overall health and populations of Arctic wildlife. Since local communities are relying on the same marine food web as marine mammals in the Arctic, it requires a One Health approach to understand the holistic ecosystem health including that of humans. Here we collect and identify gaps in the current knowledge of health in the Arctic and present the veterinary perspective of One Health and ecosystem dynamics. The review shows that exposure to persistent organic pollutants (POPs) is having multiple organ-system effects across taxa, including impacts on neuroendocrine disruption, immune suppression and decreased bone density among others. Furthermore, the warming Arctic climate is suspected to influence abiotic and biotic long-range transport and exposure pathways of contaminants to the Arctic resulting in increases in POP exposure of both wildlife and human populations. Exposure to vector-borne diseases and zoonoses may increase as well through range expansion and introduction of invasive species. It will be important in the future to investigate the effects of these multiple stressors on wildlife and local people to better predict the individual-level health risks. It is within this framework that One Health approaches offer promising opportunities to survey and pinpoint environmental changes that have effects on wildlife and human health.

Applying a "One Health" Approach to the Assessment of PFAS: Opportunity to Prevent Unintended Consequences
T. Lopez, J.M. Diamond, Tetra Tech, Inc.; J. Flippin, Tetra Tech, Inc / Center for Ecological Sciences; M. Bowersox, S. Richards, Tetra Tech, Inc
The One Health concept recognizes the interconnected health of the environment, animals and humans and that a transdisciplinary approach can achieve optimal health outcomes by recognizing these interactions. Due to their ubiquitous presence from widespread usage in consumer products, commercial operations, and firefighting, and their environmental persistence, per- and polyfluoroalkylated substances (PFAS) are globally distributed in the environment and detectable levels of PFAS are present in virtually all humans, as well as terrestrial and aquatic animals. Using the One Health concept we evaluate PFAS in the environment through a review of toxicity information, fate and transport information, sampling data, and regulatory efforts. Based on environmental media and biota concentrations observed in our work and others at several sites around the globe, we illustrate likely exposure scenarios for biota and humans, and highlight some of the current challenges in assessing risks of this unique class of chemicals. Information from our research and that of others indicates that potential exposure pathways of PFAS in soils, sediments, and water to animals and plants are complete, and PFAS is transported through the food chain, presenting an additional exposure pathway to humans as well. Fish tissue PFAS data, for example, indicate potential linkages between ecological and human health suggesting that consumption of fish may be a major source of exposure to these chemicals. When combined with potential intakes through drinking water as well as consumer exposures through household items, the possibility exists for much higher intakes and much longer-term exposure than estimated through environmental media alone, or from consumer exposure alone. Using a One Health approach will help provide integrated assessments of PFAS. It will promote discussion of the efficiencies to the business community of a One Health approach to chemical exposure from manufacture and intended use, to environmental release and remediation.

Lancet Commission on Pollution and Health: Findings, One Health Perspectives, and SETAC Opportunities
N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences
Last year the Lancet Commission on Pollution and Health was released. As one of the report co-authors, here I discuss the findings of our work and also examine these through a One Health lens (e.g., parallel research on environmental quality). The Commission addressed the full human health economic costs of air, water, and soil pollution. Stark conclusions were drawn including, for example, pollution is responsible for 9 million premature deaths per year (3-times more than AIDS, malaria, and TB combined), more than 90% of these deaths are released in low- and middle-income countries, and that it may reduce the GDP of countries by up to 2%. Furthermore, these estimates (and many more), likely under-estimate the true costs of pollution owing to tremendous data gaps that remain. The Commission also pointed to several success stories that highlight that solutions and strategies can have co-benefits for the environment, health, and the economy. The Commission focused strictly on human health though similar questions can be asked about environmental quality. Here, as I systematically break down the Commission's report, I will take a One Health approach and provide examples from studies that are concerned with environmental quality and animal health (e.g., how many fish and wildlife prematurely die from exposure to pollution? What are the economic costs of this?). I will conclude with some recommendations for SETAC members based on our experiences with the Lancet Commission.

Chemical Exposure via Plastics and Synthetic Rubbers: Quo Vadimus?

529
Method for comparing the release potential of additives from plastic materials
S. Frattini, European Chemical Agency (ECHA); A. Ahrens, ECHA (European Chemicals Agency) / B4 Exposure and supply chain; H. Piha, European Chemical Agency ECHA; T. Alasuvanto, European Chemicals Agency
The release of hazardous substances from plastic materials is an area of high public interest. During the first two registration deadlines under REACH, several hundred substances potentially used as additives in plastics have been registered in volumes of 100 tonnes/year or more. However, for many of these substances, there is significant uncertainty on the hazards and potential releases from plastic matrices. In late 2016, ECHA and a number of Industry sector organisations have started a joint effort for characterising the uses of the various plastic additives and the corresponding potential for release from articles. This work aims to support: i) industry in improving the REACH registration information on the use of plastic additives and the related exposure potential, and ii) authorities in prioritisation and de-prioritisation of substances for initiation of regulatory processes. The project focuses on approaches and learnings when comparing and ranking the potential of additives to be released from plastic matrials: i) an overview of substances confirmed by industry as plastic additives; ii) development of a robust method to compare the release potential of additives from different plastic matrices; iii) grouping of additives by function and ranking according to their release potential. The presentation explains the method including uncertainties and limitations, and the outcome. Learning and potential follow up is discussed.

530
Chemicals in plastic packaging: Prioritization case studies
K. Groh, B. Geueke, Food Packaging Forum Foundation; T. Backhaus, University of Gothenburg / Department of Biological and Environmental Sciences; B. Carney Almroth, University of Gothenburg Sweden / Department of Biology and Environmental Sciences; P. Inostroza, University of Gothenburg / Department of Biological and Environmental Science; A. Lennquist, Chemsec; D. Slunge, University of Gothenburg / Centre for Sustainable Development; L. Trasande, New York University School of Medicine; A.M. Warhurst, CHEM Trust; M. Maffini, Independent Consultant; J. Muncke, Food Packaging Forum Foundation / General Management
Around 40% of plastics produced globally are used to make packaging. Effective management of plastic packaging should consider not only physical hazards but also chemical safety aspects. Gathering information on the exact chemical composition of plastic packaging can support substitution efforts, but this task is not trivial, as plastic packaging can be made of multiple polymers with numerous additives, along with other components, e.g. adhesives or coatings. We compiled a database of Chemicals associated with Plastic Packaging (CPPdb), covering known chemicals used during manufacturing and/or present in final packaging articles. The current version (https://doi.org/10.5281/zenodo.1287773) lists 902 chemicals likely associated with plasic packaging and 3353 chemicals possibly associated. Based on harmonized health and environmental hazard classifications, 148 chemicals likely associated with plastic packaging were identified as very hazardous. However, the majority of CPPdb chemicals lacked any harmonized hazard information. To identify the most urgent substitution candidates, we performed two prioritization case studies focusing on human health and environmental effects. Importantly, prioritization is a decision tool strongly dependent on expert judgement, and different strategies could result in different priority lists. For environmental hazards, our prioritization steps considered information from ecotoxicological databases and scientific literature, and resulted in the selection of benzyl butyl phthalate (BBP, CAS 85-68-7) as the first candidate for a more detailed assessment. For human health hazards, our prioritization strategy considered biomonitoring data, endocrine disrupting properties, and regulatory requirements in Europe, and resulted in a priority list of five phthalates (BBP; dibutyl phthalate (DBP, CAS 84-74-2); diisobutyl phthalate (DiBP, CAS 84-69-5); bis(2-ethylhexyl) phthalate (DEHP, CAS 117-81-7); dicyclohexyl phthalate (DCHP; CAS 84-61-7)). Identifying and ranking hazardous chemicals associated with plastic packaging is challenged by the lack of transparency on the use and toxicity of numerous substances. Both prioritization case studies focussing on the environment and human health highlighted phthalates as substitution candidates. Despite various restrictions, phthalates are still found in plastic packaging worldwide. The exposure potential likely resulting from this use further justifies the need for targeted substitution efforts.

531
Identification of chemicals in food packaging plastic films by non-targeted analysis
Y. Sapozhnikova, U.S. Food and Drug Administration / ARS; E. Hoh, San Diego State University / School of Public Health
Plastic food packaging is widely used for protecting food from microorganisms and extending its shelf-life, while also providing consumers with convenient food handling. However, known and unknown chemicals from food packaging materials may potentially migrate into packaged food and present a risk to consumers. Plastic stretch film, or cling film, is one of the most widely used food contact materials in commercial and consumer applications. It is also the most complex in structure and composition, constructed with multiple layers and chemical additives to improve the film properties, including antioxidants, light stabilizers, plasticizers, thermal stabilizers, lubricants, antistatic agents, *etc.* Other chemicals: non-intentionally added substances - chemical impurities, contaminants, and chemicals formed during degradation and/or reaction of added chemicals also may be present. The goal of this study was to perform identification of chemicals extracted from food packaging stretch films. The films were extracted with US FDA approved food simulant: water/ethanol, 5%/95%, plus with three organic solvents with different polarities: hexane, ethyl acetate, and acetonitrile, to cover both polar- and relatively non-polar chemicals. Non-targeted GC×GC/TOF-MS analysis based on >70% match similarity to the standard NIST mass spectral library and manual review of mass spectral matching was used for tentative identification. Overall, 64-91 compounds were tentatively

identified, and selective migration was observed for some compounds between different solvents/food simulants. Among these compounds, several classes of chemicals were identified: alkylated naphthalenes used as lubricants, polycyclic aromatic hydrocarbons (PAHs) including those on the US EPA priority pollutant list, plasticizers, polymer additives, UV filters, flavoring agents and fragrances, surfactants, adhesives, products of thermal degradation, and low chlorinated polychlorinated biphenyls (PCBs). The identified compounds were characterized based on use/source, chemical properties, and previously reported occurrences in plastic food packaging materials, food and/or the environment. Several chemicals found in plastic films in our study were not previously reported as migrants from plastic materials by previous studies. Future studies should focus on quantitative migration to estimate the amounts of migrating chemicals into food simulants and real foods to provide data for risk assessment.

532
Wear and Tear of Tyres in the Global Environment: Size Distribution, Emission, Pathways and Health Effects
P.J. Kole, Open University / Science; A.J. Löhr, Open University; F.G. van Belleghem, Open University of The Netherlands; A.M. Ragas, Radbound University / Department of Environmental Science
Wear and tear from tyres significantly contributes to the flow of (micro-)plastics into the environment. Our study compiles the fragmented knowledge on tyre wear and tear characteristics, amounts of particles emitted, pathways in the environment, and the possible effects on humans. The estimated per capita emission ranges from 0.23 to 4.7 kg/year, with a global average of 0.80 kg/year. The emissions from car tyres (100%) are substantially higher than those of other sources of microplastics, e.g., airplane tyres (2%), artificial turf (12–50%), brake wear (8%) and road markings (5%). Emissions and pathways depend on local factors like road type and sewage systems. The contribution of tyre wear and tear to the total global amount of plastics ending up in oceans is estimated to be 5–10%. In air 3–7% of the particulate matter (PM2.5) is estimated to consist of tyre wear and tear, indicating that it may contribute to the global health burden of ambient air pollution which has been projected by the WHO at 4.2 million deaths in 2016 from which 77,550 in the USA and 1,028 in Finland. It is yet unkown how much tyre wear and tear contributes to this death toll, but if it contirubutes relative to its weight fraction, it would be reponsible for 130,000-300,000 annual deaths globally, from which 2,330–5,430 in the USA and 30–70 in Finland. The wear and tear also enters our food chain, but further research is needed to assess potential health risks. Tyre wear and tear remains in the environment for a long time. The degradation half-life in soil is estimated at 490 days and in sediment at 4900 days. Preventing tyre wear and tear from entering the environment on short hand seems infeasible as there currently is no alternative for synthetic rubber. Mitigation should therefore focus on emission reduction, i.e. the development of wear resistant tyres, self-driving cars (less wear), open asphalt concrete roads (capturing wear and tear) and improving sewers and waste water treatment plant efficiency. It is concluded that tyre wear and tear is a stealthy source of microplastics in our environment which can only be addressed effectively if awareness increases, knowledge gaps on quantities and effects are being closed, and creative technical solutions are being sought. This requires a global effort from all stakeholders; consumers, regulators, industry and researchers alike.

533
Microplastics in the terrestrial environment - Impacts of tyre wear particles on soil animals
S.K. Selonen, Vrije Universiteit Amsterdam / Department of Ecological Science; L.N. Sackey, University of Chemistry and Technology / Department of Environmental Chemistry; R. Turja, Finnish Environment Institute, SYKE / Marine Research Centre; C. van Gestel, Vrije Universiteit Amsterdam / Ecological Science
Microplastics, i.e. plastic particles smaller than 5 mm and their potential effects in environment have raised growing public concerns. However, the research on microplastics has mostly been directed to aquatic environments, and their entering and possible effects in terrestrial food webs are poorly known. It has been estimated that tyre wear particles (TWP) are among the most abundant microplastic particles released to environment due to human activities. However, there is still a gap of knowledge on the fate and environmental concentrations as well as the effects of tyre wear particles especially in the terrestrial environment. To shed light on this subject, the effects of TWP with size range of 0-180 μm on the survival and reproduction of the enchytraeid worm *Enchytraeus crypticus* and the springtail *Folsomia candida* as well as survival, growth, reproduction and biochemical biomarkers of the earthworm *Eisenia andrei* were studied. Standard Lufa 2.2 soil (Lufa Speyer, Germany) and/or food were spiked with concentrations of 0.02 %, 0.06 %, 0.17 %, 0.5 % and 1.5 % of TWP in dry mass. Survival and reproduction of the springtail *F. candida* seemed to be affected by TWP, but as the response was not consistent in relation to the concentration in soil or the variation among the replicates, none of the treatments differed significantly from the control. Tyre wear particles in food did not affect enchytraeid worms, but when they were spiked in soil, reproduction slightly increased at the lowest concentration and slightly decreased at the highest concentration when compared to the control. There also seemed to be a slight negative trend in earthworm survival and a positive trend in the change of biomass with increasing TWP concentration, but no statistically significant differences between the treatments were found. The biomarker data have not been analysed yet. Our study shows that tyre wear particles can affect soil animals, but the effects are slight and not always consistently related to the increasing concentration of the particles. As tyre wear particles contain xenobiotics that can be harmful to biota, it is possible that these chemicals can accumulate in the terrestrial food web via ingestion of tyre wear particles by soil animals. This study is part of the project IMPASSE – Impacts of Microplastics in Agro Systems and Stream Environments.

State of the Science on Emerging and Novel Poly- and Perfluoroalkyl Substances (PFASs) (I)

535
Environmental contamination and human exposure to PFAS near a fluorochemical production plant: Review of historic and current PFOA and GenX contamination in the Netherlands
W. Gebbink, PFA Brussels; S. van Leeuwen, RIKILT - Wageningen University & Research / RIKILT
Primary sources of per and polyfluprpalkyl substance (PFAS) emissions into the environment (water and air) are fluorochemical production plants (FPP), and once released into the environment, PFASs distribute to other abiotic media such as soil and sediment and accumulate into biota including in human food chains.A FPP located near the city of Dordrecht in the Netherlands has been producing fluoropolymers since the 1970s by using PFOA in this process until 2012 and GenX from 2013 onward. Over the last decade, peer-reviewed publications and reports have been published on the presence of PFOA in the Dutch environment (including surface, ground and drinking water, soil, vegetation and food), while publications and reports on GenX in these matrices were published mostly in recent years. The aim of this study was to review the contamination of the local environment near the FPP with PFOA and GenX relative to other locations in the Netherlands by using data for multiple environmental matrices published in the peer-reviewed literature as well as in the grey-literature. Besides environmental contamination, this review will also report on contamination of human exposure pathways (drinking water, food) with PFOA and/or GenX on a local and national level. Data were available on PFOA and GenX in surface water, ground water, soil and vegetation. These studies included multiple sampling sites nearby the FPP as well as other locations in the Netherlands. Data on PFOA and GenX in drinking water from numerous locations throughout the Netherlands was available as well as on both PFASs in fruit and vegetables.Preliminary analyses of the available data showed that PFOA has been monitored in surface water yearly since 2006 at several locations, while the earliest reporting of GenX was in 2013 followed by 2016 and 2017.Considerable higher GenX concentrations were found in downstream sampling locations from the FPP compared to other locations in the Netherlands, while this pattern was less clear for PFOA.PFOA and GenX were detected in drinking water mostly in the western part of the Netherlands where also the FPP is located. During the period of 2010 and 2016, PFOA concentrations ranged between 1.4 and 23 ng/L, while during 2016 and 2017, GenX concentrations ranged from 0.3 to 29 ng/L. Data review of PFOA and GenX in groundwater, soil, vegetation and food are ongoing.

536
Evaluation of unknown precursors in paper-fibre biosolids contaminated sites by combination of sum parameters and PFAS analysis
F. Lange, TZW DVGW-Technologiezentrum Wasser; K. Nödler, TZW DVGW-Technologiezentrum Wasser / Analysis and Water Quality department; F. Sacher, TZW DVGW-Technologiezentrum Wasser; M. Scheurer, TZW DVGW-Technologiezentrum Wasser / Analysis and Water Quality; B. Bugsel, S. Tisler, University of Tuebingen / Environmental Analytical Chemistry at the Center for Applied Geosciences; M. Muschket, UFZ- Helmholtz Centre for Environmental Research / Effect-Directed Analysis; C. Zwiener, Environmental Analytical Chemistry, Center for Applied Geoscience, University of Tuebingen / Geosciences; U. Berger, Helmholtz centre for environmental research - UFZ / Analytical Chemistry
In the regions around Rastatt/Baden-Baden and Mannheim in southwest Germany ca. 600 ha of agricultural land is contaminated by per- and polyfluorinated alkyl substances (PFASs). This contamination was predominantly caused by the use of compost, mixed with paper-fibre biosolids, and applied to the fields, tentatively in the period 2000-2008. Besides perfluoroalkyl acids (PFAAs), other compound classes of grease-proofing agents in food-contact materials of paper and board, such as polyfluoroalkyl phosphate esters (PAPs), perfluoroalkane sulfonamidoethanol-based phosphate esters (SAmPAPs), perfluoroalkylpolyethers (PFPEs), and side-chain fluorinated polymers (poly(meth)acrylates, polyurethanes) are either proven or expected to occur in this area. These chemicals

can act as precursors to persistent and mobile PFAAs, which are transferred to groundwater aquifers and drinking water as well as to field crops. To assess the formation potential of mobile intermediates and persistent and mobile terminal products, we compared the results of target analysis for several PFAS classes to the sum parameters (i) extractable organic fluorine (*EOF*) in soil (ii) total oxidisable precursor (*TOP*) assay in soil and crops and (iii) to adsorbable organic fluorine (*AOF*) in aqueous soil leachates. In addition, non-target screening by LC-Q-TOF-MS was used to identify PFAS classes. In surface soils organofluorine levels up to the mg/kg range occurred. Organofluorine of PFASs from target analysis (ΣF(PFASs)) accounted for about 50 % of the EOF. (ΣF(PFASs) correlated well with the EOF in soil samples (r^2=0.99). Precursors were mainly located in the in the plough horizon (upper 40 cm). The maximum of the leachable, mobile fraction, measured as AOF in aqueous soil leachates was located about 10 cm below the plough horizon. Organofluorine of intermediates in soil accounted for 4.3–25 % of ΣF(PFASs). EtFOSAA was the prevailing intermediate with 0.4-18 % of ΣF(PFASs). Only short-chain PFAAs, PFOS, and traces of a few mobile intermediates were transferred to crops (wheat, maize, grass). Non-target screening revealed the occurrence of more than 100 PFASs in 18 homologous series. The precursors 6:2 to 12:2 (and mixed) diPAPs and their possible degradation products were the most abundant PFASs, followed by diSAmPAPs (8 homologues) and the degradation products EtFASAAs and PFOS. Polyfluoropolyethers (PFPEs) have been detected in several homologous series, but at low abundances.

537

Emerging and legacy per- and polyfluoroalkyl substances in surface and deep waters from the North Sea to the Arctic

H. Joerss, Helmholtz-Zentrum Geesthacht / Environmental Chemistry; Z. Xie, R. Ebinghaus, Helmholtz-Zentrum Geesthacht / Department for Environmental Chemistry, Institute of Coastal Research

Long-chain per- and polyfluoroalkyl substances (PFASs) have been shown to be persistent, bioaccumulative, toxic, and to undergo long-range transport. Consequently, an industrial shift has been taking place, moving from long-chain PFASs towards replacement substances, such as per- and polyfluoroether carboxylic and sulfonic acids (PFECAs and PFESAs). Due to structural similarities, the question arises whether the alternatives represent a substantial improvement. For legacy PFASs like PFOS and PFOA, it is known that they reach remote areas and accumulate there. However, experimental data on potential long-range transport of emerging PFASs is still limited. Modeling data suggest that several ether-based alternatives and their common predecessors possess comparable long-range transport potential. In addition, PFECAs and PFESAs have been detected in Europe, China and North America already. Together with first findings in Arctic biota, these data indicate that ether-based replacements can be globally distributed and are likely to undergo long-range transport. This study aims at investigating occurrence and distribution of emerging and legacy PFASs in surface and deep waters along potential transport pathways from the North Sea to the Arctic. 54 surface water samples and 6 vertical profiles from bottom to surface were taken during the *Polarstern* cruise PS114 in July 2018. The analytical method included 36 target analytes, among them the ether-based replacements GenX, ADONA and F-53 B. On board, 1 L water samples were spiked with 400 pg internal standards and loaded onto preconditioned solid phase extraction cartridges. After a washing step, the cartridges were dried under vacuum and stored at -20 °C. Further analysis was performed back at Helmholtz-Zentrum Geesthacht. After elution of the target compounds, eluates were reduced to 150 µL and [$^{13}C_8$]-PFOA was added as injection standard. Instrumental analysis was performed by HPLC-MS/MS. Concentration and composition profiles of PFASs will be compared considering the distance to emission areas, ocean currents and circulation, different water layers and potential correlations to salinity and temperature. In combination, this will give information on transport and sources of PFASs from the North Sea to the Arctic. Regarding GenX and other emerging PFASs, the results may provide additional evidence for long-range transport potential. This can be valuable to evaluate these compounds regarding future regulations.

538

Spatial trends and tissue distribution of per- and polyfluoroalkyl substances, extractable organic fluorine and total fluorine in marine mammals

K. Spaan, C. Van Noordenburg, L. Schultes, Stockholm University / Department of Environmental Science and Analytical Chemistry; A. Roos, Swedish Museum of Natural History / Department of Environmental Research and Monitoring; S.D. Shaw, M.L. Berger, Shaw Institute; M. Heide-Jørgensen, K. Laidre, Greenland Institute of Natural Resources / Climate Research Center; S.M. Granquist, Marine and Freshwater Research Institute; M.M. Plassmann, Stockholm University / Department of Environmental Science and Analytical Chemistry; J.P. Benskin, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

Per- and polyfluoroalkyl substances (PFASs) are a diverse class of anthropogenic substances which display extreme persistence. Long-chain perfluoroalkyl acids are a particularly insidious class of PFAS due to their tendency to bioaccumulate and links to adverse effects in organisms. Despite numerous phase outs and international regulations, manufacture of alternative substances with similar physico-chemical properties continues. A recent report by the OECD listed more than 4700 PFASs-related CAS numbers, but the actual number of PFASs in global circulation may be higher. The objectives of this study were to address the structural diversity and vast number of PFASs accumulating in marine top predators using a multi-platform approach combining targeted PFASs analysis with suspect screening on HPLC-Orbitrap-MS and analysis of extractable organic fluorine (EOF) and total fluorine (TF) using combustion ion chromatography (CIC) to estimate the fraction of unidentified fluorinated substances. Liver samples from eleven different marine mammal species (polar bears, porpoises, dolphins, whales and seals) were collected from four locations (Sweden, Iceland, Greenland and USA Atlantic) to evaluate spatial trends. Additionally, nine different tissue samples (liver, lung, kidney, blood, serum, blubber, muscle, skin and ovary) of a killer whale were obtained to study the distribution of PFASs in a top predator. A total of 22 PFASs were detected over all species, with PFOS as dominant contaminant in most samples in concentrations of up to 1600 ng/g. PFUnDA was the dominant compound in humpback whale (Greenland), whereas the precursor 3-perfluoroheptyl propanoic acid (7:3 FTCA) dominated in harbor porpoise, harbour seal (US Atlantic) and grey seal (Iceland). Harbor porpoises from US and Sweden had comparably high Σ_{36}PFASs concentrations, while West Greenland porpoises had lower concentrations. In the killer whale, liver tissues contained the highest Σ_{36}PFASs concentrations (434 ng/g), accounting for 39% of all other tissues. Blood, lung, serum, kidney and ovaries had Σ_{36}PFASs concentrations of 100 up to 150 ng/g, while muscle, blubber and skin had comparably low Σ_{36}PFASs concentrations ranging from 12 to 32 ng/g. Overall, these data give an overview of the occurrence of legacy, emerging and unknown PFASs in marine mammals from the northern hemisphere including their spatial and tissue distribution.

539

Toward a Comprehensive Emission Inventory of C4 to C10 Perfluoroalkanesulfonic Acids and Related Precursors: Focus on the Life Cycle of C6- and C10-Based Products

M. Scheringer, ETH Zurich / Institute of Biogeochemistry and Pollutant Dynamics; J. Boucher, ETH Zurich; I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry; K. Hungerbühler, ETH Zurich; Z. Wang, ETH Zurich / Institute of Environmental Engineering

Perfluoroalkanesulfonic acids (PFSAs) are an important class of per- and polyfluoroalkyl substances (PFASs). Of all PFSAs, perfluorooctanesulfonate (PFOS) and its precursors have been used most extensively. However, the C_6 and C_{10} homologues of PFOS, perfluorohexane- and perfluorodecanesulfonate (PFHxS and PFDS), were also used in many applications, often as surfactants or for surface protection. However, compared to PFOS, much less is known about their production volumes and uses. They have properties similar to those of PFOS and have also been released to the environment as shown by field measurements. Here we build on earlier work on compiling a global emission inventory for PFOS and use a similar approach to estimate global emissions of PFHxS and PFDS. The emission inventories for PFHxS and PFDS were calculated by integrating data about the production, use, and disposal of relevant chemicals collected and extrapolated from publicly available information with emission factors of different life-cycle stages. Included were PFHxS and PFDS, the sulfonyl fluorides PHxSF and PDSF, and the perfluorohexane and -decane sulfonamides and sulfonamidoethanols (*x*FHxSA/Es and *x*FDSA/Es). In a second step, the inventories were fed into a global environmental fate model, CliMoChem, to calculate environmental concentrations, which were then compared to measurements in seawater. A majority of the emissions are estimated to have occurred from production in the US, Western Europe and Japan before 3M's phase-out of POSF-based products in 2002 (113–864 t for PFHxS; 38–370 to for PFDS). Emissions of PFHxS are predicted to continue from product use and disposal (1–21 t) and degradation of *x*FHxSA/Es (1−66 t) between 2016 and 2030. The ranges of modeled concentrations include most of the field measuments. The modeled concentrations rise most rapidly in the northern temperate zone of the model, where most production occurred, and they reach a peak around 2002. More northern and southern zones show a delay before concentrations begin to rise after the start of production and also peak concentrations occur later. Elevated environmental concentrations of PHxSF, PDSF, and their derivatives are predicted to continue for decades to come, and zones farther from the source regions have not yet even reached their estimated peak concentrations. The favorable comparison with field concentrations indicates that our emission inventories are plausible, despite all uncertainties involved.

540

Short-Chain Fluorotelomer-based PFAS: Recent Advances in Toxicology, Biodegradation, Water Remediation and Alternatives Assessment

S. Korzeniowski, BeachEdge Consulting; k. cockshott, AGC Chemicals Europe / Compliance; J. Baptista, Fluoro Council

Per- and polyfluoroalkyl substances (PFAS) is a term that describes a wide and diverse array of chemistry containing fluorine and carbon. It is noteworthy that the chemistry and properties are vastly different across the various PFAS categories and classes. The primary focus of this presentation will be on the fluorotelomer-based products with six or less fluorinated carbons ("short chain") including fluorosurfactants, side-chain fluoropolymers and the potential metabolites and degradation products such as perfluorohexanoic acid (PFHxA). Fluorotelomer-based products can be in either the polymeric or non-polymeric PFAS categories. Within the non-polymeric PFAS category, fluorotelomer-based surface active agents (e.g. "fluorosurfactants") are used in complex multi-component formulations such as cleaning products, paints, coatings and Aqueous Film Forming Foams (AFFF). The non-polymeric fluorotelomer-based products provide superior surface wetting and leveling properties and unmatched AFFF fire-fighting performance on high-hazard Class B (i.e., hydrocarbon & polar solvent liquids) fires. Within the polymeric PFAS category are the side-chain fluorotelomer-based repellent products that are used in carpets, paper products and textiles providing essential and critical properties on high-end performance and medical garments, work wear, first responder gear and in military uses. The remarkable strength of the C-F bond provides products with superior resistance to extreme thermal, chemical and environmental conditions. This bond strength also makes them resistant to degradation and persistent in the environment. Industry best practices on handling and use will be reviewed. There have been significant advances in short-chain toxicology studies (development/reproduction; endocrine disruption), human health assessments, aerobic and anaerobic soil bio-degradation studies, progress in the removal of short-chain acids from ground and drinking water, and various other assessments. This presentation will summarize a number of these critical and significant advances and present the results in the context of the overall risk in using the short-chain fluorotelomer-based products. In addition, we will discuss decision criteria to help in the assessment of alternatives (risk vs. exposure), as well as challenges and success in the development of short-chain fluorotelomer-based products and an overview of their value-in-use including some critical end uses.

Contaminated Sediments: an Understudied Environmental Compartment (I)

541
Automated SPME with reduced equilibration time for measuring freely dissolved concentration of hydrophobic organic chemicals in solid matrices
C. Vitale, University of Insubria; K. Knudsmark Sjøholm, Technical University of Denmark (DTU) / DTU Environment; A. Di Guardo, University of Insubria / Department of Science and High Technology; P. Mayer, Technical University of Denmark / Department of Environmental Engineering
Hydrophobic organic chemicals (HOCs) exhibit very strong sorption to the soil/sediment organic matter, and their water-organic carbon distribution coefficients (K_{OC}) are generally larger than 10^4-10^5 L/Kg. Freely dissolved concentration (C_{free}) of HOCs is then a more relevant measure than total concentration. C_{free} is a well-defined parameter for expressing chemical exposure and (bio)availability, since C_{free} quantifies the effective concentration for diffusion and partitioning, and to a large extend also for bioconcentration processes and toxicity. Although equilibrium sampling (e.g. by using Solid Phase Microextraction, (SPME)) is a powerful tool for determining C_{free} of HOCs, it generally requires too long equilibration times in the range of few days up to weeks or even months, virtually impossible to conjugate with time and cost-efficient methods and automated devices. Novel approaches to speedup sampling kinetics of HOCs are therefore needed. In the present study, two fully automated SPME methods for determining C_{free} of HOCs in sediment and soil samples were developed: 1) direct immersion (DI)-SPME at 35 °C and 2) headspace (HS)-SPME at 80 °C. The HS-SPME method was tested and cross-validated against the DI-SPME method to shorten equilibration time further. The assumption was that the matrix to SPME coating partition coefficients are temperature independent, which implies that the equilibrium concentrations in the fiber are the same for HS-SPME and DI-SPME. Passive dosing from preloaded silicone rods was used as calibration method. The two approaches yielded similar results thereby cross-validating each other. Sampling kinetics with HS-SPME at 80 °C were much faster compared to DI-SPME at 35 °C with equilibration times generally within 2-3 hours. Finally, PCB total concentrations (C_{total}) (including C_{free} and PCB associated to the solid matrix) were measured based on spiked 13C labelled PCB standards and K_{OC} values were determined as ratio of C_{total} over C_{free},normalized to the sample specific fraction of organic carbon. Data presented here showed that HS-SPME at elevated temperature is a new, practical and valid alternative to other passive sampling methods for determination of C_{free} of HOCs in solid matrices.

542
Effects of simulated resuspension and amendment with activated carbon on metal and organic pollutant release from contaminated sediments
R.A. Rämö, Stockholm University / Dept of Ecology, Environment and Plant Sciences (D; S. Bonaglia, Stockholm University / Dept of Ecology, Environment and Plant Sciences DEEP; I.E. Nybom, Stockholm University; A. Kreutzer, HAW Hamburg; G. Witt, HAW Hamburg / Department of Environmental Engineering; A. Sobek, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; J. Gunnarsson, Stockholm University / Department of Ecology, Envionment and Plant Sciences (DEEP)
Contaminated coastal sediments are a growing concern for ecosystem and human health. The harbor of Oskarshamn in south-east Sweden is heavily contaminated with As, Cu, Cd, Hg, Pb, Zn and the hydrophobic organic contaminants (HOCs) PAHs, PCBs, and dioxins. A remediation project has recently removed 400 000 m^3 of contaminated sediments from the inner harbour, however, the outer harbour is highly contaminated and would be logistically difficult to dredge. This study is part of the research project CAPTIVE (capping with reactive sorbents), where we evaluate the efficiency and applicability of remediation using reactive srobents *in situ* in the outer harbor of Oskarshamn. Amendment with activated carbon (AC) has been shown to effectively bind and reduce the bioavailability of HOCs in sediment. We present results from a laboratory experiment, where contaminant release from intact sediment cores of the outer harbour was studied with and without addition of a thin layer cap of either powdered (PAC; 15-35 μm) or granular AC (GAC; 425-850 μm) mixed together with clay. The AC dose (0.6 kg m^{-2}) was in the low range compared to other studies on thin layer capping with AC. We also tested the effects of particle resuspension on contaminant release by simulating resuspension using mechanical stirring. Results indicate that PAC amendment significantly reduced the release of PCBs and PAHs to overlying water. GAC amendment had no effect on PCB and PAH retention in static condition (no resuspension), but reduced the release of PCBs and PAHs in resuspended conditions. Resuspension led to an increased release of PCBs and PAHs from sediment. For metal cations, thin-layer capping with AC reduced the release of Cd, Co, Cu, U and Zn cations from sediments. No significant effect of AC capping was observed for Fe, Mn, Ni, and Pb. Resuspension generally decreased the release of Cd, Co, Mn and Zn, whereas Cu, Fe, Ni, Pb and U were not affected by resuspension. However, resuspension may cause increased transport of particle-bound contaminants from the harbour. The results motivate further research to find a suitable reactive cap material that may withstand resuspension and maintain a high retention efficiency over time without adverse effects on benthic organisms. *Pending results on sediment and pore water concentrations of HOCs*.

543
Sorption of polycyclic aromatic hydrocarbons (PAHs) to biodegradable and conventional plastic materials in contaminated sediments
P. Näkki, Finnish Environment Institute SYKE; E. Eronen-Rasimus, H. Kaartokallio, Finnish Environment Institute SYKE / Marine Research Centre; H. Kankaanpää, Finnish Environment Institute / Marine Research Centre; E. Vahtera, City of Helsinki / Urban Environment Division; O. Setälä, Finnish Environment Institute / Marine Research Centre; M. Lehtiniemi, Finnish Environment Institute, Marine Research Centre / Marine Research Centre
Plastic debris is a growing threat in marine environments. The high abundancies of different-sized plastics on seafloors worldwide have led to suggest that these habitats could act as sinks for marine plastic debris. Being very resistant to degradation, plastics can cause long-term harm on seafloors for example by smothering and entangling organisms, or inhibiting gas exchange in the sediment-water interphase. It has also been observed that plastics can leach out harmful substances and adsorb environmental contaminants, such as polyaromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs) from their surroundings; when ingested, plastic with their co-contaminants can pose threat to biota and food webs. To combat harm caused by persistent conventional plastics, biodegradable plastic materials have been proposed as a solution. However, there is currently very little knowledge on the degradation of biodegradable plastics in marine environments, and their ultimate fate and effects compared to their predecessors. Hence, a long-term laboratory experiment was conducted to study the sorption of PAHs from sediments and seawater to four types of conventional and biodegradable plastics; polystyrene (PS), polyamide (PA), cellulose acetate (CA) and poly-L-lactic acid (PLLA), and to study the microbial communities on these materials. Each plastic type was cut into different-shaped pieces with surface area of 1 cm^2 and 20 pieces of each plastic type were incubated in field-collected sediments or seawater for 14 weeks. Sediment and near-bottom water for the experiment were collected from two sites on the coast of Helsinki: West harbor, which was Europe's second most active passenger harbor in 2016, and Vanhankaupunginlahti, which is an enclosed bay that has been the recipient for municipal waste waters until the 1980's. Concentrations of selected PAHs were measured from the sediments before the experiment and from the plastics after the incubation period. The preliminary results indicate that there are differences in the sorption capacities of plastic types and measured contaminants in both of the studied matrices (sediment and seawater). These results emphasize the need to further study the properties and fate of biodegradable plastic materials in the marine environment to be better able to assess their potential risks to ecosystems.

Depth-related analysis of sediment and pore water in microcosms
A. Dorn, RWTH Aachen University / Institute of Environmental Research; P. Dalkmann, Bayer AG Crop Science Division / Environmental Safety; D. Faber, Bayer AG, Crop Science Division / BAG-RD-CS-EnSA-Ecotoxicology; K. Hammel, E. Hellpointner, Bayer AG, Crop Science Division / Environmental Safety; E. Bruns, Bayer AG, Division Bayer CropScience / Ecotoxicology; H.

Hollert, RWTH Aachen University / Institute for Environmental Research
Sediment toxicity testing of plant protection products (PPP) is gaining an increasing awareness within the scientific and regulatory community. Currently, PPP concentrations in sediment and pore-water of Chironomid toxicity studies acc. to OECD test guideline (TG) 218/219 are determined as mean over the entire sediment layer of the test system. Hence, a depth-related analysis can contribute to a more accurate assessment of the effective exposure for the predominantly surface sediment dwelling organism in these test designs. Therefore, a methodology was used enabling the depth-related analysis of test compounds in pore-water and adsorbed to sediment. After removing the water phase, plastic tubes were stung into the ca. 15 mm-thick sediment phase, which was subsequently frozen by liquid nitrogen. By the use of a cutting device, the sediment cores were cut into three slices providing a thickness of ca. 5 mm. Each sediment slice was centrifuged to isolate the pore-water. A sequential extraction was performed to determine the sediment adsorbed residues. After combining the sediment extracts, pore-waters and extracts were analysed by LC- MS/MS. Chironomid toxicity studies were and will be conducted acc. to OECD TG 218 and 219 applying four model compounds B (Koc≈ 300 L/kg), C (K_{oc}≈ 0 L/kg), D (K_{oc}≈ 3900 L/kg) and E (K_{oc}≈ 3400 L/kg) separately to the test systems. To investigate the spatio-temporal distribution of the compounds, test systems are incubated and processed at different days after treatment (DAT). After application to the water phase of the test systems (OECD TG 219), C was predominantly found in the overlying water phase and pore-waters of all sediment layers at 1-DAT. The amount of C measured in the top layer remained highest until 14-DAT. After 14-DAT, C concentrations levelled out until 28-DAT over all three layers due to low diffusion hindrance of this low adsorbing compound. Consistently, the mobility of C was proven after application to the sediment phase (OECD TG 218). One DAT, significant differences of the amounts of C could be measured in the pore-waters of the three-layer depths. From 3-DAT until the study end, the compound concentration gradient between the layers had balanced. These first results indicate that the used methodology can provide a substantial contribution to a more realistic determination of exposure concentrations in chronic water-sediment toxicity tests, opening the discussion for an improved sediment risk assessment.

545
The bioavailability to fish of oil entrained in porous river bed sediments
J. Adams, R. Brown, P.V. Hodson, Queens University / School of Environmental Studies
The expanding shipment of oil via pipeline and rail in Canada has increased the risk of spills to freshwater ecosystems. However, the fate of oil in freshwater is not well understood, particularly in west coast rivers where salmonids reproduce. These rivers are shallow and turbulent, with a high gradient, variable flow rates, and porous bed sediments derived from glacial till. In-stream pressure gradients create hyporheic flows through bed sediments between zones of down-welling and up-welling. Salmonids spawn in these zones because continuous flows of fresh water promote egg development until hatch (6-7 months). Hydraulic modelling demonstrates that hyporheic flows could entrain oil droplets into bed sediments, and model sediment columns readily trap oil between sediment particles. Water passing through columns of oil-contaminated sediment contains measurable concentrations of hydrocarbons that decline over weeks as the oil weathers by water washing. We assessed the potential exposure of salmonid embryos to oil in interstitial waters by measuring the bioavailability of dissolved hydrocarbons to juvenile trout exposed to effluents from columns of oiled sediments. Columns were loaded with a gradient of droplets of light and medium crude oil, heavy fuel oil, and diluted bitumen products. The amount of oil retained by the columns and the concentrations in water flowing through the columns increased with loading. The bioavailability of oil to trout, as indicated by induction of liver cytochrome P-4501A enzymes, increased with oil loading by up to 50-fold that of trout in effluent from non-oiled columns. Induction declined with time but persisted for at least 4 weeks. These experiments suggest that oil droplet trapping in bed sediments may occur following oil spills to rivers and pose a prolonged risk to the survival and development of salmonid eggs.

546
Behavior and biochemical responses of the polychaete Hediste diversicolor to polystyrene nanoplastics
M. Silva, A. Pires, Universidade de Aveiro / Biologia; M. Oliveira, RMS-TekebBio, LDA; D. López, P. Valente, Universidade de Aveiro / Biologia; E. Figueira, University of Aveiro / Biology CESAM
Several stressors have been identified as potential key and/or emerging drivers of environmental change that may significantly influence marine near-shore ecosystems. Among these stressors, small plastic particles have been increasingly reported in aquatic environments. Although an increasing number of studies have been focusing in the effects of microplastics, the information concerning the effects of nanoplastics to marine organisms can be considered scarce, despite the increased potential to be incorporated by organisms. In the marine environment, nanoparticles are expected to agglomerate/aggregate, eventually settling and becoming available for benthic organisms. Nonetheless, the information concerning their toxicity impacts to organisms like polychaetes is scarce. Polychaetes are often the most abundant group of organisms in benthic communities and as they are in intimate contact with sediments, they are maximally exposed to harmful materials present there. Polystyrene plastics are among the most produced worldwide, for products with low reuse, making this polymer commonly found in the aquatic environment. Thus, this study aimed to assess the effects of waterborne polystyrene nanoplastics (100 nm) on burrowing activity and biochemical endpoints associated with oxidative status, neurotransmission and energy metabolism in Hediste diversicolor. Specimens of H. diversicolor were collected in a reference site of Ria de Aveiro lagoon (Portugal) and after acclimatization, 21 organisms per experimental condition were randomly distributed per 3 glass aquaria and were exposed for 28 d to different concentrations of 100 nm polystyrene particles (0.0; 0.005; 0.05; 0.5; 50.0 mg/L). Overall, exposure to polystyrene nanoplastics resulted in an impared burrowing behaviour in exposed polychaetes. Moreover, nanoplastics affected assessed biochemical endpoints like cholinesterase activity (marker of neurotoxicity) and electron transport (associated with metabolic activity). These results explain the observed altered behaviour. Nonetheless, no peroxidative damage was found suggesting that alterations in antioxidant defences prevent damage. The results obtained in this study indicate that tested conditions induce behaviour and biochemical alterations in the studied polychaetes. Considering that nanoparticles are expected to settle in the sediments, this study shows that these organisms may be a target of potential pernicious effects of nanoplastics.

Bridging the Gap: Maximizing the Role of Mechanistic Approaches (Including Omics) for Better Chemical Safety Decisions Across Humans and Ecosystems (I)

547
High throughput metabolomics of single zebrafish embryos
A. Ribbenstedt, Stockholm University / Department of Environmental Sciences and Analytical Chemistry (ACES-O); M. Posselt, Stockholm University / Department of Environmental Science and Analytical Chemistry; C. Brunius, University of Gothenburg Sweden / Department of Biology and Biological Engineering; J.P. Benskin, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES
By substituting adult fish with embryos, the Fish Embryo Acute Toxicity (FET) test (OECD 236) has addressed some of the ethical and financial challenges associated with toxicity testing under REACH (Registration, Evaluation, Authorization and Restriction of Chemicals) legislation. Nevertheless, information obtained through the OECD 236 assay remains limited to conventional toxicological endpoints (e.g. LC_{50}, LOAEL, NOAEL), which provide little insight into a chemical's mode of action. With the ever increasing number of chemicals entering the European market, a mechanistic understanding of the adverse effects of these substances is clearly needed. This is highlighted by the introduction of the Adverse Outcome Pathway (AOP) program by the OECD in 2012. Metabolomics is among the Omic sciences which have shown considerable promise in generating data to support AOP development; however, pairing metabolomics assays with regulatory testing, and interpretation of metabolomic data within a regulatory context remains challenging. In this proof-of-principle study we present the application of metabolomics to single zebrafish embryos exposed to the beta-blocker propranolol according to the OECD 236 guideline. Incubation, microscopy, embryo extraction, and instrumental analysis were all performed in the same 96-well plate, resulting in a total assay time (i.e. testing of 6 doses of propranolol plus positive and negative controls, measurement of conventional endpoints as well as generation and multivariate analysis of metabolomics data from 96 samples) of < 12 days. Statistical analysis using a random forest repeated double cross-validation framework with unbiased variable selection (MUVR) revealed dose-specific perturbations of the metabolome, including at doses below the conventional lowest observed adverse effect level (LOAEL). By anchoring metabolomic effects observed at low dose to those at high dose (i.e. in the presence of an apical endpoint), results of this assay could potentially be interpreted within a regulatory context. Thus, in additional to rapidly generating both conventional and MOA-specific data suitable for regulatory applications, this assay could be more sensitive for detecting adverse effects at low doses.

548
Fish hepatic proteome as a tool for environmental management of the safety limits of cadmium
H. Silva de Assis, L. Fernandes, UFPR / Pharmacology
The aquatic environment constantly receives different contaminants, among them is the nonessential metal cadmium (Cd). This metal is largely used in industry, being present in products as batteries, pigments, and plastics. As other metals Cd can bioaccumulates in tissues of exposed organisms. In this study adult male of *Rhamdia quelen* were exposed to 0 (control), 1 and 10 $\mu g\ L^{-1}$ of Cd. After 15 days, animals were anesthetized in benzocaine and euthanized by medullar section, the liver was collected to proteomic analysis. Proteins were extracted in lysis buffer, run in SDS-PAGE, digested with trypsin and purified. Samples were submitted to liquid chromatography and quantified by mass spectrometry. Proteins were

identified by MaxQuant software using Siluriforms GenBank database. The results showed more than 1500 proteins expressed in liver of *R. quelen*. Among them, the histone 2B, an important protein in cell cycle, acting in the regulation of chromatin structure, was more expressed at 1 $\mu g\ L^{-1}$ of Cd. In the same group the β subunit of the protein Sec61, a protein translocation channel responsible to export the proteins throughout endoplasmic reticulum membrane, was less expressed. In the animals exposed to 10 $\mu g\ L^{-1}$ of Cd more proteins were differentially expressed. In this group, the myosin 9 increased and the myosin regulatory light chain 12B and myosin light polypeptide 6 decreased, both proteins involved with cytoskeletal activity. The expression of calmodulin, a calcium (Ca^{2+})-binding protein, therefore acting as mediator for the action of different Ca^{2+} dependent proteins and cellular processes, decreased at the higher Cd concentration. Some studies observed that Cd toxicity is related to Ca^{2+} homeostasis and the decrease in calmodulin is another evidence of this mechanism. Regarding to the endocrine system, the expression of the membrane-associated progesterone receptor component 2 decreased in fish exposed to 10 $\mu g\ L^{-1}$ of Cd. This receptor promotes a fast progesterone response, allowing a rapid modulation of the cell action in response to the activation of genomic signaling pathway. Although the concentrations tested are allowed in the Brazilian environmental legislation they altered the expression of important proteins. Thus, proteomics can be a tool to better understand the Cd mechanism of action and to improve the environmental management of health-supporting ecosystems such as freshwater resources and human safety limits in the legislation.

A multi-omics approach for identifying and validating molecular key events using the Adverse Outcome Pathway framework

S.E. Whitlock, School of Biosciences, University of Birmingham / Environment; N. Taylor, Cambridge Environmental Assessments (CEA) / Ecotoxicology; S. Schade, Birmingham University / Biosciences; E. Butler, Unilever RD Colworth / Safety and Environmental Assurance Centre SEAC; B. Campos, Unilever R&D / Safety and Environmental Assurance Centre SEAC; S. Gutsell, Unilever / SEAC; J. Zhou, University of Birmingham / Computer Science; N. Shi, S. He, University of Birmingham / School of Computer Science; J. Colbourne, M.R. Viant, University of Birmingham / School of Biosciences; G. Hodges, Unilever Research / Safety and Environmental Assurance Centre

The Adverse Outcome Pathway (AOP) framework is a concept developed in recent years to improve the risk assessment of chemicals. AOPs aim to compile existing knowledge about responses to toxicants at successive levels of biological organisation to improve predictions of adverse outcomes. Key events (KEs) within AOPs can be seen as deviations from a healthy state via a stress response that may be predictive of an AO and thus an indication of the potential health hazards of a chemical. We designed a three-phase experimental strategy, using transcriptomics, metabolomics and targeted assays to identify and validate molecular KEs associated with an AO relevant to chlorobenzene: non-polar narcosis. During phase 1 of the study, *Daphnia magna* were exposed to chlorobenzene at 0.032 and 0.1 mg/L at high temporal resolution (11 timepoints between 0 and 8 days, continuing to 21 days for phenotypic endpoint measures), to identify key timepoints at which significant molecular perturbations, potentially indicative of a chronic AO, could be observed. Based on this, we found that the highest number of significantly changing metabolites/lipids and differentially expressed genes between the control and chlorobenzene treatment groups occurred at 4 and 8 hours and at 6 and 7 days. During phase 2, we tested the reliability of our phase 1 observations at these four key timepoints. Using a new machine learning pipeline, putative KEs were mined from the ‘omics data. Candidate biomarkers, representative of putative KEs, were selected from subgroups of highly correlated genes and metabolites using sparse canonical correlation analysis. So far, this approach has identified 60 candidate genes thought to be involved in KEs relating to chlorobenzene exposure. In phase 3 (currently underway), the dose-response characteristics of the putative molecular KEs are being investigated to validate our discovered KEs, and to probe key event relationships (KERs). Overall our work demonstrates the potential of ‘omics technologies for filling knowledge gaps and for improving our understanding of chemical Mode or Mechanism of Action (MoA or MechoA), which will in turn allow more comprehensive risk assessments to be conducted.

Cross omics effect assessment of co-exposure to plasticisers and metals on neurodevelopment

D.A. Sarigiannis, N. Papaioannou, A. Gabriel, Aristotle University of Thessaloniki / Chemical Engineering; O. Anesti, Aristotle University of Thessaloniki / HERACLES Research Center on the Exposome and Health, Center for Interdisciplinary Research and Innovation; S. Karakitsios, Aristotle University of Thessaloniki / Chemical Engineering

This study was part of the largest project on the exposome globally, HEALS, which proposes the functional integration of cross–omics data to derive exposome-wide causal associations with adverse health outcomes. Untargeted metabolomics of 600 urine and plasma samples from cohorts running in Poland, Slovenia, Croatia, Greece and Italy, which studied the environmental causation of neurodevelopmental disorders in neonates and children across Europe. The aim of this study was to obtain mechanistic insight into how co-exposure to phthalates and heavy metals causes neurodevelopmental dysregulation coupling human data with in vitro assays. Specifically, HepaRG cells were exposed to mixtures of DEHP, DiNP, and BBzP phthalates, methylmercury and total mercury. These were the most abundant pollutants in the human cohorts. The effective in vitro concentrations of the chemicals were estimated through estimation from human biomonitoring data using internal dosimetry modeling on the INTEGRA computational platform. High dimension pathway analysis of transcriptomics and proteomics data revealed that co- exposure to phthalates and metals leads to dysregulation of the urea cycle due to alterations in the expression levels of arginase-1 and -2, argininosuccinate synthase, carbamoyl-phosphate synthase, ornithine carbamoyltransferase, and argininosuccinate lyase. Co-mapping proteomics and metabolomics data showed that their common drivers are responsible for the allostasis of metabolic pathways related to choline, phosphatidylcholine, phospholipases and triacylglycerol metabolism. The identification of the urea, phosphatidylcholine biosynthesis I and phospholipases metabolic pathways is of particular interest since these pathways have been also identified in human samples from the studied cohorts using untargeted metabolomics analysis as being associated with impaired psychomotor development in children at the age of three to six. Our work reveals that co-exposure to plasticizers and metals disturbs biochemical processes related to mitochondrial respiration during critical developmental stages that are clinically linked to neurodevelopmental perturbations.

551

Systems biology approach reveals the effects of exposure to urban environment

J. Kronberg, U. Võsa, Institute of Genomics, University of Tartu / Estonian Genome Center; A. Kalnapenkis, Institute of Genomics, University of Tartu; A. Metspalu, T. Esko, Institute of Genomics, University of Tartu / Estonian Genome Center

Introduction. Vast amounts of data have been and are generated for understanding various environmental stresses, ranging from most controlled laboratory exposures to field studies. It is also important to understand the exposure effects to humans, but for ethical reasons, these must be studied differently. Human exposomics studies have previously used personal devices, occupational and living area information for the study participants. Aim. Our aim was to explore the use omics data from a population-based biobank to understand the effects of exposure to urban life. Estonian Biobank currently has 52000 people genotyped and other omics data is available for some individuals. For example, 10840 individuals have ^{1}H-NMR metabolomics, 917 Illumina BeadChip gene expression data and 442 Olink proteomics data available. In addition, for each individual, questionnaire data and data from electronic health records are also available. Results. Our results show that there are 717 genes differentially expressed between city-born and rural-born people and 2319 genes differentially expressed between town-born and rural-born people. The main differences are between people born in urban areas as compared to rural areas. Specifically, genes differentially expressed between urban and rural areas are enriched in Gene Ontology terms such as “metabolic process”, “gene expression”, “organic cyclic compound binding” and “regulation of response to stress”. To further understand the large set of differentially expressed genes, we created a mutual information network. This network was modularized and functionally annotated, revealing modules enriched in various biological functions and diseases. For example, one module which is enriched in Gene Ontology term “response to stimulus”, is also enriched in brain disease and nervous system diseases. Other significant Gene Ontology terms include “Response to stress”, “translation”, “gene expression”, “DNA damage response, signal transduction by p53 class mediator”. Enriched diseases include immune system diseases, neoplasms, metabolic diseases and liver diseases. Conclusion. Our results have shown that systems biology analysis of omics data from a population-based biobank analysed with systems biology methods provide meaningful results to be explored further.

552

Environmental contaminants modulate the transcriptional activity of polar bear (Ursus maritimus) and human peroxisome proliferator-activated receptor alpha (PPARA)

H. Routti, Norwegian Polar Institute; M. Berg, University of Bergen; R. Lille-Langøy, L. Øygarden, University of Bergen / Department of Biological Sciences; M. Harju, NILU Norwegian Institute for Air Research; C. Sonne, Aarhus University AU Arctic Research Centre / Department of Bioscience; R. Dietz, Aarhus University / Department of Biosciences, Arctic Research Centre; A. Goksøyr, University of Bergen / Department of Biology

Species at the top of Arctic marine food webs, such as the polar bear (*Ursus maritimus*), accumulate high levels of organohalogen contaminants (OHCs) including polychlorinated biphenyls (PCBs), organochlorine pesticides, and perfluoroalkyl substances (PFASs). Recent correlative field and *in vitro* studies indicate that contaminants also target polar bear lipid metabolism. Contaminant-mediated adverse effects towards energy metabolism is of particular concern in polar bears due to global climate change. Exposure to environmental contaminants and their potential effects towards energy metabolism is also of high concern in human populations. Exposure to PFASs and other environmental contaminants has been linked to metabolic disorders in animal models and human epidemiological studies. Peroxisome proliferator-activated receptor alfa (PPARA/NR1C1) is a ligand activated nuclear receptor that is a key regulator of lipid metabolism in tissues with high fatty acid catabolism such as the liver. However, PPARA-ligand interactions are likely species-specific, because sequences of ligand binding domains (LBD) of nuclear receptors vary between taxa. Understanding species-specific receptor-ligand interactions is particularly important for risk assessment. Here, we cloned PPARA from polar bear liver tissue and studied *in vitro* transactivation of polar bear and human PPARA by environmental contaminants using a luciferase reporter assay. Six hinge and ligand-binding domain amino acids have been substituted in polar bear PPARA compared to human PPARA. Perfluorocarboxylic acids (PFCA) and perfluorosulfonic acids induced the transcriptional activity of both human and polar bear PPARA. The most abundant PFCA in polar bear tissue, perfluorononanoate, increased polar bear PPARA-mediated luciferase activity to a level comparable to that of the potent PPARA agonist WY-14643 (~8-fold, 25 μM). Several brominated flame retardants were weak agonists of human and polar bear PPARA. While single exposures to polychlorinated biphenyls did not, or only slightly, increase the transcriptional activity of PPARA, a technical mixture of PCBs (Arochlor 1254) strongly induced the transcriptional activity of human (~8-fold) and polar bear PPARA (~22-fold). Polar bear PPARA was both quantitatively and qualitatively more susceptible than human PPARA to transactivation by less lipophilic compounds.

New Frontiers in Life Cycle Inventory Data Collection and Modelling (I)

Combining Computable General Equilibrium Model and Life Cycle Assessment for Carbon Footprint Projections in Japan
Y. Ichisugi, Tokyo City University; T. Masui, National Institute for Environmental Studies; N. Itsubo, Tokyo City University
Since 2015, Science Based Targets (SBT) have been paid attention in the world. The targets adopted by companies reducing GHG emission to keep global temperature below 2 degrees increase from that of preindustrial revolution. Approximately 440 companies in the world declared to follow the targets. The targets for the mitigation are based on the calculated results of Integrated Assessment Models (IAM) such as Asia-Pacific Integrated Model (AIM). However, these models usually do not consider the entire supply chain, because of the differences of the aims of application. In contrast, Life Cycle Assessment (LCA) considers the entire supply chain. On the other hand, most of the LCA studies use the current environmental data and normally do not include the dynamism of system (i.e. they are not temporally differentiated). Therefore, this study aims at the development of a dynamic evaluation of environmental burdenbased on life cycle thinking to use both advantages of IAM and LCA. We tried to develop the database using AIM/CGE [Japan] developed by the National Institute for Environmental Studies (NIES). In this study, we collect the fundamental data using LCA databases and estimate GHG emissions in the future considering the supply chain among industrial sectors. We estimated the GHG emissions in 2005 as a tentative result. The total emission is approximately 1.60Gt-CO2eq. We confirmed the validity compared with the existing report published by the Japanese ministry of environment. We estimated the environmental impact projection in the future considering scenario like Shared Socioeconomic Pathways (SSP).

554
Direct sampling to improve accuracy of Monte Carlo uncertainty analysis
C. Mutel, ETH Zurich / Laboratory for Energy Systems Analysis; P. Lesage, CIRAIG - École Polytechnique de Montréal / CIRAIG
Standard Monte Carlo sampling in LCA uses independent sampling of parameter values. Independent sampling is computationally simple, but neglecting correlation between inventory parameters leads to confusing or even impossible results. We present a new, simple, and powerful approach that allows for the inclusion of parameter correlations and avoids fitting errors through the standardized provision of pre-calculated sample values for certain parameters. We have implemented this approach in an open-source library called Presamples, which builds on top of the Brightway open-source LCA software framework.\n\nMost LCA software and databases allow for the use of parameterized datasets – datasets where certain parameter values are defined by variables and formulas. Similarly, such data can be generated by external process models. Our approach allows for parameterized sample values to be generated beforehand and used during sensitivity analysis. These values can be generated by authoritative sources and tested for validity and randomness.\n\nGlobal sensitivity analysis often requires specific sampling strategies, which are difficult to implement with conventional LCA software. By moving the generation and filtering of Monte Carlo samples outside the Monte Carlo iterative calculation, pre-calculated samples allow for the easier generation, validation, and exchange of such values.\n\nThere is a high degree of both spatial autocorrelation and correlation due to model uncertainty in regionalized CFs. Accurate representations of such uncertainty require CFs to be supplied directly by the LCIA model and used directly.\n\nIndependent sampling breaks mass, energetic, or other balances, as inputs are not linked to outputs. Similarly, market datasets should sum to a fixed value, usually one - a constraint that is broken by independent sampling. Pre-calculated samples allow such balances to be explicitly included, and allow for the use of measured data in market shares.\n\nWe illustrate our approach using case studies of parameterized datasets in ecoinvent, European electricity generation and trade, and regionalized land use.\n\nThe use of pre-calculated sample values presents significant potential to improve the realism of LCA uncertainty analysis results in many application scenarios. Our open-source software and standardized data format could form the foundation for the adoption of such pre-calculated samples throughout the LCA community.

Dynamic LCA modelling for metals production
S. Horn, A. Remes, T. Kotiranta, Outotec
Life cycle assessment (LCA) is widely used in environmental assessment, but its application in the mining and mineral sector is still in progress. The value chain of metals production combines vast amounts of information from disciplines such as geology, mining, metallurgy, technology, environment and economics, all having a link to the environmental impacts of the mine project. Furthermore, the data from these processes is spatially and temporally restricted. Advances in computing power and simulation software enable various data sets to be incorporated in a single digital platform enabling more efficient and transparent data sharing. In addition, linked data sets and simulation can support assessment and optimization of the project as a whole rather than focusing on optimization of individual events. The current study proposes an advanced option of collecting process data and adding dynamic capabilities to a continuous LCA-based process optimisation. It combines metallurgical process simulation with a standard life cycle approach (cradle-to-gate assessment) and allows the usage of real-time monitoring data (e.g. daily sequence) as primary data from the process. It also considers that the metallurgical balance is consistently correct over time. Moreover, it allows a prediction of the KPIs by using process simulation. The results from estimating the environmental impacts based on a dynamic, one-month data set of the underlying metals production process clearly indicates volatility in all the monitored KPIs and shows the impact of changing ore grades and plant capacities on the carbon emissions of the process. In this case, the total emissions will increase when the feed rate decreases, despite of an environmentally favorable effect of the increased recovery of the concentrator process. This is because the subsequent hydrometallurgical processing plant is most environmentally efficient with the highest possible production rate. In sum, instead of taking metal production as a black-box and its environmental impacts as a constant, LCA practitioners should keep in mind that that kind of non-dynamic approach is not able to adequately address site-specific impacts to capture the spatial and temporal dimension of the results. This dynamic model consisting of an advanced process simulation model linked to LCA will be able to produce reliable LCI data as well as predict and optimise the environmental impacts based on changing process conditions and ore types.

A bottom-up approach to build life cycle assessment models using agent-based models: the case of hydrogen supply chain for mobility
P. Baustert, Luxembourg Institute of Science and Technology LIST / Environmental Research and Innovation (ERIN); T. NAVARRETE GUTIERREZ, Luxembourg Institute of Science and Technology / Environmental Research and Innovation (ERIN); P. Meallet, Luxembourg Institute of Science and Technology / Environmental Research and Innovation; T. Gibon, Luxembourg Institute of Science and Technology (LIST) / Environmental Research and Innovation
Hydrogen has recently sparked a new research interest in hydrogen based mobility because of its potential as a means to store surplus energy from renewable sources for example. Hydrogen based mobility is currently only applied marginally in local or regional contexts, thus rendering the evaluation of environmental impacts of the hydrogen supply chains a challenging task. To investigate the claims regarding the environmental impacts of hydrogen from renewable energy sources we propose an agent-based modelling (ABM) framework to model the supply chain, feeding data to the inventory of a life cycle assessment (LCA) study. As an initial prototype of the framework, we have applied it to the greater region of Luxembourg. The objective of the study is to model how to satisfy the demand for hydrogen by the mobility sector, while minimizing the total hydrogen supply cost. The novelty of the approach does not rely on the use of ABM solely, but on the use of *emerging supply chains* from the ABM. With these supply chains as output of the ABM, the life cycle inventory (LCI) processes describing hydrogen production, storage and transport are connected among each other. The entire supply chain in turn is connected to the existing LCA process database. Finally the environmental impacts per functional unit (i.e., 1 kg of hydrogen at the pump) can be assessed. Preliminary results indicate that hydrogen from these emerging supply chains has a lower global warming potential compared to hydrogen from the existing market. During the presentation, the specific ABM implementation

details (Agent characterization, behaviours and environment), as well as simulation results will be used to illustrate how we derived the life cycle inventories and the actual life cycle assessment as well as the impact assessment.

Enhancing data creation and adaption to different user needs: approaches in managing a large LCI database
E. Moreno-Ruiz, G. Wernet, ecoinvent Association
LCI data are time-consuming to collect and process, and data gathering is often a major time factor for LCA practitioners. Innovative data handling and processing can save key resources for data gatherers, providers and users. The architecture of the ecoinvent database is becoming more adaptable, flexible and efficient for this purpose, at all levels of interaction. On the data entry side, ecoinvent has boosted the possibility of generating easy and high-quality data, by developing LCI creation support tools in different sectors such as waste and wastewater treatment, crop production, and petroleum refinery operation. Open to data providers, ecoinvent has fine-tuned its submission and review platform with the years, making it ready to manage even larger submissions more effectively. At the same time, ecoinvent also collaborates with databases that operate on ecoinvent' s background data but remain external. ecoinvent has been using a modular approach to generate different system models, based on the same peer-reviewed free-of-access unit processes, that represent multifunctional and independent inventories. Today, new features allow the creation of hybrid system models, where two distinct databases are linked together and can serve multiple purposes at the same time, to enhance the power of choice of the user. It is the case of the chemical database delivered for the EU Product Environmental Footprint (PEF), pilot phase, as well as for a hybrid database constructed to suit the needs on Swiss consumption modeling of the Swiss Federal Offices. We will describe these modulating features, that give even more flexibility to the calculation and use of the database and increase the usefulness that practitioners can draw from the same data.

The Indoor Environment: Emerging Contaminant Identification, Analysis and Quantification for Exposure Assessment

559
A coupled model of heat and chemical mass balance to consistently evaluate human exposure in indoor environments
A. Micolier, University of Bordeaux; F. Taillandier, University of Bordeaux / I2M GCE; G. Sonnemann, University of Bordeaux / The Life Cycle Group CyVi; O. Jolliet, University of Michigan / Department of Environmental Health Sciences, School of Public Health
New building design and renovation standards tend to increase airtightness and use of newer materials to meet current environmental challenges. This leads to particularly confined spaces in which a wide variety of chemicals are released from materials and surfaces and expose the occupants to multiple health hazards. Learning how to design energy efficient buildings with good indoor air quality is one of tomorrow's challenge. An important source of indoor air pollution arises from the chemicals embedded in the building materials that are released in the indoor air of the dwelling and whose physicochemical properties are thermally driven. Temperature in building materials is commonly considered as the same as the room temperature, affecting substantially chemicals diffusion and offgassing. Once released in indoor environments, their residence time is impacted by physical removals such as ventilation. However, the impact of most of the design choices on chemicals fate remains unclear. Therefore, there is an urgent need to address chemicals fate together with heat transfers. We propose a new approach to consistently evaluate the impact of early design choices on human exposure in indoor environments as well as on energy consumption by coupling heat and mass balance. A set of ordinary differential equations (ODE) is obtained to formulate the conservation laws of heat and mass in the gas and in the solid phase. Occupants exposure during building use stage is characterized by the Product intake Fraction (PiF) for each exposure pathway, used to comparison of the relative importance of these pathways, as well as the potential exposure between chemicals or building designs. Coupling heat and chemical mass transfers in the building envelope enables a better understanding of the chemicals fate in building materials. The model, implemented on a low-energy dwelling, demonstrates that an air renewal rate of 0.6 1/h with a heat exchanger was the best trade-off to reduce energy consumption while ensuring a satisfactory air quality and limiting exposure to off-gassed chemicals. This approach paves the way to guide early building design choices towards a better indoor air quality without burden shifting on the energy balance.

Indoor Dust/Air Partitioning: Evidence for Kinetic Delay for Low-Volatility SVOCs
T. Taskovic, Trent University / Department of Chemistry; J. Parnis, Trent University / Cemistry; D. Mackay, Trent University / Chemistry
Dust-air partitioning ratios were estimated using COSMO-RS solvation theory, using the "liquid oligomer" approach to represent dust as a solvation medium. Using a variety of oligomeric models based on typical constituents of household dust, $K_{Dust-Air}$ value (g^{-1}/m^{-3}) were estimated and. Oligomeric models based on the structure of polymeric nylon-66, lignin, cellulose, and two protein strands representing head and body hair keratin. Experimental data was obtained from three published sources: Venier et al., 2016 (BFRs in indoor air and settled dust; Tay et al., 2017 (flame retardants, PBDEs and hexabromocyclododecanes in house dust); , Luongo & Ostman, 2015 (organophosphate and phthalate ester in settled and airborne dust). The modelling results for the three data sets combined clearly show a lack of strong correlation between the estimated and experimental partition ratios ($R^2 = 0.65$). The deviation is greatest for relatively low vapor pressure molecular species. This observation suggests that the disparity is due to a "kinetic delay" associated with oleophilic substances, wherein chemicals with very low vapor pressures require relatively long times to reach equilibrium with surrounding air, resulting in measurements of log K(dust-air) higher than equilibrium values. The model improved steadily as the chemical species in question were eliminated in order of increasing vapor pressure, up to a cut-off of about VP = 10^{-5} Pa. With this change, *n*-octanol and cholesterol yielded the lowest RMSE and highest R^2, with n-octanol marginally outperforming cholesterol. The remaining models ranked according to diminishing hydrophobicity. The onset of kinetic delay at about 10^{-5} Pa indicates a value which could be considered to be a lower-limit for SVOC definition in indoor air contexts. A significant implication of this result is that indoor dust concentrations of such low vapour pressure SVOCs should not be used as an indirect measure of indoor air concentrations of these chemicals, since they will not be expected to be at equilibrium with the air. For such chemicals, calculated air concentrations will generally be consistently and often significantly higher than in reality, due to air turnover losses that occur much faster than the time to equilibration.

561
Do we need to re-think processes of chemical movement indoors?
M.L. Diamond, University of Toronto / Department of Earth Sciences; A. Anderson, University of Toronto / Department of Computer Science; C. Yang, University of Toronto / Department of Earth Sciences; L. Melymuk, Masaryk University, Faculty of Science, RECETOX / Research Centre for Toxic Compounds in the Environment (RECETOX); L. Jantunen, Environment and Climate Change Canada / Centre for Atmospheric Research Experiments & Department of Earth Sciences; S.A. Harris, Cancer Care Ontario & University of Toronto / Population Health and Prevention & Occupational Cancer Research Centre & Dalla Lana School of Public Health
Modern indoor environments contain numerous natural and synthetic chemicals held in consumer products, furnishings and building materials. People have typically not been considered in mass balance models of indoor chemical fate or in the case of the model of Zhang et al. (2014) treated as another compartment. In these models, chemical transport is described in terms of the physics of gas- and particle-phase compounds. Human activities can be important, such as cleaning, as a chemical removal process. However, consideration of those activities is limited. What if people's "everyday" activities directly influenced the transport of chemicals within the indoor environment? We conducted a study of 51 homes and their residents in Ontario, Canada. The study involved collecting information about the homes and residents, and chemical concentrations in air, floor dust, and wipes of surfaces of electronic devices and participants' hands. We analyzed 23 organophosphate esters (OPEs), 14 polybrominated diphenyl ether (PBDEs) congeners, 10 non-PBDE halogenated flame retardants (HFRs) and 6 phthalate esters. Detection frequencies were >80% for 5-8 OPEs, 3 PBDEs, 2 non-PBDE HFRs and all 6 phthalates. Almost all surfaces, namely electronic surfaces and hands (backs and palms), had similar chemical profiles contrary to the expectation of electronic surfaces being dominated by one or only a few flame retardants which was only the case for TVs. Thus, hand surfaces had indistinguishable chemical profiles relative to electronic surfaces, especially handheld electronic devices. The handheld devices had higher concentrations of all analytes than non-handheld devices, with the exception of DBDPE and BDE-209 that had elevated concentrations in TVs. We constructed chemical profile networks and analyzed their structure to investigate the relationship between chemical profiles on surfaces. Hands were central to the networks of OPEs, HFRs and phthalates. After hands, air was central to the networks of lower molecular weight compounds (e.g., phthalates) and dust was central to the networks of higher molecular weight compounds, (e.g., PBDEs). We interpretted these results to indicate that hands transport chemicals from surface to surface, leading to non-unique chemical profiles on all surfaces sampled. This notion—of hands as agents of chemical transport—is consistent with the role played by hands touching surfaces as the mechanism of disease transmission.

Lamoree, VU University, Department Environment & Health / Department Environment & Health; P. Leonards, VU University, Institute for Environmental Studies / Department of Environment and Health; C. de Wit, Stockholm University / Environmental Science and Analytical Chemistry; F. Tao, Stockholm University ACES; O. Sandblom, Stockholm University / Department of Environmental Science and Analytical Chemistry; M.M. Plassmann, J.P. Benskin, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; N. Wemken, National University of Ireland Galway / School of Physics & the Ryan Institute; M. Coggins, National University of Ireland Galway

Introduction Contact with indoor air and dust containing brominated flame retardants (BFRs), organophosphate flame retardants (PFRs), and perfluoroalkyl substances (PFASs) is an important human exposure pathway. This study tests the hypothesis that recent restrictions on such chemicals has led to reductions in their concentrations in indoor environments and iincreased levels of substitute chemicals. **Sampling and Analysis** Between December 2016 and February 2017, samples of indoor floor dust were taken from homes in: Amsterdam, Netherlands (n=11), Antwerp, Belgium (n=20), and Galway, Ireland (n=10). Dust samples were also collected from offices in Stockholm, Sweden (n=10) and Amsterdam (n=10). Indoor air samples were collected from the same 10 Galway homes and Stockholm offices. PBDEs, HBCDDs, TBBP-A, and a range of emerging BFRs (EFRs) and PFRs were determined in Galway air samples and in all dust samples, with the exception of those from Amsterdam for which only EFR data are available. In addition, concentrations of a number of PFASs were determined in dust from homes in Amsterdam (n=9), Antwerp (n=6), and Galway (n=10), dust from offices in Amsterdam (n=9), and Stockholm (n=10), as well as in air from Galway homes and Stockholm offices. PBDEs, EBFRs, and PFRs were determined using GC-MS, with LC-MS used to measure HBCDDs, TBBP-A, and PFAS. **Conclusions** Our results confirm the ubiquitous presence of BFRs, PFRs, and PFASs in European homes and offices and the continued existence of substantial differences in contamination levels and patterns between different EU states. Median concentrations of BDE-209, HBCDD, and DBDPE are markedly higher in Galway house dust than elsewhere. This may stem from Ireland applying flame retardancy regulations to soft furnishings that are similar to those in the UK, and differ to those applied in other EU countries. PFRs predominate in samples from Antwerp, Amsterdam, and Stockholm, and are at a similar level to BDE-209, HBCDD, and DBDPE in Galway. Offices in Amsterdam display the highest median concentrations of PFOA, PFOS, PFHxS, and PFBS. PFBS predominates amongst these PFAS in all but Stockholm office dust. This may indicate increased use of this short chain PFAS (and/or its precursors) in response to restrictions on PFOS and PFHxS. Likewise, the elevated DBDPE concentrations in Galway homes implies its increased use in response to restrictions on the use of Deca-BDE of which BDE-209 is the major component.

Levels of legacy and novel brominated Flame Retardants (BFRs) in Irish Human milk: Results from the Irish ELEVATE project 2016 - 2018

N. Wemken, National University of Ireland Galway / School of Physics & the Ryan Institute; C. Cellarius, University Hospital Galway / Obstetrics & Gynaecology; D. Drage, University of Birmingham / School of Geography, Earth & Environmental Sciences; K. Cleere, Coombe Womens & Infants University Hospital Dublin / Obstetrics & Gynaecology; J. Morrison, University Hospital Galway / Obstetrics & Gynaecology; S. Daly, Coombe Womens & Infants University Hospital Dublin / Obstetrics & Gynaecology; M.A. Abdallah, University of Birmingham / Division of Environmental Health and Risk Management College of Life and Environmental Sciences; C. Tlustos, Food Safety Authority of Ireland; S.J. Harrad, The University of Birmingham; M. Coggins, National University of Ireland Galway

This project aims to measure levels of flame retardants (FR) hexabromocyclododecane (HBCDD), polybrominated diphenyl ethers (PBDEs) and decabromodiphenyl ethane (DBDPE) in pooled samples of human breast milk from 92 Irish primiparas. Concerns regarding the impact of these chemicals on animal and human health eventually led to their classification as POPs, PBDEs and HBCDD have been listed as persistent organic pollutants (POPs) under the UNEP Stockholm Convention.Following bans and use restrictions for HBCDD and PBDEs, market demand resulted in manufacture of replacement FRs such as DBDPE. Analysis of human breast milk can provide a direct measurement of the human boody burden of POPs. The Food Safety Authority of Ireland performed a national survey on POPs in breast milk in 2013. The objective of this study is to replicate as far as possible the sampling strategy of this earlier Irish Biomonitoring study, and compare results to those of other European countries as well as previous Irish studies, to examine the evidence for possible temporal reductions in human body burdens in Ireland in response to actions (both legislative and voluntary) designed to reduce human exposure over the last decade. The sampling strategy was developed in line with that of the previous Irish bio-monitoring programme for POPs, and (with minor deviations) the 4thWHO UNEP protocols. Primiparas were recruited from the University Hospital Galway located in the west of Ireland and the Coombe Women's & Infants University Hospital located in Dublin between 2016–2018. Samples (30 - 60 mL) of breast milk were procured from participating primiparas and stored at -20 °C prior to pooling. Aliquots of pooled samples were extracted into 100 mL of dichloromethane (DCM) using pressurized liquid extraction (PLE) and subsequently cleaned by passing extracts through acid silica–packed columns. Samples were analysed via LC-MS/MS and GC/MS. Significant decreases are observed in concentrations of the PBDE congeners BDE-47 and BDE-153 ($p<0.01$,$p<0.05$) and some congeners are not detected (BDE-99 and BDE-100) when compared to results from the last Irish HBM in 2010, most likley reflecting the impact of voluntary and legislative bans on the use of these flame retardant containing products. Exposure estimates for nursing infant exposure to BDE-209 and BDE-47, were calculated following US EPA guidelines, and are below USEPA reference daily dose comparison guidelines.

564

Biomonitoring of indoor air toxins with C. elegans

P.J. Koskinen, S. Paavanen-Huhtala, K. Kalichamy, University of Turku / Biology; A. Pessi, S. Häkkilä, A. Saarto, University of Turku / Aerobiology; R. Mikkola, M.A. Andersson, Aalto University / Civil Engineering

Indoor air problems in schools and other public buildings weaken the health, well-being and working capacity of schoolchildren, their teachers and other exposed people. The aim of our project has been to develop biological tests based on the *C. elegans* nematodes, with which we could easily, reliably and reproducibly monitor overall toxicity caused by chemicals or microbial toxins, especially those that are present in the indoor air of moisture-damaged buildings. The nematodes have a well-developed chemosensory system, which helps them to find food and avoid pathogens. We have used transgenic nematode strains carrying fluorescent reporters driven by stress-responsive promoters and shown that exposure of these animals to indoor air toxins results in dose- and time-dependent fluorescent responses that can be quantitated by spectrometry or microscopy. By imaging we can evaluate the effects of toxins on fertility, motility and mortality of the animals and thereby distinguish between lethal and sublethal responses. Furthermore, since the *C. elegans* nematodes are transluscent, their imaging may give initial hints on whether the toxins have general effects or more specifically target the respiratory system, the nervous system or the immune system. Thus, as full organisms the nematodes provide several additional benefits as compared to other toxicity tests based on bacterial or eukaryotic cell populations, but further studies are still needed to validate their ability to distinguish between healthy and harmful buildings also under field conditions.

New Developments in the Science of vPvB and PBT Assessment (I)

565

What are currently the most important topics for the identification of PBT/vPvB substances in the view of the regulators?

J. Caley, European Chemicals Agency - ECHA / Evaluation; H. Ekholm, European Chemicals Agency ECHA; D. Hirmann, European Chemicals Agency (ECHA); A. Kapanen, European Chemicals Agency - ECHA; P. Lepper, ECHA-European Chemicals Agency / D.2 Classification and Prioritisation; J.R. Peltola-Thies, European Chemicals Agency - ECHA

The PBT Expert Group, having representatives from the EU Member State Competent Authorities (MSCA) the Commission, ECHA, industry and NGOs provides advice to PBT/vPvB assessments, updates the PBT/vPvT assessment approach as provided in ECHA Guidance and provides coordination and advice to the work on specific approach development topics, which have been identified by the group. In the autumn of 2018 a prioritisation activity for the current approach development topics of the PBT EG was undertaken. A total of 32 topics were scored in the online survey tool Webropol and 18 PBT EG members (out of a total 33) answered the survey. The scoring was based on perceived importance in terms of supporting and making the PBT/vPvB assessments more effective and on estimated human resource need and time for undertalking the work for the topic. The prioritisation activity resulted in the topics being listed according to importance and 9 topcis were assessed as being of high importance. The majority of the high importance topics are related to the bioaccumulation (B) assessment and they concern alternative means and methods for indicate bioaccumlulation potential for particular substance groups, where a comparison to the BCF criteria may not be the most representative way. It is perceived that there is a need to define other indicators, criteria and threshold values for the B assessment than the current ones of BCF and logKow. Other currently important topics concern clarifying the concept of weight-of-evidence and benchmarking in the PBT assessements and setting standards for these. The relatively new topic of practical expectations and limitations of chemical analysis in environmental fate testing for

REACH also gained a high score, as did the topic of specifying the issue of non-extractable residues (NER) in the guidance. A shift in focus from P- (persistence) to B endpoints has been an observed and the priority setting of the PBT EG reflects changes in priorities and experience gained over time. As the majority of the seats in ECHA's PBT EG are held by MSCA and other authorities, the priority setting of the approach development topics can be seen as reflecting the current focus on PBT issues by regulators. This indication may be of value for various stakeholders concerned with PBT issues and it may encourage increased collaboration on the developments that are currently believed to improving the identification of PBT properties in substances in the future.

566

Effects of adaptation of WWTP sludge on the biodegradation of emerging pollutants

B.A. Poursat, University of Amsterdam/IBED Institute / Institut for biodiversity and ecosystem dynamics; J. Dalmijn, University of Amsterdam / IBED; M. Braster, VU University Amsterdam / Department of Molecular Cell Biology; R. Helmus, University of Amsterdam / IBED; R.J. van Spanning, VU University Amsterdam / Department of Molecular Cell Biology; P. de Voogt, University of Amsterdam / IBED; J. Parsons, University of Amsterdam / Institute for Biodiversity and Ecosystem Dynamics

Regulatory determination of the persistency of organic chemicals is often based on the results of OECD ready biodegradability tests (RBTs). These tests, however, suffer from several problems that lead to a high variability of the results and, hence, to difficulties in their interpretation. The origin and history of the inocula is one of the major causes of that variability. Nowadays, it is evident that results of RBTs change over time as microbial populations apparently adapt to metabolise previously persistent chemicals. As such, there is a need to assess the influence of this process on biodegradability tests. In this study we assessed the extent of the inocula origin influence on the outcome of biodegradability testing. For this, we compared the biodegradation capacity of five different wastewater treatment plants across the Netherlands to eliminate carbamazepine, n-methylpiperazine, metformin, diclofenac and 4-chloroaniline. Most of these products can be considered as emerging pollutants and are environmentally persistent. In a second time, we used chemostat systems to expose activated sludge microbial communities to carbamazepine, n-methylpiperazine, metformin and 4-chloroaniline for several months under defined conditions. In both experiment, the biodegradation capacities of the inocula were assessed in biodegradation testing, following the OECD 310 guideline, and changes in community structure were followed by Illumina amplicon sequencing in time. Removal of tested chemicals and their transformation products were determined by GC-FID and LC-MS/MS. Results of these experiments show differences in the biodegradation capacity between the tested inocula. Short term exposure reduced these differences and increased the biodegradation capacity for metformin and 4-chloroaniline. Long term exposure of activated sludge to n-methylpiperazine in chemostat cultures leads to an enhanced biodegradation of this compound. These results will allow a better understanding of the relationship between microbial adaptation and biodegradation performance. Moreover, microbial communities exposed to metformin were able to degrade its known persistent transformation product, guanylurea, which is persistent in fresh water. Ultimately they will also allow more realistic predictions of their biodegradation in the environment compared to those obtained using standard testing protocols.

567

Microbial catabolism-based grouping enables read-across of the biodegradability of multiconstituents

R. Geerts, C.G. van Ginkel, Nouryon / Measurement and Analytical Science; C.M. Plugge, Wageningen University & Research / Laboratory of Microbiology

Ready biodegradability screening tests (OECD 301A-F and OECD 310) are used to assess the biodegradability of chemicals. In these test, a distinction between the biodegradability of an individual component of multi-constituent substances cannot be made because of the non-specific analysis used. REACH requires assessment of the biodegradability (persistency) of all constituents present at ≥ 0.1 wt% in a substance to determine their PBT/vPvB properties. Fatty acid amides (FAA) and alkylpolyglucosides (APG) are surfactants containing many constituents. Ready biodegradability for a number of these surfactants was demonstrated using the OECD screening tests. Testing the biodegradability of all constituents present in these surfactants is difficult or even impossible due to the large number of constituents and/or the unavailability of the individual constituents. Read-across is a non-testing method to predict biodegradability and considered to be a good alternative to experimental biodegradability data. The grouping of individual surfactant constituents for the read-across of biodegradation test endpoints is justified by using information on the catabolism of the microorganisms involved in the growth-linked biodegradation. FAA and APG degrading bacteria were isolated from inocula also used in ready biodegradability screening tests. The aerobic biodegradation pathways and the substrate specificities of the isolates capable of growing on these surfactants have been studied. It was shown that the (primary and secondary amide) FAAs and APGs were biodegraded starting with hydrolysis of the amide and glucosidic bond, respectively. The broad substrate specificity of the bacterial isolates involved in the first biodegradation steps and the subsequent rapid biodegradation of products formed allows read-across of ready biodegradability for all constituents present in the surfactants. In conclusion: Microbial catabolism-based grouping of constituents justifies read-across thereby enabling (improving) the ready biodegradability assessment of multiconstituent substances and UVCBs.

568

Non-extractable residues, an overlooked new hazard in the persistence assessment?

M. Telscher, Bayer AG Division CropScience/Environmental Fate / Development Environmental Safety; F. Schmidt, C. Leake, Bayer Ag

Non-extractable residues (NER) so called "bound residues" of plant protection products are formed *e.g.* in soil as a result of degradation processes. Due to their inherent nature, analyses and further assessments of bound residues are challenging. If the formation is due to microbial degradation processes the nature of the NERs is of course different to nature of original parent compound and release of NER is very slow in time and strongly correlated to degradation processes of the matrix (*e.g.* soil). In 2014 a new classification of non-extractable residues has been evolved and the non-extractable residues have been classified into three types of: NER type I: Entrapped, strongly adsorbed, no covalent binding NER type II: Covalently bound non-extractable residues NER type III: Biogenic bound residues ECHA published some guidance for the assessment of (Persistent Bio-accumulative and Toxic) PBT properties in 2017 (ECHA_2017_R.7b; ECHA_2017_R.7c; ECHA_2017_R.11). In addition in 2018 a discussion paper improving the interpretation of non-extractable residues (NER) in degradation assessment has been published by ECHA. I this discussion paper methods have been evaluated, how non extractable residues could be further experimentally analysed. In the regulatory view of ECHA the non-extractable residues are regarded as completely bioavailable and non-degraded residues in the regulation of general industrial chemicals and therefore they are regarded and handled in the risk assessment as parent substance if not shown otherwise experimentally. From our experiments it was concluded that the experimentally elucidation of non-extractable residues is highly sophisticated and therefore still challenging. However, even with soil destroying methods like the silylation, enzymatic digestion or digestion with 6 molar HCL at 110°C the main portion of bound residues will remain bound to the soil and therefore it could be concluded that this part is not bioavailable. The liberated non-extractable soil bound residues could not be assigned to bromoxynil nor any metabolites of bromoxynil. A small could be assigned to natural amino acids. Both results indicate that bound residues will not contribute to future risks or hazards because they are on one hand not bioavailable or on the other hand they have been converted to natural biogenic residues like natural amino acids. On the basis of these results an overlooked new hazard would not be foreseen.

569

From Bioavailability Science to Regulatory Persistence Assessment

C. Hughes, Ricardo Energy & Environment / Chemical Risk; L. Camenzuli, ExxonMobil Biomedical Sciences; A.D. Redman, Exxon Mobil Biomedical Sciences, Inc. / Toxicology and Environment Science Division; D.M. Saunders, Shell International / Departament of Ecotoxicology; E. Vaiopoulou, Y. Verhaegen, CONCAWE; S.A. Villalobos, BP / Global Product Stewardship

Bioavailability science has advanced significantly over the past 30 years. A recent article published after a SETAC special science symposium concluded that the science was sufficient for bioavailability concepts to be incorporated into regulation in order to provide for better risk assessments, through incorporation of risk-based measures of bioavailability and bioaccessibility. Under REACH, persistence (P) – as part of PBT/vPvB – assessment is largely hazard-based and does not recognise bioavailability concepts. This is exemplified by recent developments around characterisation and interpretation of non-extractable residues (NER). However, bioavailability is important as a lack of bioavailability prevents microbial degradation from occurring. Bioavailability of substances can also vary greatly depending on factors such as means of application, soil characteristics, extent of aging and source material. This presents difficulties in interpretation of P data and can lead to huge variation in derived half-lives, particularly from non-standard methods. Furthermore, it is arguable that the P assessment should focus on the (potentially) bioavailabile fraction of the substance in order to understand its intrinsic biodegradation potential and the recalcitrance of the fraction that may pose a risk to ecological receptors. This presentation aims to explore the potential for bioavailability science to be incorporated into regulatory P assessments, with a focus on phenanthrene as an example case. Phenanthrene represents an extreme case in that a vP classification has been proposed based on half-lives from certain field studies in soil, whereas in other studies the substance is demonstrated to be extensively degradable, particularly in water, and has even passed a ready biodegradability test. Considerations of bioavailability have been applied to the available P data with the aim of distinguishing the influence of lack of bioavailability from intrinsic biotransformation potential on derived half-lives. Particular focus has been placed on data generated according to the ECHA ITS, and how this relates to other data. Hazards and intrinsic biotransformation potential of the substance are also considered in assessment of risks posed from remobilisation of residual and NER fractions. Finally, implications for interpretation of weight of evidence and remaining uncertainties are explored, and recommendations for future assessments are proposed.

Communicating Science, Failures, Fortune and Risks to Improve the Value of Environmental Research to Society (I)

571
Data management system upgrade to ensure reasonable assurance level of non-financial reporting
R. Mankaa, INaB RWTH Aachen University / Institute of Sustianability in Civil Engineering; M. Bomheuer, RWTH Aachen University Institute of Sustainability in Civil Engineering / Institute of Sustainability in Civil Engineering; M. Traverso, RWTH Aachen / Institute of Sustainability in Civil Engineering
A constantly increasing number of investors and stakeholders are seeking for key information in the area of sustainability. This leads to an increasing demand for a transparent communication of non-financial data of companies. Sustainability reporting is a communication tool for stakeholders regarding a company's managerial performance and likelihood to continue business. External assurance of non-financial information is also increasingly relevant to ensure the quality and accuracy of information conveyed. In the case of Health, Safety and Environment (HSE) related information, to cope with increased disclosure expectations and to ensure high standard of data quality, a standardized data processing management system needs to be implemented. The goal of this paper is to evaluate the status quo of a company's HSE data processing system in order to identify challenges and opportunities to implement a data management system corresponding to a reasonable assurance level. The analysis considers environmental information related to energy input, water consumption, waste generation and Carbon dioxide emissions. The company under consideration in this analysis is a multinational performing integrated annual reporting and seeking reasonable assurance level for sustainability data. The outcome and methodology in this analysis can be implemented in other companies to improve and standardize their existing environmental management system in line with reasonable assurance level requirements. Although, the highest performing site scored 80% of available points indicating it already has satisfactory HSE data management implemented, close to 50% of sites investigated were found to have a weak data management system with urgent need for improvement. Results show that internal controls are implemented for over 90 % of all HSE aspects investigated, but only half of them meet the requirements and expectations of a reasonable assurance statement. There is therefore a great potential for improvement in the areas of data processing, documentation, internal communication and data validation at critical process points through the implementation of a reliable internal control system. In addition, the importance in adopting an IT system capable of standardizing the interfaces of data capture from external providers emerged as a critical aspect in upgrading the HSE data processing system. \n

Transparency within REACH?
M. Agerstrand, Stockholm University / Environmental Science and Analytical Chemistry; E. Ingre-Khans, Stockholm University; A. Beronius, Karolinska Institutet; C. Ruden, Stockholm University / Department of Environmental Science and Analytical Chemistry
According to REACH, the chemical industry must ensure that risks from chemicals they produce or import can be adequately controlled. Data on the chemicals' properties and uses, hazards and risks as well as instructions for safely handling, must be provided before chemicals are allowed on the market. The information is used to identify chemicals that warrant regulation. Thus, the registered data need to be reliable and relevant as well as transparently reported to ensure that chemicals of concern can be identified. In this presentation, results from four papers evaluating the transparency of REACH will be discussed. The papers report on lessons learned, and possible societal impact, from how the European Chemicals Agency and the chemical industry communicate scientific data for substances regulated under REACH. The results show that information that is used for concluding on hazards and risks of chemicals as well as industry's conclusions are reported in a semi-transparent manner and therefore difficult for third parties to fully scrutinise. This was in part due to the protection of confidential information but also related to ECHA's procedures for making information available as well as industry's reporting. Furthermore, industry is only required to summarise (eco)toxicity studies that are gathered for the risk assessment. Consequently, data based on industry studies that are not publicly available cannot be scrutinised by third parties. Thus, the system relies on studies being accurately summarised by the registrant although this was not always seen to be the case. Furthermore, the current framework for industry to evaluate (eco)toxicity studies and report data evaluations were found to be neither systematic nor transparent. Studies may not be evaluated based on their inherent scientific quality when the Klimisch method for evaluating data is used. Using the Klimisch method may also result in giving less weight to non-standard studies, such as many academic research studies, although non-standard studies could contribute with important information to the risk assessment. The transparency of data evaluations could be improved by using a framework that has clear criteria and guidance as well as a structured format for reporting data evaluations. This would support more harmonised and transparent data evaluations and encourage studies to be evaluated according to their inherent scientific quality rather than mere compliance with standardised guidelines.

573
Breaking down the barriers to science - Providing access to industry safety studies
A. Gladbach, Bayer AG, Crop Science Division / Research & Development, Disease Management; T. Babuscio, H. Boonstra, Bayer AG Crop Science Division; T. Cuenca Fernandez, Bayer AG; C. de Vulder, M. Griffiths, C. Gustin, Bayer AG Crop Science Division; R.J. Isemer-Kellner, Bayer Ag / Environmental Safety Ecotoxicology; U. Klages, K. Kunz, Bayer AG Crop Science Division; J. Lantz, Bayer US; S. Lauck-Birkel, J. Listello, A. Mertens, Bayer AG Crop Science Division; S. Myers, Bayer US; N. Pieper, N. Santos, D. Sargent, B. Stadtbäumer, Bayer AG Crop Science Division; G. van Duyn, Bayer US; M. Vogt, C. Morr, Bayer AG Crop Science Division
Crop protection products are among the most thoroughly researched and strictly regulated chemicals but people are worrying about their use and what it means for human health and the environment. Companies have not typically shared their safety studies with the public, which has often been a point of debate. Although some authorities make study summaries available on their website, information remains largely inaccessible to the public. Bayer is committed to restoring trust in the integrity of crop protection science and has decided to open up our science for everyone. By doing so, Bayer aims to foster an open, transparent, and science-based dialog around crop protection products. The transparency website aims to reach both interested layman and the scientific community. Visitors can access safety-relevant summaries and evaluations of active substance (a.s.) studies used in Bayer products and request full study reports. Disclosure is a continuous process, starting with a.s. registered in the EU and other countries (covering >90% of studies on an a.s. globally). Documents are redacted to comply with data privacy rights of Bayer's employees or contractors and to protect information related to details prone to commercial misuse. All blackened out data of course have been disclosed to and assessed by regulators. \n As a second pillar, videos, infographics and education material is provided to put regulatory science into context and to help break down barriers to science. Launched in 2017, Bayer's transparency initiative was the first in the industry to proactively enable access to safety-relevant information on its crop protection studies. Since its start, documents for 28 actives and many representative products have been made available. So far, more than 5000 site visitors and 17 requests of full study reports have been received. Transparency is the cornerstone of our philosophy as a life-science company. We fully support efforts to improve transparency around crop protection safety studies and recognize our responsibility to communicate how we assess our products' safety. We are reaching out for scientific collaboration to advance research in the fields of agronomics and public health. At the same time we want to level the playing field by providing background material and explanations, empowering non-scientists to be part of the debate around modern crop protection.

574
Ecopharmacovigilance of human medicinal products: Assessing and managing the real world risks resulting from patient use
J. Snape, AstraZeneca UK Ltd. / AstraZeneca Global Environment; S. Owen, AstraZeneca / Safety Health Environment; A. Boxall, University of York / Environment and Geography Department; D. Leverett, WCA-Environment Ltd; N. Budgen, AstraZeneca; S. Maynard, Astrazeneca UK Ltd; A. Nellis, SimOmics
Ecopharmacovigilance (EPV) is a developing science concerned with the detection, evaluation, understanding and prevention of adverse effects of active pharmaceutical ingredients (APIs) in the environment. In Europe and North America, a new regulatory submission or a line extension is normally accompanied by an Environmental Risk Assessment (ERA), but there is no regulatory requirement to monitor the environmental risks of medicines post-launch. Nevertheless, researchers globally continue to report instances of pharmaceutical residues in the environment, and publish new ecotoxicological studies on effects of pharmaceuticals on wildlife. To understand the significance of these emerging data and ensure that any potential risks are identified and managed appropriately, we have developed a process for EPV. This ensures that we can continue to understand the environmental risks associated with our products, and to manage them appropriately throughout the life of each product. This presentation will describe our EPV processes, how it works in practice and present a semi-probabilistic and spatially explicit environmental risk assessment for the patient use of several cardio-vascular and oncology APIs detected in the environmental surface waters. EPV is the environmental equivalent of pharmacovigilance and allows the environmental impact of ongoing patient use to

be managed though (i) routine literature monitoring for emerging data, (ii) the update of an ERA where emerging data challenge the original assumptions, and (iii) highlighting when APIs are detected in the environment at levels above published PNEC. EPV to date indicates that these instances represent < 2% of the total reported concentrations indicating site specific rather than generic risks that can be attributed to low flow, low dilution or poor wastewater treatment.

Improving transparency, consistency and efficiency of ecotoxicological teaching: launching the newly developed Open Online Textbook Environmental Toxicology

C. van Gestel, N. van Straalen, Vrije Universiteit Amsterdam / Ecological Science; T. Hamers, Vrije Universiteit Amsterdam / Department of Environment and Health; S. Moes, Vrije Universiteit Amsterdam / UBVU; M. Kraak, University of Amsterdam / IBED-FAME; J. Parsons, University of Amsterdam / IBED; S. Droge, University of Amsterdam; J. Hermens, Utrecht University / Institute for Risk Assessment Sciences; M.G. Vijver, CML Leiden University / Environmental Biology; N. van den Brink, Wageningen University / Dept of Toxicology; D. van de Meent, Radboud University / Department of Environmental Science; A.M. Ragas, Radboud University / Department of Environmental Science; A. Löhr, F. van Belleghem, Open University

Although several textbooks are available, teaching environmental toxicology in general seems to suffer from a lack of a well-elaborated, up-to-date and consistent textbook that covers all aspects of the field. As a consequence, every university is developing its own training materials in addition to a textbook, but only little of this material is available online. And materials online often are not consistent, lack novelty or do not cover the entire field. We took the initiative to develop an open online textbook on Environmental Toxicology that should cover the field in its full width, including aspects of environmental chemistry, ecotoxicology, toxicology and risk assessment. The initiative is sponsored by the Netherlands Ministry of Education. We aim at developing an online open access book on Environmental Toxicology that is useful for training at BSc, MSc and higher levels. The book is designed in a modular way, each module having clear training goals and flagged with a number of keywords. The book will also contain tools for self-study and training, like questions and exercises. With the publication of the open online book, we aim at improving quality, continuity and transparency of the education in environmental toxicology. We also want to make sure that fundamental insights on fate and effects of chemicals gained in the past are combined with recent approaches of effect assessment and molecular analysis of mechanisms causing toxicity. To guarantee quality of the book and associated training materials, each module is authored by 1-2 experts and reviewed by at least one international reviewer from outside the project team. An advisory board is involved in supervising the project, as well as educational advisors, while the project team serves as an editorial board. The project team, consisting of environmental toxicologists and chemists from six Dutch universities, also has involved colleagues from within the SETAC community to write modules that required specific expertise not covered. With that, we hope we can produce a book that is written and supported by SETAC, that is covering the entire field, and is useful for training within e.g. the SETAC Europe Certified Risk Assessor (CRA) programme. The publication as an open online book will allow continuous updating of the book, providing a possible role of SETAC in sustaining the book. At the SETAC Europe Annual Meeting in Helsinki we will launch our open online textbook on Environmental Toxicology.

Wright, Kings College London / MRC-PHE Centre for Environment and Health; K. Wyles, University of Surrey

Nano and microplastics (NMPs) are plastic particles of mixed shape that are present in air, soil, freshwater, seas, in biota, and in several components of our diet. NMPs come from a variety of sources, including products and textiles (use and breakdown), fisheries, agriculture, industry, waste, and others. Scientists, policy-makers and the public are becoming increasingly concerned about both the ubiquity of NMPs and the uncertainties surrounding their impacts, hazards and risks to our environment and to human health. Traditionally, the topic of NMPs has been addressed within separate scientific disciplines, but the consensus is increasingly that we need interdisciplinary approaches to understand the impacts and implications of NMP for the environment and society and to understand how to use this complex evidence base to help define policy and find solutions. Here we report on the process and outcome of a group of scientists writing a rapid Evidence Review Report for SAPEA (Science Advice for Policy by European Academies), as part of the European Commission's Science Advice Mechanism. The report, to be released in January 2019, offers a scientific perspective on the state-of-the-art knowledge about the implications of NMPs in nature and society and highlights the features and complexities of the topic. A unique aspect of this report is that it reviews relevant evidence from the social and behavioural sciences (e.g., on behaviour change, risk perception, media coverage), in conjunction with the current natural sciences evidence (e.g., on sources, occurrence, hazards, risks), which is crucial to designing effective policies. It also highlights uncertainties and knowledge gaps in order to inform appropriate future actions. Evidence from the environmental and health sciences, computer modelling, social, behavioural and political sciences are reviewed and presented together from a multidisciplinary perspective. The SAPEA Evidence Review Report informs a forthcoming Scientific Opinion by the European Commission's Group of Chief Scientific Advisors, which will contain policy recommendations and will be released in June 2019.

Scientific Advancements towards Risk Assessments, their Frameworks and the Implementation of Alternative Strategies to Animal Testing for Nanomaterials

Chronic effects of Safer by Design CuO NMs on young adults of the snail, Lymnaea stagnalis: influence of coatings and dispersants

V. Ricottone, Ramboll E&H / School of Life Science; T.F. Fernandes, Heriot-Watt University / Centre for Marine Biodiversity and Biotechnology, Institute of Life and Earth Sciences

Copper oxide nanomaterials (CuO NMs) are frequently employed for their antimicrobial properties in antifouling paints and other applications. Their extensive use can lead to contamination of aquatic ecosystems, where they can undergo further physico-chemical transformations. The main objective of this study was to investigate the chronic sublethal toxicity of different CuO NMs to the great pond snail *Lymnaea stagnalis*, a representative organism of the benthic ecosystem. It has become increasingly recognised that sublethal effects as measures of toxicity, are far more sensitive in the assessment of the potential impact of chemicals within an ecosystem. Chronic sublethal concentrations were selected based on the data gathered from acute exposure studies. Experiments aimed to investigate the effects on the reproduction and growth of *L. stagnalis* following exposure to Cu, either as ionic Cu ($CuSO_4$), pristine CuO NMs or "safer by design" CuO NMs coated with ponivinilpirrolidone (PVP), functionalised in either Milli-Q water or phosphate buffer (PBS). Results indicate a strong influence of the different dispersant used in the toxicity of CuO NMs. Indeed, when comparing the chronic lethal toxicity of all the CuO NMs tested at sublethal concentrations (0-200 μgL^{-1} Cu), findings showed an increase in toxicity due to the presence of PBS, which promoted further the agglomeration of the NMs. At that concentration range, no toxicity was recorded after exposure to pristine CuO NMs (H_2O). In contrast, CuO-PVP(PO_4^{3-}) NMs and CuO(PO_4^{3-}) NMs exposures exhibited a higher mortality after 30 days, with an LC_{30} estimated as 186 μgL^{-1} Cu for exposure to CuO(PO_4^{3-}) NMs and LC_{50} of 160 μgL^{-1} Cu for experiments with CuO-PVP(PO_4^{3-}). Findings from the sublethal endpoints indicated a direct link between the feeding rate inhibition and the decreased fecundity. This was confirmed by results gathered from the exposure to CuO-PVP(H_2O) NMs, where snails exhibited no alteration in feeding rate in response to increasing concentrations of the NMs and thus subsequently reproduction and growth were not affected in a concentration-response manner. This suggests that PVP, in absence of PBS, was able to mitigate the toxicity of the core CuO NMs in the long-term exposure.

578

Nanomaterial characterization - which parameters are needed from a regulatory point of view and how do we measure them?

E.A. Bleeker, RIVM / VSP; M. Visser, RIVM; M. Gonzalez, Organization for Economic Cooperation and Development; J. Shatkin, Vireo Advisors, LLC; S. Brown, The Chemours Company; A. Stanton, K. Moss, US EPA

In risk assessment, physicochemical characterization of the nanomaterial is an essential first step. This is particularly relevant where grouping, read-across and categorization of nanomaterials is used, i.e. where identification of similarities and differences is key. Within OECD a number of physico-chemical parameters have been identified as relevant to and important in the assessment of nanomaterials. The *Physico-Chemical Decision Framework to Inform Decisions for Risk Assessment* is the next step in the development of guidance for physico-chemical

characterisation and, where necessary, the development of new test guidelines. Together with the *Guiding Principles for Measurements and Reporting for nanomaterials: Physico-Chemical Parameters* it will assist users in deciding on physicochemical parameter(s) relevant to their nanomaterial and purpose, as well as identifying the most suitable technical method(s) and their reporting requirements to determine these parameters for their specific nanomaterial and purpose. Based on the framework and guiding principles, the presentation will discuss which physicochemical properties are relevant for characterization of nanomaterials from a regulatory point of view, address suitable – and less suitable – methods to test those properties, and identify future needs for standardization and harmonization.

579

The nanoGRAVUR framework for grouping of (nano)materials based on a harmonized set of material properties with 34 case studies

W. Wohlleben, BASF / Dept. of Material Physics & Dept. of Experimental Toxicology and Ecology

Nanomaterials are commercialized in a myriad of grades that are optimised in composition, size, shape, coating for specific applications. As the scope of the different reporting and registration schemes in EU countries, in the USA and Canada includes nanoforms of widespread materials, the need arises to evaluate if the different grades can be grouped for risk assessment purposes. Additionally, there is necessity to ensure the safe use of innovative nanomaterials early during R&D, ideally by read-across without animal testing. The project nanoGRAVUR (BMBF, 2015-2018) developed a framework for grouping of nanomaterials. Different groups may result for each of the three distinct perspectives of Occupational, Consumer and Environmental safety. Each is assessed by a risk matrix that integrates hazard and exposure indicators. The indicators are harmonised between the three perspectives and are based: · tier 1 on intrinsic physical-chemical properties (what they are) or GHS classification of the non-nano form (human tox, ecotox, physical hazards); · tier 2 on extrinsic physical-chemical properties, release from nano-enabled products, in-vitro assays with cells (where they go; what they do); · tier 3 on case-specific testing, potentially in-vivo studies to substantiate the similarity within groups or application-specific exposure testing The methods developed by nanoGRAVUR fill several gaps highlighted in the Steinhäuser & Sayre (2017) reviews, and are useful to implement both the ECHA concept of nanoforms as well as the EPA concept of discrete forms. Case studies include families of Fe_2O_3, SiO_2, CeO_2, organic pigment, ZnO, Cu, TiO_2 (nano)forms. Nano-enabled products included cardboard, automotive coatings, cements, plastics. Benchmark nanomaterials and benchmark nano-enabled products are essential to achieve reproducible groupings across different labs with slightly differing equipment (e.g. for dustiness, sanding, dispersion stability, reactivity). Furthermore, benchmark materials span the dynamic range of each property (often about three to five orders of magnitude), and thus help to assess the relevance of any dissimilarity between different nanoforms.

580

The GRACIOUS draft Framework for the Grouping of Nanomaterials in order to streamline risk assessment and decision making

V. Stone, Heriot Watt University / IB3; E.A. Bleeker, RIVM / VSP; T.F. Fernandes, Heriot-Watt University / Centre for Marine Biodiversity and Biotechnology, Institute of Life and Earth Sciences; J. Friesl, Yordas; D. Hristozov, Green Decisions; N. Jeliazkova, IdeaConsult Ltd; H. Johnston, Heriot Watt University / Life Sciences; F. von der Kammer, University of Vienna / Environmental Geosciences; A.G. Oomen, National Institute for Public Health and the Environment RIVM; H. Rauscher, European Commission - Joint Research Centre / Nanobiosciences; D. Spurgeon, Centre for Ecology & Hydrology; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology; S. Vazquez, ACONDICIONAMIENTO TARRASENSE (LEITAT TECHNOLOGICAL CENTER) / Sustainability Division; S. Stoycheva, Yordas; A. Vilchez, LEITAT; W. Wohlleben, BASF

Nanomaterials exist in a variety of nanoforms characterised by differences in properties such as size, shape or coating. In order to reduce the need to assess risk on a case-by-case basis, the GRACIOUS project will develop a framework that groups nanoforms together. The initial steps require basic existing or predicted information relating to the purpose of grouping (e.g. regulatory risk assessment or product innovation), the physicochemical properties, the intended uses and the potential releases of the nanoform(s). The GRACIOUS framework then provides a structure that uses this basic information to formulate hypotheses that explain why certain nanoforms can be grouped in relation to a specific hazard endpoint. These hypotheses consider information about; · what the nanoforms are (physicochemical characteristics), · where they go (in the environment, within the body), · what they do (hazard), and · the intended use (life cycle stages that result in release and exposure). The framework allows identification of whether the nanoform(s) align with a range of evidence based **well defined hypotheses**, for which the risk implications are clear. If the nanoform does not fit, then the framework guides the user through generation of a **user defined hypothesis** for grouping. The justification whether a grouping hypotheses applies to a specific (group of) (nano)form(s) is investigated via a tailored Integrated Approach to Testing and Assessment (IATA). The IATA guides the user through identification of relevant existing information, *in silico* and testing needs. In this manner, the GRACIOUS framework facilitates scientifically sound risk decision making for nanoforms, while minimising case-by-case testing. *Acknowledgement* – GRACIOUS is funded by the European Commission, Grant Agreement 760840.

581

Towards validating nanomaterial predicted environmental concentrations from SimpleBox4nano using the NanoFASE spatiotemporal multimedia fate model

J.T. Quik, RIVM / DMG; S. Harrison, NERC Centre for Ecology and Hydrology / Environmental Contaminants; J. Slootweg, RIVM / DMG; J.A. Meesters, RIVM / VSP; V. Adam, EMPA Technology & Society Lab / Technology and Society Lab; J. Keunen, TNO; S. Lofts, Centre for Ecology and Hydrology / Shore Section; W. Peijnenburg, RIVM / Center for Safety of Substances and Products

For prospective environmental risk assessment the predicted environemntal concentration (PEC) is not based on measurements but on calculations using modelling tools for estimating a substances release and fate in the environment. One of such tools is the screening level multimedia fate model SimpleBox. This model has recently been adapted for use with nanomaterials (SimpleBox4.0-nano (SB4N)), because nanomaterials require the inclusion of some physico-chemical processes such as agglomeration and dissolution to describe their fate in the environment. Although SB4N has undergone thorough testing, i.e. of its sensitivity to the defining nanospecific parameters, it remains unknown to what degree the steady state approach to modelling background concentrations compares to the expected temporal and spatial variability of nanomaterial PECs. With the recent development of the spatiotemporal multimedia fate model within the NanoFASE project such a comparison is now possible. The study of these two modelling approaches has two goals, first to indicate if the screening level PEC is a valid PEC at the regional scale and second if any further adaptions are required in order to improve the predictability of the model for nanomaterials. The SB4N and NanoFASE (NF) multimedia fate models where applied to the same spatial scenario: the Thames catchment. SB4N using minimal spatial resolution for a screening level exposure assessment and the NF model with much more spatiotemporal detail (5x5km grid). Overall the results show the expected outcome of steady state concentrations using a big mixed box. On the one hand for the water compartment the singular mixed box approach slightly underestimates the PEC in water. This can be mended by dividing the water compartment into two based on the distribution of nanomaterial emission to up and downstream streams. On the other hand, because of the PECs being at steady state, a compartment that acts as a sink, will continue to accumulate a lot of nanomaterials. This is the reason why the PEC from SB4N in soil is so much higher than the soil PEC from the NF model after one year.

582

Surface hydrophobicity of nanomaterials as surrogate of the Kow approach: a test method by JRC based on the binding affinity to engineered collectors

A. Valsesia, European Commission DG Joint Research Centre; S. Gottardo, P. Colpo, D. Gilliland, J. Riego Sintes, European Commission - Joint Research Centre

Information on physicochemical properties influencing the fate and behaviour of chemicals in the environment or their toxicokinetics in the human body is crucial for chemical risk assessments in any regulatory context and jurisdiction. Several regulations, including REACH, require reporting the octanol/water partitioning coefficient (Kow), an indicator of the fate and transport of a chemical in the aquatic compartment and a key parameter of any environmental exposure model estimating sorption to soil and sediment, bioavailability and bioconcentration/bioaccumulation in aquatic organisms. Kow also plays a role in (eco)toxicity predictions, e.g. in (Q)SAR modelling. It has been explained in the scientific literature that (insoluble) nanoparticles, due to their colloidal behaviour, cannot reach the thermodynamic equilibrium when partitioning between the octanol and water phases. For this reason, the use of Kow in nanomaterial risk assessment may lead to erroneous conclusions and scientists are investigating more appropriate fate predictors for nanospecific environmental exposure models. The OECD Working Party on Manufactured Nanomaterials (WPMN) concluded that the existing Test Guidelines for Kow determination are not applicable to (insoluble) nanoparticles and pointed out that a surrogate of the Kow may be necessary for obtaining information on nanomaterial environmental behaviour. This presentation illustrates a new test method for quantifying the polar component of the surface free energy of nanoparticles by measuring their binding affinity to rationally engineered hydrophobic and hydrophilic surfaces (collectors), via analysis of their adsorption kinetics by Dark-Field microscopy and using the XDLVO (eXtended Derjaguin Landau Verwey Overbeek) theory. The polar component of the surface free energy is a direct measurement of the surface hydrophobicity of solids. Determining the surface hydrophobicity of nanomaterials presents a reasonable alternative to the Kow for fulfilling regulatory information requirements, evaluating bioaccumulation potential (e.g. for PBT assessment) and predicting environmental fate and concentrations in exposure models, thus also providing a means to reduce animal testing.

Linking Models, Experiments and Measurements to Reliably Investigate the Environmental Fate and Effects of Hydrophobic Organic Contaminants and Mixtures (I)

583

Vertical profiles of hydrophobic organic contaminants (HOCs) in the sediment-water interface - assessing the impact of organic carbon cycling on HOC fate in the marine environment

I.E. Nybom, Stockholm University; D. Gilbert, NGI / Environmental Technology; N. Berrojalbiz, NGI; H. Arp, NGI / Environmental Technology; A. Sobek, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

Environmental fate of hydrophobic organic contaminants (HOCs) is closely linked to cycling of organic carbon. Organic carbon rich sediments often act as a sink for HOCs, but as primary emissions of legacy HOCs decrease, sediments may start acting as a secondary source to the water column. In this project, we hypothesize that organic carbon origin (i.e. terrestrial versus marine) and thus its sorption capacity, affects sediment-water fluxes of HOCs. To study the impact of organic carbon cycling on sediment-water fluxes of HOCs, four sites with in the Baltic Sea and a Norwegian Fjord, with different primary production regimes and relative contributions of terrestrial versus marine organic carbon, were sampled. Equilibrium passive samplers mounted on a recently developed sediment-water interface probe were used to sample freely dissolved HOCs. The organic carbon origin at the different sites was determined using stable carbon isotope signatures ($\delta^{13}C$). Data from the Norwegian site (representing low input of terrestrial organic matter) exhibited a high resolution profile of the sediment porewater ($C_{free\text{-}porewater}$)-bottom water ($C_{free\text{-}bottom\ water}$) interface for a wide range of HOCs (PCBs, PAHs, pesticides and chlorobenzenes). A strong concentration gradient between sediment pore water and overlying bottom water was observed for several PAHs indicating a potential flux of the chemicals from sediment to water. Further data will provide insights into effects of the different organic carbon cycling on HOC fate at the investigated sites.

584

Measurement of Freely Dissolved Concentrations of Alkylated PAHs in Sediment Porewater Using Solid Phase Microextraction with PDMS Fibers

M. Reininghaus, RWTH Aachen / Biogie 5; T. Parkerton, ExxonMobil Biomedical Sciences Inc. / Toxicology & Environmental Science; G. Witt, HAW Hamburg / Department of Environmental Engineering

Background: Application of the U.S. EPA equilibrium sediment benchmark approach for PAHs typically relies on total concentration (C_{total}) measurements of 18 parent and 16 alkyl polycyclic aromatic hydrocarbons (so-called 34 PAHs) in sediments. Following organic carbon normalization, these data are used for calculating the sum of PAH toxic units (∑TU) for assessing risks to benthic organisms. However, equilibrium partitioning assumptions that are inherent in this procedure may overstate potential risks which can be more reliably assessed using freely dissolved concentrations (C_{free}) in sediment pore water. Recent advances in equilibrium passive sampling methods (EPSMs) offer a promising alternative to C_{total} since bioavailability of sediment PAHs can be directly quantified via C_{free}. Currently, there is a growing consensus that C_{free} measurements provide an improved technical basis for sediment quality and risk assessment. However, to apply EPSMs reliable polymer to water partition coefficients are crucial. **Approach:** A laboratory (*ex-situ*) equilibrium passive sampling method was developed for evaluating the risk of parent and alkyl PAHs in sediments. The method relies on solid phase microextraction (SPME) with different silicone materials, i.e. polydimethylsiloxane (PDMS) coated glass fibers and hollow fibers. To date polymer-water partitioning coefficients are only available for parent PAHs for different polymer materials including PDMS. The first study objective was to determine PDMS-water partition coefficients (K_{PDMS}) for a range of alkylated PAHs. Based on the experimental values obtained, a Log K_{PDMS}-Log K_{ow} regression was developed and applied to estimate K_{PDMS} for a wide range of alkylated PAHs. The second objective was to apply this method on surficial sediments collected at seven sites in the Baltic Sea off the coast of Germany. The third goal was to compare C_{free} data from the *ex-situ* method to corresponding PAH measurements obtained at these same sites using *in-situ* deployment of PDMS passive samplers. **Results:** Reliable K_{PDMS} partition coefficients for alkylated PAHs were generated using 3 different PDMS coated fibers thereby extending use of EPSMs for this important class of contaminants. C_{free} obtained using *ex-situ* and *in-situ* approaches were comparable with mean values typically within a factor of 3. These results support further use of ex-situ based EPSMs which are quicker and likely cheaper than field deployments.

585

Biodegradation testing of volatile chemicals in water-sediment systems (OECD 308)

P. Shrestha, Fraunhofer- IME / Ecological chemistry; B. Meisterjahn, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / University of Vienna, Department Environmental Geosciences; C. Hughes, Ricardo Energy & Environment / Chemical Risk; P. Mayer, Technical University of Denmark / Department of Environmental Engineering; H. Birch, DTU Environment / Department of Environmental Engineering; J. Klein, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Ecotoxicology; E. Vaiopoulou, CONCAWE; D. Hennecke, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Ecological chemistry

OECD 308 guideline is used for biodegradation testing of chemicals in water-sediment systems. The guideline mentiones that it is not suitable for testing volatile chemicals and recommends a closed flask setup for testing slightly volatile chemicals. However, a clear guidance on system geometry and construction of the recommended test setup is lacking. In such tests, the choice of system geometry and sediment:water (S:W) ratio influences the partitioning and hence degradation of test chemicals. Additionally, it needs to be addressed how volatilisation should be considered in such tests during data treatment. Our objective was to adapt recently developed improved test setups to conduct OECD 308 test using four ^{14}C labelled volatile chemicals with different volatilisation range (phenanthrene < biphenyl < tetralin< decane). The data obtained were used to understand the underlying processes and suggest possible data treatment and data reliability measures.Two types of sediment were used. The test setup comprised of 50g (dry weight) sediment in a 500 mL vessel (Cylindrical, Ø= 5 cm) with location water with a S:W ratio of 1:3 and 1:4 for the high OC (Organic Carbon) and low OC sediment sample, respectively. The setup consisted of a permanently connected tenax tube and an internal NaOH trap to capture volatilized and mineralized fractions. The samples were applied with test chemicals using an appropriate co-solvent. Every week the headspace of samples was oxygenated to 18-20% oxygen saturation. At sampling the sample bottle was opened only after headspace stripping of air through the tenax tube. The tenax tube and NaOH trap were taken for analysis. The overlaying water was separated using a pipette and both sediment and water phase were further taken for extraction and further analysis. The sediment phase after extraction was allowed to dry and was combusted to determine the non-extractable residues (NER). The average mass balance was 91.3% ± 7.3 (S.D. N= 48), 99.4% ± 7.0 (N=46), 86.4 % ± 6.93 (N=50) and 93.2% ±9.9 (N=44) for phenanthrene, biphenyl , tetralin and decane studies. Generally, we observed that system geometry, S:W ratio used, had an influence on the partitioning of the test chemicals. Formation of biofilms on the overlaying water phase was very characteristic to closed setup applied with co-solvent (except sterile samples). We suggest reporting of procedural recovery, which improves the data reliability in the context of testing volatile chemicals.

Passive equilibrium sampling in aquatic biota: a glimpse on the bioaccumulation of hydrophobic organic compounds and its relation with trophic level

E. Rojo-Nieto, Helmholtz Centre for Environmental Research GmbH - UFZ / Department Cell Toxicology; M. Muz, UFZ - Helmholtz Centre for Environmental Research / Cell Toxicology; J. Watzke, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology; T. Wernicke, Helmholtz Centre for Environmental Research GmbH - UFZ; A. Jahnke, Helmholtz Centre for Environmental Research - UFZ GmbH / Cell Toxicology

Passive Sampling Devices based on polymers such as silicone, if operated in equilibrium mode, offer a superior approach to assess bioaccumulation than traditional exhaustive extraction, since they avoid the need for normalization of the total concentrations of hydrophobic organic compounds to the main sorptive phase, e.g. lipids. Recently, a new approach for equilibrium passive sampling in lean tissue has been proposed[1,2], allowing to reach equilibrium in biota tissue with low to medium lipid content, and thus to compare a set of species across trophic levels. In this study, a well characterized closed ecosystem has been selected, a small Swedish lake (Ången), and five different biota species were studied: crayfish, perch, roach, bream and eel. For crayfish and eel, the selected tissue was the muscle. For perch, roach and bream, the entire fish were analyzed. The samples were homogenized and the lipid content was determined. In order to calculate the trophic level, $\delta^{15}N$ was also determined. The homogenized tissues were sampled using silicone with three different thicknesses: 125, 250 and 350 μm to confirm equilibrium partitioning between the samples and the silicone, relocating the samplers 6 times per day over 5 days. The silicone was extracted, and the extracts were cleaned-up using EMR-Lipid cartridges (Agilent Technologies). The analysis and quantification of a wide range of compounds, including PAHs, PCBs, PBDEs, pesticides, musk compounds, sunscreens and antioxidants, were achieved with a gas chromatograph coupled to a high-resolution mass spectrometer (GC-HRMS Orbitrap Q-Exactive, Thermo Fisher). The present work accomplished, for the first time, the study of 160 compounds using passive equilibrium sampling in biota with different lipid content, from lean tissue to lipid-rich tissue. The equilibrium was confirmed for the compounds quantified in the different tissues, using silicone of different thicknesses. Despite the comparison of different tissues (muscle and entire body) from different species and the use of a standard $\delta^{15}N_{base}$ for calculations which might blur the interpretation of results, for some compounds we observed trends of increasing chemical concentrations with increasing trophic level. The aforementioned uncertanties will be reduced during the further implementation of the project, studying a complete set of samples from this ecosystem. [1] Rusina et al, 2017.

Monitoring of POP in biota versus aqueous passive sampling - a comparison in equal units

F. Smedes, Masaryk University, Faculty of Science, RECETOX / Environmental chemistry and modelling; J. Sobotka, Masaryk University, Faculty of Science, RECETOX / Research centre for toxic compounds in the environment; T. Rusina, P. Fialova, Masaryk University Faculty of Science RECETOX / Environmental chemistry and modelling; P. Carlsson, Norwegian Institute for Water Research; R. Kopp, Mendel University, / Department of Zoology, Fisheries, Hydrobiology and Apiculture (FA); B. Vrana, Masaryk University, Faculty of Science, RECETOX

Persistent organic chemicals pollutants (POP) such as PCB, hexachlorobenzene, organochlorine pesticides, PBDE, etc, are still present in surface waters and monitoring a number of them is required under the EU Water Framework Directive. Aquatic biota was selected as matrix for compliance monitoring of POP. However, concentrations of POP in fishes depend on size, age, sex, lipid content and physiological condition, as well as the season. For small water bodies around Europe, it is often not feasible to sample the same species, not even within a single catchment. The harmonization of biota monitoring thus presents a great challenge, and the WFD provided extensive guidance including correction for variations in dry-weight, lipid content, and trophic level (TL) of the monitored species. POP's concentrations in biota obtained for TL=4 by extra- or inter-polation using their log-linear dependence with TL, should be provided for checking compliance with environmental quality standard in biota (EQS_{biota}). The enrichment of stable isotopes ($\delta^{13}C$, $\delta^{15}N$) throughout the food web is commonly used to determine the trophic levels of species within a food web, while also generic values are applied, e.g. as listed at www.fishbase.org. Since POP accumulate in passive samplers their usage has been proposed as an alternative to chemical monitoring in biota. Passive sampling is frequently applied to estimate POP'sfreely dissolved concentration (C_{free}) in surface water and sediment pore water. Alternatively to C_{free}, uptake by passive sampling from various media, i.e. water, sediment and also fish tissue, can also be converted to a lipid based concentration ($C_{lip?media}$). These $C_{lip?media}$ are comparable in the same units with lipid based concentrations in fish tissue (C_{lip}) determined by conventional extraction. Such a comparison shows the differences in POP's thermodynamic potential between fish of various trophic levels and water. It also allows to assess if $C_{lip?water}$ determined by PS provides anequal level of protection compared to C_{lip}, obtained following the WFD guidelines. This work provides a basis for an informed decision on whether or not application of PS can comply with POP monitoring under the EU WFD. *Acknowledgement* - This work was supported by the Czech Science Foundation Grant No. GACR 15-16512S „Investigation of accumulation of persistent bioaccumulative toxic organic substances into aquatic organisms". \n\n

Analysis of attenuating factors for terrestrial food web biomagnification of cyclic volatile methylsiloxanes

K. Plotzke, Dow Chemical Company / Consumer Solutions; D.A. McNett, Dow; K.B. Woodburn, Dow / Toxicology and Environmental Research Consulting

Annex XIII of REACH indicates that a weight-of-evidence (WoE) determination on bioaccumulation (B) should consider "all available information" regarding this important environmental metric. Advances in the evaluation of a substance's ability to bioaccumulate or biomagnify in food webs have been published and are widely accepted by experts in this field, yet are not being consistently applied by regulators in PBT determinations. As indicated in the Stockholm convention, the critical concern regarding bioaccumulation is the issue of biomagnification, specifically substances that accumulate via the food web to progressively higher concentrations that may toxicologically impact top predators and humans. The key question is how to best predict biomagnification, a complex ecosystem phenomenon that is difficult to model in the laboratory. A laboratory BCF from water uptake is often used as a surrogate for biomagnification. But a BCF should only be considered a Tier 1, screening-level surrogate for biomagnification as it addresses only one level in the food chain and can be highly problematic in accurately characterizing dietary accumulation via the food chain for some substances. In this work, we examined the biomagnification of two volatile cyclic siloxanes, octamethylcyclotetrasiloxane (D4) and decamethylcyclopentasiloxane (D5), in aquatic food webs that terminated with terrestrial organisms and compared data to a recent terrestrial food web study. Field and laboratory data on D4 and D5 indicate that despite having positive biota/water ratios, these materials do not generally demonstrate biomagnification (TMF>1) through analyzed aquatic/terrestrial food chains due to the ability for aquatic organisms to metabolize D4 and D5 and for air breathing organisms to clear D4 and D5 through respiratory exhalation and metabolism.

Towards a Science-based Risk Assessment Framework for Nano- and Microplastic

589

Spatially resolved environmental emissions of seven commodity plastics in Switzerland

D. Wenger, Empa Swiss Federal Laboratories for Materials Science and Technology; B. Nowack, EMPA

While the knowledge on microplastic (MP) and macroplastic emissions is improving, uncertainties remain as to the local variations of MP concentrations. Large disparities are to be expected between residential, natural and agricultural areas among others, since specific uses and the corresponding emissions are dominating these environments. Identifying regions and compartments with potentially higher than average MP concentrations is crucial information to assess the possible risk in different settings. Moreover, the identification of possible hotspots may enable policy-makers to concentrate their efforts in more polluted areas. Using emission data available for Switzerland for seven different polymers, a regionalization of these emissions to a local scale is undertaken. The seven different polymers are: low-density polyethylene (LDPE), high-density polyethylene (HDPE), polypropylene (PP), polystyrene (PS), expanded polystyrene (EPS), polyvinyl chloride (PVC) and polyethylene terephthalate (PET). The resulting emissions are all expressed as probability distributions considering the confidence in the results. These emissions are then regionalized using different datasets as proxies for the considered emissions. The location of wastewater treatment plants (WWTP) and their level of treatment are used to model the release of MP and macroplastics from WWTP effluent and combined server overflow discharges. Maps of the population are used for the emissions of MP to outdoor and indoor air caused by private consumers and for the emissions of MP and macroplastics to residential soil caused by private consumers. Maps of the land use are used for the regionalization of further flows. High resolution maps of the quantiles of the emission distributions are then generated, giving best and worst case scenario estimates of the emissions of the different polymers to the environment. Different mapped datasets are considered as proxies to spread the modelled emissions over Switzerland, depending on the character of the emission. This regionalization will enable providing maps of MP and macroplastic emissions in Switzerland at high spatial resolution. These maps will show where the emission occurs and can act as first proxy to the plastic burden in Switzerland. Implementing fate processes based on these gridded datasets may then provide a more accurate estimate of the plastic pollution in Switzerland.

Microplastics in terrestrial systems: Evidence for new potential effects

A. de Souza Machado, Leibniz Institute of Freshwater Ecology and Inland Fisheries / Institute of Biology; E. Faltin, Freie Universität Berlin; W. Kloas, Leibniz-Institute of Freshwater Ecology and Inland Fisheries; M.C. Rillig, Freie Universität Berlin

Microplastics (plastics < 5mm, including nanoplastics < 0.1nm) are found globally due to fragmentation of large litter or direct environmental emission. Most of the research on this topic focused on impacts on aquatic systems, where several effects were reported. However, most of plastics arriving in the waters were produced, used, and disposed on land. It is within terrestrial systems that microplastics first interact with biota eliciting ecologically relevant impacts. We report here a suite of approaches including (I) a common garden experiment on the soil biophysical environment, (II) a greenhouse exposure of spring onions (*Allium fistulosum*) to 6 microplastics types, and (III) a climate chamber exposure of lettuce (*Lactuca sativa*) to 6 nanoplastic types. Such a combination of terrestrial models and microplastic particles allowed empirical evidence for new insights into the potential impacts of microplastics on unique properties of terrestrial systems. Microplastics altered the soil biophysical environment by changing the soil bulk density, water holding capacity, and the functional relationship between the microbial activity and water stable aggregates. Microplastics also triggered responses in spring onions' growth and traits, with significant changes in total biomass, above/below biomass ratio, root traits, and soil microbial activities. Effects of the tested polyester fibers and polyamide beads on plant traits and their function were the most pronounced. All the nanoplastic types significantly affected lettuce physiology (i.e. growth and biochemistry), with the magnitude depending on particle properties and exposure concentration (NH_2 termination and 50nm triggered the strongest effects). On this model, biochemical biomarkers suggested plastic uptake or close interaction of microplastics and lettuce roots. Confocal microscopy confirmed that most of the root fluorescence was due to nanoplastics strongly interacting with the roots surfaces. Our unprecedented results highlight the potential of microplastics to alter fundamental biophysical properties of the soil environment, which seem to be associated with responses on traits of spring onion. The smallest particles tested (nanoplastic) were also capable of causing significant plant toxicity. If extended to other models and plastic types, the processes unraveled here suggest that microplastics are relevant long-term anthropogenic stressors and drivers of global change in terrestrial ecosystems.

Fate and impact of nanoplastic particles and microplastic fibers on a stream biofilm-grazer system

A. Tlili, Eawag / Department of Environmental Toxicology; M. Holzer, B. Wagner, Eawag-Swiss federal Institute of Aquatic Science and Technology / Department of Environmental Toxicology; D.M. Mitrano, Eawag - Swiss federal

Institute of Aquatic Science and Technology / Process Engineering
Following the increasing global production of plastic, particulate plastics are increasingly detected in aquatic ecosystems, including fresh waters. Scientific information on their effects is therefore needed to evaluate the ecological and ecotoxicological significance of their occurrence in the water bodies. A better understanding of the trophic transfer potential of particulate plastics and its consequences are essential. Fate studies have identified the benthic compartment in the aquatic ecosystem as a target for the accumulation of particulate substances. In this study, we investigated the trophic transfer of nanoplastic particles and microplastic fibers (doped with a metal tracer which can be used as a proxy to more quickly and qualitatively evaluate plastic presence), from stream biofilms, a benthic microbial community, to a grazer upon dietary exposure. Biofilms were loaded with the plastic particles and fibers, and aquatic snails (*Physa acuta*) were allowed to graze on the contaminated biofilms for 14 days to assess the potential of plastic assimilation and consequent effects. Results showed that upon 24 hours of exposure, 60 % of the plastics added accumulated in the biofilms. This led to the alteration of the microbial composition and nutritive quality of the biofilms but did not impact their physiology or growth. The accumulated plastics in the biofilms were also transferred to the snails through their diet. However, no significant differences in the feeding rate of the snails was observed. On the other hand, growth rate of the snails feeding on the plastic particles and fibers was impaired and decreased by 30 ± 9 % in comparison to the controls. The reproductive output of snails, measured as the number of egg clutches, was also negatively affected when exposed to either nanoplastic or microplastic fibers. Indeed, snails feeding on control biofilms started to lay egg clutches on the fifth day of the experiment, while snails feeding on the contaminated biofilms did not reproduce at all. Due to ending the experiment, it was not clear if reproduction was only delayed or impossble for the exposed organisms. Overall, the present study confirmed an efficient transfer of particulate plastics and their negative impacts in an aquatic trophic chain, which can have consequences for trophic relationships and survival of invertebrates in aquatic ecosystems.

Toxicity of nanoplastics to marine organisms
M. Oliveira, RMS-TekebBio, LDA; I. Ferreira, University of Aveiro / Department of Biology; C. Ven�ncio, Department of Biology / Biology; M.A. Martins, University of Aveiro / Physics Department & CICECO; A.M. Soares, University of Aveiro / department of Biology & CESAM; I. Lopes, University of Aveiro / Department of Biology & CESAM, 3810-193 Aveiro
The presence of small plastic particles in the environment is currently recognized as a global issue of concern. Nonetheless, the amount of small plastic particles in the aquatic environment continues to increase, in part due to ongoing increases in the production of plastics. A large number of organisms are exposed to these particles and this exposure may cause a variety of effects and threaten individuals of different species, the ecosystems they live in and, ultimately, humans [1]. An increasing number of studies have been providing information on the effects of microplastics. However, limited information has been so far provided in terms of nanoplastics, particularly to marine organisms. This work aimed to provide data in terms of effects to marine producers and a primary consumer (rotifers) of 50 nm polymethylmethacrylate nanoplastics, a polymer that has not been a subject of research. Additionally, a literature analysis of the available studies in terms of nanoplastics to marine organisms was integrated to derive a 5th percentile value (HC5) of nanoplastics of the most studies polymer. The effects of nanoplastics on microalgae were assessed throughout a 96h exposure in static conditions, testing a concentration range up to 304 mg/L. The effects of nanoplastics (4.7, 9.4, 18.9, 37.5, 75.0 mg/L) on rotifers survival was assessed in 48-h survival assays. Median effect/lethal concentrations were determined for producers and consumer, respectively. Overall, primary consumers were more sensitive to nanoplastics.

593
Mimicking nanoplastic pollutants: study of their effects to biological systems
D. Magri, P. Sanchez Moreno, M. Veronesi, P. Pompa, A. Athanassiou, D. Fragouli, Istituto Italiano di Tecnologia
The presence of micro- and nanoplastics in the marine environment is raising strong concern since they can possibly have a negative impact on human health. The lack of appropriated methodologies to collect the nanoplastics from water systems imposes the use of engineered model nanoparticles to explore their interactions with biological systems, with results not easily correlated with the real case conditions. Herein, we present a strategy for the fabrication of pure nanoplastics, the investigation of their physicochemical interactions with other aquatic pollutants and the toxicity evaluation of the specific products. In particular, we present a top-down approach, which, starting from bulk scale materials, allows obtaining nanosized particles, mimicking a degradation pathway more similar to the one occurring under real environmental conditions. The process, based on the laser ablation of polymer films in water, allows fabricating nanoplastics without the use of chemicals and precursors. The study is focused on polyethylene terephthalate (PET) nanoplastics, a material largely diffused and mainly used in the food packaging industry. We prove that the chemical and physical properties of the as-produced nanoplastics present similarities to the ones expected to be present in the environment. After the evaluation of the stability in various biological media, detailed studies on the nanoplastics interaction with three representative acquatic pollutants (mercury metal ions, levofloxacin antibiotic and glyfosate pesticide) have been performed. We prove that the nanoplastics interact succesfully with all three pollutants. The study of their interactions with Caco-2 and THP-1 cell lines reveals the presence of the nanoplastics is not toxic for the cells in the short term. However, the metabolomics study performed reveals that there is a significant effect of the presence of the nanoplastics and of the nanoplastic-pollutants in the metabolism of the cells, proving the adverse effects that these nanopollutants can cause to the biological systems.

Simulating human exposure to indoor airborne microplastics using a Breathing Thermal Manikin
A. Vianello, Aalborg University / Civil Engineering Department - Section of Water and Environment; R.L. Jensen, Aalborg University; L. Liu, Tsinghua University / School of Architecture; J. Vollertsen, Aalborg University / Department of Civil Engineering, Section of Water and Environment
Humans are potentially exposed to microplastics through food, drink, and air. While the first two pathways have received quite some scientific attention, little is known about the latter. A crucial aspect of the presence of atmospheric MP is related to its likelihood of being inhaled and potentially reaching the alveoli of the lungs. To date, only a few studies have addressed the potential human exposure to airborne microplastics. The present study extends knowledge of indoor airborne MP exposure, composition, and size ranges, providing data on particles (including fibres) of sizes down to 10 μm. We addressed the exposure of humans to indoor airborne microplastics using a Breathing Thermal Manikin (BTM). Three apartments located in Aarhus (Denmark) were investigated collecting a total of mine samples, then analysed using FPA-μFTIR-Imaging spectroscopy followed by automatic analyses (MPhunter) down to 10 μm particle size. All samples were contaminated with microplastics, with concentrations between 1.7 and 16.2 particles m^{-3}. Synthetic fragments and fibres accounted, on average, for 4% of the total identified particles, while nonsynthetic particles of protein and cellulose constituted 92% and 4%, respectively. Polyester was the predominant synthetic polymer in all samples (81%), followed by polyethylene (5%), and nylon (3%). Fragments resulted more abundant than fibres in the samples (87% and 13% respectively). Microplastics were typically of smaller size than nonsynthetic particles, and a correlation between MP size and their abundance was recorded ($R^2 = 0.702$), highlighting that the smaller the size, the higher the concentration in the air. As the smallest identified microplastics can be inhaled and possibly even reach the alveoli of the inner lungs, these results stress the potential direct human exposure to microplastic contamination via indoor air.

State of the Science on Emerging and Novel Poly- and Perfluoroalkyl Substances (PFASs) (II)

595
Global transport of perfluoroalkyl acids via sea spray aerosol
J. Johansson, Stockholm University / The Department of Environmental Science & Analytical Chemistry (ACES); M. Salter, Stockholm University / Department of Environmental Science & Analytical Chemistry (ACES); J.A. Navarro, Stockholm University / The Department of Environmental Science & Analytical Chemistry (ACES); C. Leck, Stockholm University / Department of Meteorology; D. Nilsson, Stockholm University / The Department of Environmental Science & Analytical Chemistry (ACES); I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry
Findings suggest that the long-range atmospheric transport of perfluoroalkyl acids (PFAAs) may be substantial, but it is currently not known what the main sources of atmospheric PFAAs are or how the compounds are transported in the atmosphere. PFAAs are present throughout the world’s oceans, which are currently assumed to be the final “sink" of PFAAs in the environment. However, sea spray aerosols have been suggested as a potential vector for ocean-to-atmosphere transport of PFAAs. We have used a laboratory system to study water-to-air transfer of 11 PFAAs via sea spray aerosol (SSA). SSA was generated from artificial seawater spiked to a concentration of approximately 10 ng/L for each studied substance. We observed significant enrichment of all PFAAs relative to sodium in the SSA generated. The highest enrichment was observed in aerosols with aerodynamic diameter < 1.6 μm, which had aerosol PFAA concentrations up to 62000 times higher than the PFAA water concentrations in the chamber. In surface microlayer samples collected from the sea spray chamber, the enrichment of the substances investigated was orders of magnitude smaller than the enrichment observed in the aerosols. In experiments with mixtures of structural isomers, a lower contribution of branched PFAA isomers was observed in the surface microlayer in relation to the bulk water. However, no clear trend was observed for the comparison of structural isomers in SSA and bulk water. Using the measured enrichment factors of perfluoroctanoic acid and perfluorooctance sulfonic acid versus sodium we have estimated global annual emissions of these substances to the atmosphere via SSA as well as their global annual deposition to land areas. The total annual flux of PFOA and PFOS to the atmosphere via SSA

estimated in this study is comparable to or exceed previous emission estimates for other potential sources of these substances to air. About 3% of the PFOA and PFOS aerosolised as SSA is transported and deposited to land areas. Our experiments suggest that SSA may currently be an important source of these substances to the atmosphere and, over certain areas where SSA deposition is important, a significant source to terrestrial environments.

Are bioaccumulation factors useful for regulation of PFOS in aquatic ecosystems?
K. Bowles, RPS Australia Asia Pacific / RPSPM; J. Beyer-Robson, NSW Office of Environment and Heritage
Accounting for bioaccumulation in regulation is complex and different jurisdictions have adopted varying approaches. Perfluoroalkyl acids (PFAAs) are a group of chemicals that bioaccumulate, but by a different mechanism to the better-understood chlorinated pesticides. In particular, perfluorooctane sulfonate (PFOS) bioaccumulates in aquatic fauna, but apparently due to protein affinity, rather than lipophilicity. Franklin (2016) described limitations of measures of biomagnification for PFOS, calling into question the use of BAFs in a predictive way. Here we summarise BCFs and BAFs in organisms with gills, particularly those reviewed by Ding and Peijnenburg (2013) and Moermond et al. (2010). The summarised BAFs varied over three orders of magnitude. Trophic level did not appear to be a good indicator of the variability, but there was a suggestion that sediments play a part in bioaccumulation of PFOS, as previously observed by Martin et al. (2004). The variability in BAFs and lack of clear understanding of the mechanism controlling bioaccumulation hinder the use of these metrics for regulatory purposes. Examples of two different regulatory approaches are provided to highlight issues with using BAFs to derive conservative criteria. Moermond et al. (2010) calculated water-based criteria for protection of birds and mammals by using BCFs and BMFs to extrapolate from toxicity thresholds to a concentration in water. In order to derive a conservative guideline value using this top down approach, it is appropriate to use a high estimate of BCF and BMF. Environment and Climate Change Canada [7] used a BAF to extrapolate from a water concentration, to a concentration in fish tissue that would be protective of the fish. Using this bottom up approach, it would be desirable to use a low estimate of BAF in order to derive a conservative guideline value. Although the approaches from RIVM and ECCC aim to protect different values, the need to select either a high or a low estimate of bioaccumulation is interesting and worthy of discussion. Both the large variability in bioaccumulation metrics for PFOS in aquatic organisms, and the uncertainty in mechanisms controlling bioaccumulation, suggest that factors such as BAFs and BCFs need careful consideration when deriving aquatic criteria. For some purposes, such as protection of fish from exposure by bioaccumulation, using tissue-based toxicity values will prove useful if more data become available from future testing.

598
Prenatal exposure to PFOS and PFOA in a Catalan pregnant women cohort.
J. Rovira, Universitat Rovira i Virgili / School of Medicine IISPV; M. MARTÍNEZ RODRÍGUEZ, M. Espuis, Universitat Rovira i Virgili; R.P. Sharma, Universitat Rovira i Virgili / Chemical Engineering; M. Nadal, V. Kumar, Universitat Rovira i Virgili / School of Medicine, IISPV; D. Costopoulou, I. Vassiliadou, L. Leondiadis, NCSR Demokritos; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health; M. Schuhmacher, Rovira i Virgili University / Departament d Enginyeria Química
The perfluoroalkylated substances (PFASs) perfluorooctane sulfonic acid (PFOS) and perfluorooctanoic acid (PFOA) have been widely studied for their constant use in recent decades and their persistency, bioaccumulation and toxic properties. The aim of this study was to assess the prenatal exposure to PFOA and PFOS from a cohort of pregnant women in Reus (Catalonia, Spain). These chemicals were biomonitored from maternal blood during the first trimester of pregnancy, at delivery, and also from cord blood. Dietary exposure to PFOA and PFOS were determined using food frequency questionnaires and water intake, as well as the levels of these compounds previously analysed in foodstuff of Catalonia. In addition, the exposure levels of PFOS and PFOA were determined in indoor dust and air, using activity profiles of women. Finally, a physiological-based pharmacokinetic (PBPK) model was applied in order to: 1) establish the prenatal exposure of the fetus/child, and 2) evaluate the adjustment of exposure assessment (dietary and environmental) and biomonitoring results. Mean plasma levels were 0.45, 0.13 and 0.12 ng/mL for PFOA and 2.93, 2.21, and 1.17 ng/mL for PFOS at the first trimester, at delivery, and in cord plasma, respectively. Transplacental transferences of PFOS and PFOA of around 70% and 60%, respectively, regarding maternal levels at first trimester were observed. Similarly to previous studies, a temporal decrease trend in PFOA and PFOS blood levels were noticed, when the current results were compared with those of studies performed ten years ago in the same area. Dietary intake is the main route in our cohort. Fish and seafood are the main dietary contributors in this cohort of pregnant women. Maternal age (lower levels in younger mothers), parity (lower PFASs levels in women with previous children), and maternal country of birth (higher levels of PFASs in Spanish mothers) are determinants of the levels of PFASs, especially PFOA. Probabilistic calculations of fetal exposure were estimated by forward internal dosimetry using physiologically based pharmacokinetic (PBPK) model, and Monte-Carlo simulation. The physiological and chemical-specific parameters were adapted from the adult human model and modified for the fetuses and mothers, as a function of the gestational period. This is an important issue to establish the exposure in critical windows periods such as fetal development to PFASs, but also to other endocrine disrupting chemicals.

599
PFAS research within the US Environmental Protection Agency: Results to date and future direction
A. Gillespie, U.S. Environmental Protection Agency / Atlantic Ecology Division
Per- and polyfluoroalkyl substances (PFASs) are a growing concern among many communities in the US due to increasing reports of potential human exposures. The science required to protect public health and the environment from PFAS exposure cuts across many applications and disciplines. The risk assessment/risk management paradigm provides a useful means to assess the state of the science available for informing decisions, and to identify gaps in knowledge needed to support risk management. US EPA's initial scoping of information available for assessing and managing PFAS risks revealed deficiencies in all key areas of the risk paradigm including hazard and toxicity (there are likely hundreds of PFAS in the US environment, and most lack sufficient suitable toxicity information for informing understanding of the potential for human or ecological effects); exposure (information about different PFAS sources, fate and transport, and human and ecological exposure is sparse, both spatially and temporally); and suitable treatment and remediation approaches (there is little information on effective methods and costs for treating or removing different PFAS from drinking water, groundwater, wastewater, air, soils, and sediments). US EPA is conducting an integrated set of research activities aimed at filling gaps in our current ability to conduct scientifically rigorous risk assessment and risk management activities. This research program is designed to address these data gaps and enable stakeholders to begin making effective decisions for identifying and mitigating risk from PFAS in the environment. Many different entities have an interest in – and are actively conducting – research to address PFAS, and so there is a substantial opportunity to advance PFAS science by improved coordination and collaboration. The purpose of this presentation is (1) to provide an overview of US EPA's overarching PFAS research program, with a focus on recent advances and ongoing activities, and (2) look for opportunities to collaborate with other organizations to advance the science needed to understand and manage risk from PFASs.

Contaminated Sediments: an Understudied Environmental Compartment (II)

601
Toxic floods - Impacts of remobilized endocrine disruptors from sediments in rainbow trout (Oncorhynchus mykiss)
A. Mueller, RWTH Aachen University / Chemicals and Product Safety; N. Markert, North Rhine Westphalian State Agency for Nature, Environment and Consumer Protection (LANUV NRW) / Ecotoxicology; K. Leser, RWTH Aachen University / Institute for Environmental Research (Biology V); S.E. Crawford, RWTH Aachen University / Institute for Environmental Research, Dept. of Environmental Analysis; H. Schuettrumpf, RWTH Aachen University / Institute of Hydraulic Engineering and Water Resources Management; H. Segner, University of Bern / Centre for Fish and Wildlife Health; M. Brinkmann, University of Saskatchewan / School of Environment and Sustainability and Toxicology Centre; H. Hollert, RWTH Aachen University / Institute for Environmental Research
Studies all around Europe have demonstated using *in-vitro* biotests that endocrine-disrupting chemicals (EDCs) can accumulate at high concentrations in river sediments ranging from 0.02 to 55 ng estradiol equivlanents per gram. Even small concentrations of EDCs can significantly interfere with the sexual development of fish, leading to the feminization of male fish and thereby adversely affect the reproductive success of whole populations. However, remobilization of sediment-bound EDCs e.g. due to bioturbation or re-suspension during flooding and associated effects on aquatic wildlife as fish is yet poorly understood. Therefore, the main objective of this study was to evaluate the risks of sediment-bound EDCs during flood events regarding a) whether they might become bioavailable to fish, i.e. rainbow trout (*Oncorhynchus mykiss*), when sediments are resuspended and b) if uptake consequently leads to negative effects in those organisms. Juvenile

rainbow trout were exposed over 21 days in groups of 24 individuals to six different treatments including 1) municipal tap water as water control; 2) sediment from Ehrenbreitstein (Rhine river, Germany) which shows low contaminant concentrations; 3) sediment from the Luppe river (Germany) highly contaminated with EDCs; and 4-6) three dilutions of Luppe sediment with Ehrenbreitstein sediment: 1:2, 1:4, and 1:8. Sediment (5 g/L dry weight) was constantly re-suspended using submersible pumps. Nonylphenol (NP, water control: 6 ng/L; Luppe: 1050 ng/L) and estrone (water control: 0.1 ng/L; Luppe: 7 ng/L) were detected by means of passive sampling (Chemcatcher) and subsequent LC MS/MS analysis. Moreover, high concentrations of NP were detected by LC MS/MS in bile samples ranging from 0.5 $\mu g/mL_{bile}$ (water control) up to 984 $\mu g/mL_{bile}$ (Luppe), whereas NP concentrations in blood samples were about 1000- fold lower. Total estrogenic activity identified by the yeast estrogen screen in bile of fish exposed to Luppe sediment was positively related to bile NP concentrations. Vitellogenin (Vtg) content in mucus samples of trout after 21 days of exposure to Luppe sediment was significantly higher as before exposure. Our findings demonstrate that sediment bound EDCs were remobilized, bioavailable and readily taken up by fish. Adverse effects are likely based on the induction of Vtg. Currently conducted studies on changes of estrogen-responsive genes will help to evaluate how pronounced these effects are.

Are Diffusive Gradients in Thin Films (DGTs) useful predictors of the ecological effects of Cu in the field?

S.C. Udochi, A. Grant, University of East Anglia / School of Environmental Sciences

For its ability to measure the concentrations of free metal ions and labile complexes which may be relevant to biota uptake, Diffusive Gradients in Thin Films (DGT) has been projected as a useful tool to predict metal bioavailability and toxicity in aquatic systems. However, most studies establishing this relationship to date have relied on spiked sediments and/or measured metal bioaccumulation, which may not reflect ecological effects occuring in actual field sites. In this study, we extended the use of DGT to naturally-contaminated field sediments, and compared its predictive capability with traditional metal measurements including total metals, dilute-acid extractable metals, and measures based on the Equilibrium Partitioning Model (EqP). We deployed the DGT probes along a Cu contamination gradient in the Fal and Hayle estuaries, South West England, and assessed ecological effects using the pollution-induced tolerance of nematode communities as an endpoint. Total concentrations, extractable metals, and traditional EqP normalisations poorly predicted effects of Cu to the nematode communities at our sites. Conversely, the DGT-concentrations were correlated with observed effects, as well as porewater metal concentrations previously determined at the sites. DGT-Cu measured in the overlying water, 1-2 cm above the Sediment-Water Interphase (SWI), appeared to be more strongly related with effects than Cu in the surface sediments (1-2 cm below SWI). Although our results corroborate previous laboratory studies performed with spiked sediments, we note the relatively low dynamic range of DGT-concentrations measured in the field. This narrow range could considerably limit the applicability of DGT in the assessment of moderately-contaminated sites where effects might be occuring, thus challenging the usefulness of the technique in deriving sediment guideline values. Our work confirms the importance of field studies in ecotoxicology, highlighting the shortcomings of laboratory assays in creating realistic exposure conditions. We conclude that DGT, within its current use, is at best suited for assessing the relative bioavailability of dissolved metals between given sites.

Effects of Oil Sands Bitumen Exposure in Aquatic Ecosystems: An Integrated Ecotoxicological Approach

D. Nunes Cardoso, CESAM, University of Aveiro / department of Biology & CESAM; D. Campos, University of Aveiro / Biology Department and CESAM; A.R. Silva, University of Aveiro / Dept.of Biology & CESAM; S. Goncalves, Department of Biology & CESAM - University of Aveiro / Department of Biology and CESAM; P. Silva, Universidade de Aveiro / Biology Department and CESAM; A.L. machado, Universidade de Aveiro / CESAM Department of Biology; J. Pestana, CESAM & University of Aveiro / Biology; A.C. Rodrigues, Department of Biology & CESAM - University of Aveiro / CESAM & Biology; F. Simao, Aveiro University & CESAM; A.M. Soares, University of Aveiro / department of Biology & CESAM; F. Wrona, Alberta Environment and Parks / Department of Biological Sciences; S. Loureiro, Universidade de Aveiro / Biology

The Athabasca oil sands deposits in northern Alberta, Canada, are a naturally occurring mixture of bitumen, sand, clay and other minerals. Bitumen is a heavy and extremely viscous oil, which after mined and subsequently refined produces gasoline, diesel and other hydrocarbon-based products. Moreover, the naturally occurring Athabasca Oil sands deposits are a source of both physical and chemical stressors to local rivers that flow through the deposit. Physical stress to aquatic biota from natural bitumen results from hillslope erosion processes and slumping of material into the rivers, while chemical stress arises from bitumen-derived contaminants entering the waters. To fully understand the cumulative ecological effects of oil sands mining activities to aquatic ecosystem, in terms of water quality and associated biological structure and function, there is a need to previously evaluate the effects of naturally occurring bitumen in the aquatic environment. For that, a series of inter-related laboratory ecotoxicological assays were conducted using benthic and pelagic aquatic invertebrates exposed to oil sands material collected from four different sources in regional rivers. Organisms were sensitive to the presence of oil sands elutriates, especially to elutriates generated from bitumen collected in the banks of the Steepbank and Ells river, with effects on the life traits of *Daphnia magna*, *Physa acuta, Vibrio fischeri,* and *Dugesia tigrina*. When bitumen was mixed with sediment, it was also toxic to *Chironomus riparius,* which responded negatively bitumen samples with more bitumen content in sediments with a decrease in their body size, a delay on the emergence time, reduced total emergence and a decrease in the weight of imagoes. On a more complex approach, bitumen negatively affected natural communities tested in a mesocosms experiment by reducing the number of *Ephemera* sp. and *Chironomus* sp. that feed on fine sediment particles. The use of solid and elutriates bitumen samples, combined with a suite of representative species and different experiments provides a comprehensive and holistic approach to assess effects of oil sands materials arising from bank erosion-related processes, emphasising the need to discriminate natural processes from mining-related activities of surface and groundwater contamination in oil sands areas.

604

PCB fate and transport at the Lower Ottawa River (USA): A seven-year pre-/post-dredging analysis using sediment, passive samplers, aquatic invertebrates, and riparian spiders

R.R. Otter, Middle Tennessee State University / Biology; D. Walters, USGS / Columbia Environmental Research Center; J.M. Lazorchak, U.S. EPA / Office of Research and Development; K. Fritz, US EPA / Office of Research Development; M. Mills, U.S. EPA / National Risk Management Research Laboratory

In 2010, environmental dredging to remediate sediments contaminated with PCBs, PAHs, and lead was performed at select site locations in the Lower Ottawa River, a portion of the Maumee River Area of Concern (Ohio, USA), in 2010 to remediate. Prior to dredging, we designed a multi-metric study to assess contaminant fate and transport, ecosystem response, and recovery using a multiple lines of evidence approach. We measured PCB concentrations in surface sediment, passive samplers deployed in the water column, aquatic invertebrates, and spiders from 2009-2013 & 2015. Site-specific PCB concentrations were significantly and positively correlated among all metrics across all years except for sediment. Sediment concentrations at remediated and non-remediated sites were highly variable throughout the study period and were unreliable indicators of PCB concentrations in biota. PCB concentrations in aquatic invertebrates were highly correlated with concentrations measured in passive samplers, and in turn, were strongly predictive of concentrations in riparian spiders that are specialized predators of adult aquatic insects. All of these measures of PCB uptake, accumulation, and trophic transfer declined by 2015, indicating that the dredging remedy reduced PCB concentrations in biota to pre-remedy concentrations or below.

605

The role of bioturbation activity in species specific sensitivity of benthic invertebrates to contaminated sediments

N. Wieringa, University of Amsterdam/IBED Institute / FAME; B. Prast, A. Bakker, R. Melkert, University of Amsterdam; S. Droge, University of Amsterdam/IBED Institute / IBED; P. Verdonschot, University of Amsterdam IBED Institute; M. Kraak, University of Amsterdam / IBED-FAME

Benthic invertebrate bioturbation activity enhances resuspension of chemicals into the water column, thus exposing sediment dwelling organisms to harmful substances locked up in the sediment. Yet, benthic organisms differ in bioturbation activity, which may influence their sensitivity to contaminated sediments, as higher burrowing activities increase the rate at which sediment associated chemicals are released. Since experimental evidence is still lacking the aim of the present study was to quantify the influence of benthic invertebrate bioturbation activity on their sensitivity to contaminated sediments. To this purpose intact sediment cores were collected at locations identified as ‘chemical hot-spots’ and subjected to whole sediment bioassays with six benthic invertebrates differing in bioturbation rate: the non-biting midge *Chironomus riparius* (low), the worm *Limnodrillus hoffmeisteri* (low), the amphipod *Gammarus pulex* (intermediate), the isopod *Asellus aquaticus* (high), the mayfly *Ephemera danica* and the caddisfly *Sericostoma personatum* (both with unknown bioturbation activity). The bioturbation activity of the selected benthic invertebrates was determined by measuring turbidity of the overlaying water. The three test species for which the bioassays were succesful showed the lowest survival on the agricultural sediment, that also affected isopod growth most. Yet, exposure to the other sediments also caused reduced isopod growth Bioturbation activity of *G. pullex* was significantly higher than that of the other three invertebrates. *A.aquaticus* and *C. riparius* showed similar bioturbation activity. *L. hoffmeisteri* showed the lowest bioturbation activity. Employing these bioassays allowed ranking of contaminated sediments based on biological responses rather than on the absence of presence of compounds. The species specific responses to the most contaminated sediment could however not be related to their bioturbation activity. When comparing the survival of the different test species, the insects *C.*

riparius and *S. personatum* suffered from higher mortality than the crustacean. Hence, the contamination of the agricultural location affected the insects most, due to presence of the insecticide chlorpyriphos in the sediment. It is concluded that the presence of compounds with a specific mode of action (insecticides) outweighs the influence of bioturbation activity on species specific responses to contaminated sediments.

606
Paleoecotoxicology: Assessing the Toxicity of Lake Sediments Impacted by Legacy Gold Mining in Yellowknife, NT, Canada
C. Cheney, University of Ottawa / Biology; M.P. Pothier, University of Ottawa / Department of Biology; A.J. Poulain, University of Ottawa / Biology; J.B. Korosi, York University / Department of Geography; L.E. Kimpe, J.M. Blais, University of Ottawa / Department of Biology
Natural resource extraction has supported the development of Canada's far north, but has also resulted in environmental contamination at some operations. Such is the case in Yellowknife Northwest Territories, where two now abandoned gold mines operated throughout the latter half of the 20th century 5km north of the city. Due to ore processing techniques, approximately 20000 tonnes of particulate arsenic trioxide was deposited onto the landscape surrounding the mine. Consequently, elevated surface water arsenic concentrations have been reported in lakes within 17km of the mine at present. Here we develop methods in paleoecotoxicology to characterize the full extent of historic metal(loid) contamination and assess the toxicity of these historic sediments. We examine the potential of analysing sediment archives with an ecotoxicological perspective to reconstruct missing biomonitoring data at historically contaminated sites. This study examines lake sediment cores from 21 lakes within 30km of the Yellowknife. Sediments were dated using radiometric dating techniques, and the toxicity of dated sediment horizons was determined using the novel application of microbial bioreporters and modified *Daphnia* toxicity testing techniques. Metal(loid) profile concentrations track a peak in concentration during the height of mining operations, which decreases with distance from the city. Initial assessments of bioavailability and acute *Daphnia* toxicity indicate that arsenic in porewater is 50-90% bioavailable, while sediments deposited during the time of mining operations decrease *Daphnia* survivorship. These results indicate that lake sediment archives can be used to reconstruct missing biomonitoring data in sites of legacy anthropogenic influence. Additionally, these results highlight the importance of applying techniques in paleoecotoxicology in cases of legacy contamination, and suggest that aquatic ecosystems continue to show lingering contamination from past gold mining activities.

Bridging the Gap: Maximizing the Role of Mechanistic Approaches (Including Omics) for Better Chemical Safety Decisions Across Humans and Ecosystems (II)

607
Using transcriptomics to explain differential sensitivity to pesticide exposure: towards using omics to predict toxicology
S.J. Short, Cardiff University / School of Biosciences; A. Robinson, Centre for Ecology & Hydrology; E. Lahive, Centre for Ecology & Hydrology (NERC); D. Spurgeon, Centre for Ecology & Hydrology; P. Kille, Cardiff University
An *in silico* tool comparing omics to 'flag' sensitive species would improve risk assessment for untested species. To achieve this, we need to know how toxicokinetics (TKs) and toxicodynamics (TDs) contribute to differential species sensitivity (DSS). Therefore, we investigated the TKs and TDs underlying toxicity in earthworms exposed to the pesticides chlorpyrifos and imidacloprid, that both inhibit neuronal synaptic function by targeting Acetylcholinesterases (AChEs) and Nicotinic Acetylcholine receptors (nACHRs) respectively. Our analyses support the hypotheses that TDs drive the ~300x lower sensitivity of earthworms, relative to hexapods, to chlorpyrifos. For example, we find that a relatively moderate Cholinesterase (ChE) activity in the gut is the result of highly expressed but 'low-activity' ChEs. The inhibition of these ChEs by chlorpyrifos suggest earthworms have an underappreciated chlorpyrifos 'sink' that is unavailable to most hexapods, that generally possess only two neuronal ChEs. Earthworms are also ~100x less sensitive to imidacloprid than hexapods and, within earthworms, the Megascolecid, *Amynthas gracilis,* is ~30x more sensitive than Lumbricids, a difference that our comparisons suggest cannot be accounted for by differential TKs. The major TD target for imidacloprid is the synaptic nACHR-ion channels. In addition to nAChRs, the transcriptomics reveal that, unlike most hexapods, earthworms express high levels of Acetylcholine Binding Proteins (AChBPs), which are predicted to bind imidacloprid but lack an ion channel. Expression patterns suggest AChBPs have a nervous system function but previous analyses indicate they do not have a synaptic role. We hypothesise that AChBPs possess a moderately less critical (non-synaptic) function and act as a protective 'sink' preventing imidacloprid reaching the synapse. Furthermore, unlike the sensitive *A. gracilis*,the Lumbricids deploy a considerable portion of their AChBPs to non-neural tissues, perhaps offering greater protection of the neuronal functions mediated by the nAChR/AChBP targets. In summary, if the functions of nACHRs are more critical than neuronal-AChBPs, which are, in turn, greater than non-neuronal AChBPs, the expression of imidacloprid targets can arguably account for the observed DSS. Combined, these analyses suggest transcriptomics can aid the characterisation of TD drivers of DSS for pesticides and adds weight to the possibly of using omics to 'flag' sensitive species.

Linking molecular response and DEB modelling approaches
P. Antczak, University of Liverpool / Institute of Integrative Biology; L.M. Stevenson, Bowling Green State University / Ecology, Evolution and Marine biology; N. Vinas, U.S. Army Corps of Engineers / Engineer Research and Development Center; R.M. Nisbet, University of California, Santa Barbara
A working group at the National Institute for Mathematical and Biological Synthesis (NIMBioS) explored the feasibility of integrating 2 complementary approaches relevant to ecological risk assessment. Adverse outcome pathway (AOP) models provide "bottom-up" mechanisms to predict specific toxicological effects that could affect an individual's ability to grow, reproduce, and/or survive from a molecular initiating event. Dynamic energy budget (DEB) models offer a "top-down" approach that reverse engineers stressor effects on growth, reproduction, and/or survival into modular characterizations related to the acquisition and processing of energy resources. Thus, AOP models quantify linkages between measurable molecular, cellular, or organ-level events, but they do not offer an explicit route to integratively characterize stressor effects at higher levels of organization. While DEB models provide the inherent basis to link effects on individuals to those at the population and ecosystem levels, their use of abstract variables obscures mechanistic connections to suborganismal biology. To take advantage of both approaches, we developed a conceptual model to link DEB and AOP models by interpreting AOP key events as measures of damage-inducing processes affecting DEB variables and rates. To establish whether our approach has merit we developed a comprehensive molecular dataset based on *Chlamydomonas reinhardii*. Specifically, we generated metabolomics and lipidomics data as a result of exposure to 4 concentrations of Copper over 7 time points (0-145h). The design of the experiment was guided by principles required in both DEB modelling and OMICs data analysis. We analyse the molecular data using computational approaches to establish potential AOPs and ask the question whether the genes involved could further inform the DEB modelling procedures.

Pharmacology-informed prediction of the environmental risk posed by mixtures of non-steroidal anti-inflammatory drugs (NSAIDs) to fish
P. Marmon, Brunel University London / College of Life Sciences; S. Owen, AstraZeneca / Safety Health Environment; L. Margiotta-Casaluci, Brunel University London / Institute of Environment, Health and Societies
The presence of low concentrations of non-steroidal anti-inflammatory drugs (NSAIDs) in the aquatic environment has raised the concern that chronic exposure to these compounds may cause adverse effects in wild fish populations. This potential scenario has led to the inclusion of diclofenac in the European Union Watch List of emerging pollutants; however, there are currently over 30 NSAIDs on the market raising questions of mixture effects. Here we present an integrated pharmacology-informed framework that enables the prediction of potential adverse effects in fish exposed to a mixture of NSAIDs. This framework combines two mechanistic visions: network-centred and target-centred. Initially we generated an *in vitro* bioactivity network for a mixture of nine NSAIDs. This network, including over 140 nodes, was filtered using drug uptake and pharmacokinetic parameters to generate a more simple network displaying the biological activity expected at environmentally relevant levels of exposure. This was subsequently used to generate multi-organ target-phenotype anchoring predictions, specific for zebrafish, to identify the most likely phenotypic effects that might occur under the considered exposure scenario. This network-based approach was successively combined with a more traditional target-centred approach based on the pharmacological hypothesis that the sustained inhibition of NSAIDs primary targets - cyclooxygenase (COX) 1 and 2 – in healthy tissues is the key driver of toxicity. We developed a quantitative Adverse Outcome Pathway-informed model that incorporates both pharmacokinetic and pharmacodynamic aspects of NSAIDs toxicology. This dynamic visual model enables a rapid assessment of the risk posed by environmental levels of NSAIDs, and their potential to trigger multi-scale adverse effects. Although total COX inhibition activity in the plasma of wild fish may be sufficient to trigger COX IC50s, the mean effect concentrations for all 10 phenotypic endpoints are above predicted environmental levels. Only 9% of the effect concentration data points were within predicted environmental levels, residing within endpoints for reproduction, immunomodulation, male testosterone, and plasma prostaglandin. We anticipate that the integration of these mechanistic approaches will provide a useful predictive tool to support the implementation of effective NSAIDs ecopharmacovigilance strategies; facilitating the regulatory interpretation of past and future toxicity data.

SKIPS: Stochastic Knowledge-based Interaction Pathway Simulator
M. Rowland, U.S. Engineer Research and Development Center / Ecological Fate

and Effects Division; N. Reyero, US ACE Engineer Reserach and Development Center / Environmental Laboratory; E.J. Perkins, M.L. Mayo, US Army Engineer Research and Development Center / Environmental Laboratory

The field of toxicology suffers from a lack of predictive models and mathematical frameworks that link molecular processes to whole organism responses. A major problem is that measurements made from molecular level assays are inherently noisy, and such variance injects doubt into organism level outcomes linked to them. Even worse, whole organism measurements are often reported using low numbers of replicates, which may be sufficient to test for an effect (toxic/non-toxic), but are variable enough that deterministic models built from these data suffer from only marginal predictive fidelity. Given that experimental data is often quite variable, predictive models should aim to incorporate noise and uncertainty—not ignore it. Here we describe such an approach, termed the Stochastic Knowledge-based Interaction Pathway Simulator (SKIPS), which thrives on datasets that exhibit a broad range of measurement variation in both the inputs (e.g., molecular exposure assays) and endpoint measurements that span increasing levels of biological organization. Existing approaches to modeling noisy datasets shoehorn variation into deterministic models by adding a "noise term" (e.g., stochastic differential equations), but this method requires users to make broad, ad hoc simplifying assumptions regarding the type of noise (e.g., white or colored noise), and may therefore not effectively capture the statistics of the experimental data with low enough error to establish confident predictions of toxic effects. In contrast, SKIPS shortcuts a formal stochastic simulation by modeling the mean response at each biological level around which conditional Monte Carlo sampling is used to generate variation statistically consistent with training data. A conditional probability distribution associated with a biological response can thus be reconstructed using this method for certain input values. We demonstrate the utility of SKIPS via a reproduction-related adverse outcome pathway in the adult female fathead minnow (*Pimephales promelas*). SKIPS correctly captured the NOEC, LOEC, and point of departure (POD) measurements impacting average fecundity for chronic trenbolone bexposures. This success highlights the potential for SKIPS to support rapid screening efforts in toxicology or to enable decision making in applications where predicting chemical risks and hazards is important.

Vision of a near future: bridging the Human Health - Environment divide. Toward an integrated strategy to understand mechanisms across species for chemical safety assessment

C. Rivetti, Unilever / Safety and Environmental Assurance Centre SEAC; G. Hodges, Unilever Research / Safety and Environmental Assurance Centre; E. Butler, Unilever RD Colworth / Safety and Environmental Assurance Centre SEAC; C. Rendal, S. Scott, Unilever / Safety and Environmental Assurance Centre SEAC; B. Campos, Unilever R&D / Safety and Environmental Assurance Centre SEAC

There is a growing recognition that mechanistic approaches to understanding cross species target and pathway homology provide significant opportunities in risk assessment (RA) for both Human Health (HH) and environmental safety. Specifically, it has been recognized that a more comprehensive and reliable understanding of pathways will better enable the extrapolation of potential adverse impacts across species. Ultimately, this would allow a mutual exploitation for HH and Ecotoxicological RA to coherently and more efficiently characterize overall hazard. Given the broad inter-species differences occurring at multiple levels of biological organization, there is unlikely to be a "one-size-fits-all" solution that can effectively characterize species similarities / dissimilarities completely. However, there are some pragmatic first steps that can be taken using emerging and developing technologies (including high-throughput molecular techniques). Thus, there is a need for new approaches to identify, characterise and (ideally) quantify those differences and how mechanisms of action may differ across species. Motivated by these questions, Unilever sponsored a workshop to discuss how we can make better use of existing data and how to efficiently generate new data to derive mechanistic understanding between humans and environmentally relevant species and ultimately aim at more efficient, holistic (HH and Environment) chemical safety decisions. Experts from tripartite stakeholders (industry, academia and governmental agencies encompassing both human health and environment) were brought together to discuss this concept. This workshop highlights a common will to progress ever more to mechanistically-based data driven animal-free chemical safety assessments. The discussion addressed current gaps and key challenges, proposed solutions and identified research priorities for the future. Overall, the participants recognize that there is no silver bullet and no single fit-for-all approach which would provide us with all answers, but also acknowledged we have now the incentive, tools and information available to start developing this concept, maximizing the advantages of the different data sources to improve confidence and efficiency of RA.

612

A framework to demonstrate the applicability of omics in human health and environmental risk assessments

E. Butler, Unilever RD Colworth / Safety and Environmental Assurance Centre SEAC; G. Hodges, Unilever Research / Safety and Environmental Assurance Centre; S. Gutsell, Unilever / SEAC; I. Muller, Unilever; B. Campos, Unilever R&D / Safety and Environmental Assurance Centre SEAC; C. Rivetti, Unilever; A. White, Unilever / Safety and Environmental Assurance Centre SEAC; M.R. Viant, J. Colbourne, University of Birmingham / School of Biosciences

In recent years there has been a paradigm shift towards gaining more mechanistic toxicological insights in risk assessments. The drivers for this shift are a desire to move away from the animal testing requirements of conventional risk assessment as well as to move towards more transparent/scientifically valid approaches to toxicology [1]. Whilst advances in technology have resulted in an explosion of omics data being generated across multiple species, there is little evidence of it being used in chemical risk assessment or for making risk based decisions. One of the main perceived weaknesses of making decisions from genomics data is the lack of standardised approaches for method development, data analysis, data interpretation and validation. The approaches are also criticised as the observed effects are often not linked to a measurable apical endpoint in the species of interest or that an adverse effect is observed in a cell model without being able to see if those effects are likely to cascade down to organism effects. The use of omics data offers multiple potential benefits. Firstly, by looking at fingerprints of molecular perturbations following exposure to a toxicant, hazard identification can become possible by establishing a mechanism of action (MechoA). By looking at patterns of responses to compounds in well standardised systems, read-across may become possible. In addition, as we learn more about omics responses to different MechoAs, we will be able to design new and relevant biomarkers in the future for screening new chemicals. There is an understanding that we cannot test every ingredient on every organism, therefore, one of the greatest advantages to the use of omics data is that it allows us to look across species to identify areas of commonality or concern across human health and environmental risk assessment and to maximise opportunities for inferring mechanisms from one species/ test results to another. The aims of this work are to demonstrate that although we might not be ready to perform human health or environmental risk assessments based solely on genomics data, we can start including it alongside conventional data. This can be used as part of a WoE approach to gain better mechanistic insight. Here we present a proposed framework to demonstrate how new mechanistically derived data can be used to complement our current approaches to deliver a robust risk assessment applicable across both human health and the environment.

New Frontiers in Life Cycle Inventory Data Collection and Modelling (II)

Methodology for the development of a hybrid regional supply and use model for the three Belgian regions

E.B. Towa, Université Libre de Bruxelles / Recycling and Environment; V. Zeller, Université Libre de Bruxelles; J. Schmidt, S. Merciai, 2.-0 LCA consultants; W. Achten, Université Libre de Bruxelles / Geoscience, Environment and Society

Recently, environmental-extended multi-regional-input-output (EEMRIO) datasets have been developed enhancing the possibilities to assess environmental impacts of products, sectors and regions with economy-wide scope. However, compared to these developments, subnational EEMRIO datasets and applications develop at slower pace although the political demand for regional assessment is high. This assessment at regional level requires reliable and complete regional data inventories. However, there are still practical barriers to build such inventories, e.g. the access to and the compatibility of regional data are often restricted and the collection of new data is time-consuming. With this research, we want to demonstrate how such an inventory can be developed at regional level and propose a methodology to build regional hybrid supply and use tables (HSUTs). This model can perform material flow analysis and environmental impacts assessments in order to support resource management strategies. In this study we focus on the following methodological developments: increasing the spatial resolution, improving the product and sectors detail as well as measuring the products flows in physical units rather than monetary units. These developments of the inventory will be achieved through a combination of existing datasets. The available datasets for Belgium include: the national monetary and hybrid supply and use tables of EXIOBASE, the regional monetary SUTs (MSUTs) and available auxiliary data obtained from regional statistics such as: physical data on production and waste treatment data. We regionalize the Belgian HSUTs of EXIOBASE using the regional MSUTs and the auxiliary data at regional level.The regional hybrid model is the first attempt, to our knowledge of regionalizing EXIOBASE. If regional data are available, the developed methodology is applicable for another country covered in EXIOBASE and when regional data are available. The major shortcoming of the model is that by far not all needed data was readily available in physical units. To overcome the limitation, first estimations were made, which were then improved with a balancing procedure. But even though the model is data dependent, it is a flexible tool that offers the possibility to be updated when new data becomes available. <br clear="all" /> [1] "region" in MRIO refers to a country or a group of country. [2] Hybrid refers to the mixed-unit framework including: mass and energy (products) and monetary (services).

614
Introducing the trade "supply mix" to improve regionalisation of Life Cycle Inventory for agricultural commodities
M.J. Lathuilliere, Stockholm Environment Institute / IRES; J. Godar, P. Löfgren, Stockholm Environment Institute; B. Ayre, Global Canopy; T. Gardner, C. Suavet, Stockholm Environment Institute
One important challenge towards further regionalisation of life cycle assessments (LCAs) is to provide life cycle inventory (LCI) flows at a fine enough spatial resolution to reduce uncertainty of potential impacts. This challenge is particularly important for agri-food products given spatial variability in production. Here, we introduce the trade "supply mix" as the ensemble of elementary flows of an agricultural commodity for a given supply chain, which we apply to provide biome specific land occupation and transformation LCI for one tonne of Brazilian soy produced in 2017. We use the Transparency for Sustainable Economies information platform (Trase) which combines customs declarations, tax and shipping information to link municipality-level soy production to importing countries. This information is then connected to Brazilian biome boundaries and deforestation data to obtain biome specific land occupation and transformation elementary flows for soy destined to China, France, Germany and Finland. Results show different biome sources for soy imported into France and China compared to Germany and Finland. China and France showed greater land occupation in the Amazon with land transformation occurring in Amazon and Cerrado biomes. Germany and Finland's imported soy had a land occupation LCI with a greater proportion of Atlantic Forest compared to other biomes, with Finland, however, showing no land transformation LCI associated with soy. After calculating the biodiversity damage associated with soy exports, we noted that Finland had the largest land occupation damage, followed by China, France and Germany, while both China and France had similar land transformation biodiversity scores. Given the nature of the trade data and their spatial resolution, the trade supply mix could be used to calculate other elementary flows for agri-food products (e.g., water use, greenhouse gas emissions, fertilizer application) and can also be related to companies and organizations such as producers and traders. These elementary flows will be derived and made available through the Trase platform.

615
Significance of pesticide emission modelling for assessing ecotoxicity impacts of agricultural systems
N.A. Peña, IRTA / GIRO; M. Trydeman Knudesen, Aarhus University AU / Department of Agroecology; P. Fantke, Technical University of Denmark / Quantitative Sustainability Assessment Division; A. Assumpcio, IRTA / GIRO-Integral Organic Waste Management Program; J. Hermansen, Aarhus University AU / Department of Agroecology
With the increased global demand for agricultural products and the interrelated concerns on the environmental impacts, there is a need to have efficient tools to evaluate the environmental performance profiles of agricultural systems, to facilitate a move towards more sustainable production. Life Cycle Assessment (LCA) is widely applied to quantify potential impacts of products and systems along with their entire life cycles. One of the main challenges in assessing the environmental performance of agricultural systems in LCA is modelling emissions from pesticide use. Hence, this study aims to evaluate the effect of modelling choices to estimate pesticide emission fractions on the environmental impact profiles in a case study conducted on feed crops in Denmark (DK). This study followed the LCA methodology to evaluate the potential ecotoxicity impacts on freshwater ecosystems from pesticide use in DK's crop production. This analysis focuses on the evaluation and influence of pesticide application on the environmental impact profiles of maize, winter wheat, grass, spring barley, rapeseed and peas, testing the effects of the choice of the emission-modelling framework. Two types of local sensitivity tests were conducted, a scenario sensitivity analysis to test the effect of LCI modelling on the impact profile of the crops and a local sensitivity to input parameters for the reference scenario. Three different emission-modelling choices were tested; they differ on the underlining assumptions and data requirements. The median results for the resulting emission fractions vary by four orders of magnitude for the different models. Main aspects influencing impact results are the interface between inventory estimates and impact assessment, and the consideration of intermedia processes, such as crop growth development and pesticide application method. As showed neglecting such inter-media process, may entail overestimation of the emission fractions, and hence, application of the conservative default pesticide emission may lead to an overestimation of the potential toxicity impacts induced by application of pesticides in most agricultural LCA. Statistical differences were found in the impact results with two of emission model tested, thereby indicating the influence of modelling choices on ecotoxicity impact assessment. In conclusion, significant differences in emission estimates and related impacts were found between the scenarios for all crops.

616
Simple N direct field emissions for agricultural LCA: towards a model adapted to contrasting climate and agricultural management
V. Galland, INRA / UMR SAS; A. Avadí, CIRAD / UPR Recyclage et risque; C. Bockstaller, INRA / UMR LAE
Estimating nitrogen losses (in all its different forms: NH_3, NOx, NO_3, N_2O) from field nitrogen management (fertilisation, soil cover, *etc.*) is one of the main challenges in agricultural LCA. N losses are a major contributor to several LCA impact categories (*e.g.* climate change, eutrophication). LCA practitioners typically use the most accessible models, in terms of data demand and ease of use, such as emission factors or pre-defined model sets associated with databases. However, these models are predominantly representative of field crop conventional fertilisation by synthetic fertilisers. They are not well adapted to contrasting climates (from temperate, dry to tropical conditions) or contrasting agricultural systems (vegetable gardening, intercropping, perennials). Furthermore, they are not (or very little) sensitive to farming practices and cannot assess the effect of "eco-designed" farming systems or the particularity of organic fertilisers. After a review of the different N field emissions models used in LCA, we identified the potential of the INDIGO-N model for improving N emissions assessment in agricultural LCA. Without being a complex soil-plant dynamic model, INDIGO-N addresses effects of climatic and soil conditions, fertilisation in regard with the plant's needs, or some management practices. The goal of this work is to improve the INDIGO-N model to create a reference model for N losses in agricultural LCA. The objectives are multiple: ? improve the organic fertilisation assessment (with calculation of the mineral fertilisation equivalent of each input) ? assess a wide range of crops with different cultivation durations (field crops, vegetables, associations, perennials) ? integrate each crop into its crop sequence ? adapt the assessment to different climates (temperate, tropical, sub-tropical, dry) ? take into account the plant's needs and a range of agricultural practices (e.g. mitigation strategies, over-fertilisation). While being more complex than most of the simple N models used in LCA, INDIGO-N aims at being adapted to LCA constraints of feasibility, allowing to estimate the N losses for both average productions (*e.g.* a national average wheat) and specific eco-designed agricultural systems. An excel tool will be provided to calculate the N losses and the model will be implemented into MEANS-InOut, an LCI-generator software for agricultural LCA developed by INRA and CIRAD.

Towards global LCI data on urban wastewater discharges
I. Munoz, 2.-0 LCA consultants
We present version 3 of WW LCI, a model to calculate LCIs of urban wastewater discharges in 69 countries. It covers wastewater treatment at primary level (settling tank), secondary (biological treatment), tertiary (N/P removal, filtration, disinfection) and septic tanks. Sludge disposal includes composting, landfilling, incineration and agricultural use. We have improved the model at two levels: **1) Wastewater components**: the model was designed to cover modelling of chemicals in wastewater, where the individual chemicals must be identified, as done in environmental risk assessment. In WW LCI v3 we adapt the model to also support generic descriptors: chemical oxygen demand (COD), suspended solids (SS), toal N and total P. Also, the presence and fate of heavy metals is now supported too. The model is now capable of a complete coverage of wastewater components: organic matter, nutrients, organic micropollutants and metals. **2) Country coverage**: The database in WW LCI v3 has been extended from 56 to 69 countries (83% of the world's population). New variables by which every country is now described includes: - Methane emissions from open sewers, adjusted for the country's climate. - Electricity consumption in the wastewater treatment plants (WWTPs) as a function of plant capacity. - Wastewater infrastructure (sewers and WWTPs) is quantified for each country using five capacity classes. - Extent of anaerobic digestion of sludge and cogeneration of heat and electricity with biogas is established for each country. - The heat balance at the WWTP is calculated taking into account the country's climate. - Sludge landfilling includes uncontrolled landfills. In each country we define a controlled/uncontrolled landfill mix. - Emissions of pollutants are specified as a combination of discharges to the sea, freshwater and groundwater. We present results for the 69 countries in the database, for discharging 1 m3 wastewater with (in mg/L): 500 COD, 250 SS, 30 N and 6 P. Greenhouse-gas emissions per m3 range from 0.3 kg CO2-eq in Japan to 1.7 kg CO2-eq in Bangladesh. Results can be calculated for any other impact category, using LCA software. This is to our knowledge the most complete LCI tool for urban wastewater. It is flexible, allowing the user to either rely on chemical-specific assessments, specific country conditions, or on generic measures (COD, N, P, SS) and average country conditions. We expect the country database will keep expanding to achieve a global coverage.

LCA of urban water systems: STOIC, a dynamic LCI model linking human activities and wet-weather pollutant discharges
E. Risch, IRSTEA Montpellier / UMR ITAP; P. Roux, ITAP Irstea Montpellier SupAgro Univ Montpellier / ITAP ELSA-PACT; E. Loiseau, ITAP Irstea Montpellier SupAgro Univ Montpellier; C. Sinfort, ITAP, Irstea, Montpellier SupAgro, Univ Montpellier / ELSA Research group and ELSA-PACT Industrial Chair
With unprecedented urban growth at the planetary scale, urban wastewater systems (UWS) are faced with the operational challenge of managing ever increasing and polluted stormwater to mitigate impairments of the quality of

aquatic ecosystems. However, to which extent do wet-weather control strategies actually help reduce overall environmental impacts? With the general aim of assessing in a whole-systems perspective to improve the environmental assessment of UWS with Life Cycle Assessment (LCA), by including impacts from operation and infrastructure, and impacts from treated pollutants in discharges, the objective of this work is to answer the question: "Is it possible to perform the LCA of Urban Wastewater Systems that captures the temporal variability of water discharges in an urban catchment?". This work describes a site-dependent framework to estimate for life cycle inventory (LCI) purposes, intermittent discharges (ID) from UWS with consideration for their important spatiotemporal variability at the urban catchment scale. The model (named STOIC, as an abbreviation for "STOrmwater Inventory Conceptualization") satisfies requirements on inventory data quality to support sufficiently accurate modelling of IDs and conceptualizes stormwater processes occurring within an urban catchment and its UWS. These stormwater processes include the generation of water pollutants from nonpoint source emissions to the routing and distribution of pollution in the UWS components, resulting in spatiotemporally differentiated LCIs for water pollutants within an urban catchment. The STOIC framework is applied to a UWS at sub-catchment scale to assess global performances of different control strategies for IDs in terms of environmental impacts in a real-world case study in Bordeaux, southwest France. This demonstrates the interest and applicability of an extended environmental assessment which considers the temporal variability of UWS discharges from an urban sub-catchment.

Incorporating Ecosystem Functioning into Environmental Quality Assessment

619
Linking ecotoxicological risks and ecosystem functioning
M. de Baat, University of Amsterdam / IBED-FAME; G. van der Lee, N. Wieringa, University of Amsterdam/IBED Institute / FAME; P. Verdonschot, Alterra, Wageningen-UR / Department of Freshwater and Marine Ecology; M. Kraak, University of Amsterdam / IBED-FAME
In response to environmental quality deterioration, policies, like the EU Water Framework Directive (WFD), have been adopted that aim at achieving a good chemical and ecological status of water bodies. According to the EU WFD, monitoring strategies should include the assessment of both ecosystem structure and functioning in the determination of the ecological status. However, in practice the monitoring of surface waters often only encompasses structural measurements related to physicochemical parameters and biological community composition, while ecosystem functioning, despite its relevance, is largely overlooked. Therefore, this study aimed to investigate the relationship between contamination driven ecotoxicological risks and ecosystem functioning in Dutch surface waters. To this end, measurements of toxic pressure and decomposition were conducted at 19 surface water locations with different pollution sources. Toxic pressure was assessed by employing a bioassay battery of *in situ*, *in vivo* and *in vitro* bioassays. Decomposition by microbes and invertebrates was measured *in situ*. The present abstract discusses the preliminary results of the bacterial inhibition bioassay and microbial decomposition rates, awaiting promising results of further analyses. Bacterial inhibition at WWTP sites, caused by polar compounds, coincided with elevated microbial decomposition rates at these locations. These results suggest that WWTP locations accommodate a highly adapted microbial community that is capable of organic matter decomposition at a rate exceeding that of all other investigated locations, despite the observed toxic pressure to bacteria. The here presented observations shed new light on the role of ecosystem functional parameters such as decomposition in the determination of surface water quality. Functional parameters can be included in surface water quality monitoring, but a better understanding and rationale behind the attribution of certain water quality scores based on functional parameters, and their relationship to observed toxic pressure is still lacking. It is concluded that only by combining environmental chemistry (compound concentrations), toxicology (adverse effects of environmental samples) and ecology (ecosystem functioning), an integrated cause-effect oriented water quality assessment can be achieved.

620
Meta-analysis of glyphosate contamination in surface waters and dissipation by biofilms
L. Carles, H. Gardon, L. Joseph, Université Blaise Pascal; J. Sanchis, IDAEA-CSIC / Environmental Chemistry; M. Farre, IDAEA- CSIC; J. Artigas, Université Blaise Pascal
One consequence of the intensive use of glyphosate is the contamination of rivers by the active substance and its metabolites aminomethyl phosphonic acid (AMPA) and sarcosine, inducing river eutrophication. Biofilms are the predominant lifestyle for microorganisms in rivers, providing pivotal roles in ecosystem functioning and pollutant removal. The persistence of glyphosate in these ecosystems is suspected to be mostly influenced by microbial biodegradation processes. The present study aimed to investigate the tripartite relationship among biofilms, phosphorus and glyphosate in rivers. The first part consists of a co-occurrence analysis among glyphosate, AMPA and phosphorus using an extensive dataset of measurements (n = 56198) from French surface waters between 2013 and 2017. The second part investigated the capacity of natural river biofilms to dissipate glyphosate, depending on phosphorus availability and the exposure history of the biofilm, in a microcosm study. A strong co-occurrence among glyphosate, AMPA and phosphorus was found in surface waters. More than two-thirds of samples contained phosphorous with glyphosate, AMPA or both compounds. Seasonal fluctuations in glyphosate, AMPA and phosphorus concentrations were correlated, peaking in spring/summer shortly after pesticide spreading. Laboratory experiments revealed that natural river biofilms can degrade glyphosate. However, phosphorus availability negatively influenced the biodegradation of glyphosate and induced the accumulation of AMPA in water. An increase in alkaline phosphatase activity and phosphorus uptake was observed in glyphosate-degrading biofilms, evidencing the tight link between phosphorus limitation and glyphosate degradation by biofilms. The results of the present study show that phosphorus not only is a key driver of river eutrophication but also can reduce complete glyphosate degradation by biofilms and favour the accumulation of AMPA in river water. The predominant role of biofilms and the trophic status of rivers must therefore be considered in order to better assess the fate and persistence of glyphosate.

621
Using stable isotopes (δ13C and δ15N) together with functional microbial, plant and soil parameters to uncover effects on soil nutrient cycling in polluted fields
I. Rijk, MTM Research Centre, Orebro University / Ecosystem Ecology; A. Ekblad, MTM Research centre Örebro University / Ecosystem Ecology; D. Berggren Kleja, Swedish University of Agricultural Sciences
The microbial degradation and transformation of complex organic material (e.g. litter, dead plants) towards smaller inorganic compounds and nutrients that can be taken up by plants, is a crucial soil process that determines soil fertility and productivity of terrestrial ecosystems. Effects of pollutants on microbial functioning have been mostly studied under controlled (lab) or semi-controlled field conditions, but there is a need for more field studies and non-disruptive ways to study microbial functioning. Since there is not one golden parameter to study microbial nutrient cycling, we applied a combined approach using different functional microbial, soil and plant parameters together with stable isotope techniques. The measurement of microbial soil respiration (CO_2 released with the breakdown of organic compounds) is the most direct way to assess effects on microbial activity. To enable a field study, we add cane sugar (naturally isotopic labelled) to bypass root interference and stimulate microbial activity. In addition, shifts in C and N content and the natural isotopic abundance of ^{13}C and ^{15}N in plant, soil and microbial biomass provide a more time-integrated view on the nutrient cycling function and are not influenced by short-time fluctuations. So far we studied a lead (Pb) polluted shooting range, a copper (Cu) polluted wood impregnation site, and a lysimeter experiment. The results of the first field study suggested that our methods are useful in evaluation of nutrient cycling in field studies of polluted sites. A decreased microbial decomposition in high Pb polluted plots was suggested by a lower substrate-induced respiration of the cane sugar. Furthermore, from the combined results of soil, plant and microbial biomass C, $\delta^{13}C$, N and $\delta^{15}N$, we drafted conclusions about disturbance of N cycling as well as nutrient- and/or water stress to plants. Results from other sites are currently under evaluation and will be used as a comparison and to confirm usefulness of the methods. This approach remains challenging, because it is dependent on a suitable low or non-polluted reference soil in the same area. Furthermore, a discussion should be held on the definition of disturbance of nutrient cycling, e.g. which parameters, direction and rate of change. We show that a combination of functional microbial, plant and soil parameters, and the aid of stable isotope techniques, may help to detect changes in ecosystem functions in polluted sites.

622
A trait driver ecological theory predicts complex responses of phytoplankton exposed to chemical stress
L. Nizzetto, Norwegian Institute for Water Research NIVA; D. Baho, NIVA Norwegian Institute for Water Research; J. Norberg, Stockholm Resilience Centre; D.O. Hessen, University of Oslo / Department of Biosciences; F. Pomati, Eawag Swiss Federal Institute of Aquatic Science and Technology / Aquatic Ecology; J. Moe, Norwegian Institute for Water Research NIVA / Section for Ecotoxicology and Risk Assessment; B. Skjelbred, NIVA Norwegian Institute of Water Research; E. Leu, Akvaplan-niva
Understanding the processes shaping the structures and functioning of ecosystem is key to assess their vulnerability and predict their development under stress. The trait-driver theory (TDT) was recently introduced to describe the relationship between organisms' characteristics (traits), their assembling in communities and the emerging ecological functions. In so, it mechanistically details the processes underpinning response capacity (RC), the efficiency of a system in maintaining functionality by changing structures when conditions change. Despite being a fundamental concept in resilience theory, no direct measurements of RC has been drawn from empirical observations, so far. Furthermore, a detailed experimental assessment of TDT predictions is missing too. We run in situ experiments with two distinct lake phytoplankton communities stressed for the first time with a

mixture of micropollutants at environmentally realistic concentrations. We drew TDT expectations on community responses using an individual-base model. We compared formally elaborated theoretical expectations with the results of the experiment and found that TDT successfully predicts changes in size distribution, functional group turn-over and functional responses of the two communities. We also provide empirical evidence and a measure of their RC by looking at the rate of change of phytoplankton traits and its correlation with production. An empirical assessment of ecosystem RC is presented here for the first time. RC emerges as a trait-based measure of community responses linked to the maintenance of ecological functions under environmental changes.

623
Freshwater phytoplankton community response across different historical contamination backgrounds
S. Rizzuto, Lancaster University / Lancaster Environment Centre; D. Baho, NIVA Norwegian Institute for Water Research; L. Nizzetto, Norwegian Institute for Water Research NIVA; K.C. Jones, Lancaster University / Lancaster Environment Centre; F. Pomati, Eawag Swiss Federal Institute of Aquatic Science and Technology / Aquatic Ecology; J. Norberg, Stockholm Resilience Centre; D.O. Hessen, University of Oslo; E. Leu, Akvaplan-niva
Long-term recurrent exposure caused by the herbicide runoff from fields can impose a strong selective pressure on natural freshwater phytoplankton communities, favoring more tolerant species (pollution induced community tolerance - PICT). Adaptation to pollutants occurs through physiological and evolutionary changes. However, acquiring tolerance may have a trade-off where the most tolerant species might not be the most productive. The aim of this study is to differentiate between the imprint of long-term adaptation vs. short-term acclimation of natural phytoplankton communities originating from different historical contamination backgrounds. We conducted a 2-phase controlled experiment with phytoplankton communities grown from sediment containing seed banks (biological archives) from 2 lakes: a near-pristine forested (Finnsjön) and an Isoproturon historically exposed agricultural catchment (Tåkern), in Sweden. In phase 1, phytoplankton communities from the 2 lakes were germinated for 2 weeks in presence and absence of a sub-lethal level of Isoproturon (12 μg/L). During phase 2, we exposed the germinated communities for a week to 4 Isoproturon concentrations (7, 12, 61, 92 μg/L) following total biovolume development, photosynthetic efficiency (maximum quantum yield of photosystem II, F_v/F_m), and community composition. Lakes differed in biomass development, photosynthetic efficiency and community composition. Tåkern showed higher biovolume in phases 1 and 2. However, in phase 2, when exposed to the highest herbicide levels, Tåkern biomass dropped significantly compared to Finnsjön. Shannon diversity index evidenced the presence of tolerant species in Tåkern, favoured at higher exposure levels. Generally, Tåkern had a better photosynthetic efficiency recovery than Finnsjön. In particular, in Finnsjön the presence of herbicide during germination had a detrimental effect on the recovery of photosynthetic yield at higher exposure levels, whereas beneficial effects were observed in Tåkern. Long-term adaptation favours species with better tolerance to chemical disturbance at the expense of the most productive one. Short-term acclimation had a positive noticeable effect only on the recovery of photosynthetic efficiency and were dependent of previous long-term exposure. The pristine lake showed no sign of acclimation but more efficiency in sustaining biomass production even at high exposure levels.

624
Novel experimental approaches to study complex phytoplankton community responses to contaminant exposure
E. Leu, Akvaplan-niva; D. Baho, NIVA Norwegian Institute for Water Research; S. Rizzuto, Lancaster University / Lancaster Environment Centre; P. Færøvig, University of Oslo; F. Pomati, Eawag Swiss Federal Institute of Aquatic Science and Technology / Aquatic Ecology; J. Norberg, Stockholm Resilience Centre; L. Nizzetto, Norwegian Institute for Water Research NIVA
Diffuse contamination by chemical compounds is a wide-spread phenomenon in freshwater ecosystems in densely populated areas. Little is known about the effects of chronic exposure on ecosystem structure and functioning. The complexity of natural systems prevents straightforward inferences from standard test results towards community level changes, in particular ecological processes and functions. During a 4yr research project on *Pollution and ecosystem adaptation to changes in the environment*, we developed and deployed successfully setups to study complex phytoplankton community responses. The first experiment mimicked chronic background exposure to different levels of 12 common PPCPs (pharmaceuticals and personal care products). Phytoplankton was collected from lakes, transferred to dialysis bags, spiked with PPCPs, and incubated *in situ* at the depth of maximum chlorophyll a concentration for three weeks. The development of the communities was documented every 4th day with respect to different structural and functional measures. Phytoplankton was growing well within the bags. The variation across replicates was low and allowed tracking the effects of PPCPs on communities' structures and performances reliably. A second experiment addressed the role of adaptation vs. acclimation in a phytoplankton response towards herbicide exposure. To this end, natural communities were germinated from sediments of two lakes with contrasting historic contamination, in the presence and absence of isoproturon. The resulting communities were then exposed to different isoproturon levels. Measured endpoints included growth rates, photosynthetic efficiency, biovolume accumulation, species composition and biodiversity. Phase I of this experiment yielded divers algal communities, with species compositions being distinct for each lake. Phytoplankton communities originating from the agricultural catchment lake performed better when being exposed to acutely toxic concentrations of isoproturon, compared to those originating from the forested catchment – irrespective of their germination conditions in the laboratory. For moving ecotoxicology more towards stress ecology it is essential to develop approaches that allow to test natural communities' responses under realistic scenarios and on relevant time scales. This is the only way to reveal the ecologically relevant long-term impact of contaminants in the environment, including its interference with biological processes and functions.

New Developments in the Science of vPvB and PBT Assessment (II)

625
Bioconcentration of cationic surfactants in fish
M. McLachlan, Stockholm University / Environmental Science and Analytical Chemistry (ACES); A. Kierkegaard, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; M. Strandell, Stockholm University; B. Yuan, Stockholm University / Department of Environmental Science and Analytical Chemistry (ACES); J.M. Armitage, AES Armitage Environmental Sciences, Inc / Physical and Environmental Sciences; J.A. Arnot, ARC Arnot Research & Consulting / Adjunct Professor, Department of Physical & Environmental Science/Department of Pharmacology and Toxicology; S. Droge, University of Amsterdam/IBED Institute / IBED
The bioconcentration of a series of methyl alkyl amines was studied in rainbow trout. The test chemicals included primary, secondary, tertiary and quaternary amines ranging in chain length from C9 to C16. In an initial set of experiments we explored the tissue distribution of the test chemicals in ?130 g rainbow trout. After 7 d of exposure to mixtures of the alkyl amines the fish were sacrificed, and samples of muscle, liver, gill, skin and skin mucus were taken for analysis. All of the alkyl amines except for the two quaternary amines were quantified in all of the 5 tissues, and it was concluded that all of these tissues must be included when assessing the bioconcentration of alkyl amines. In a second set of experiments we measured uptake and depuration of mixtures alkyl amines in ?11 g rainbow trout and determined bioconcentration factors (BCFs). The experiments were conducted at 2 different pHs (7.8 and 6.3), with an exposure phase of 14 d and a depuration phase of 28 d. The concentrations of the test chemicals in water were relatively constant during the exposure experiment, with relative standard deviations ranging from 2-9%. This shows that it is possible to overcome the experimental challenges to conducting BCF studies for these strongly sorbing chemicals. Extracts of whole fish homogenates are currently being analysed for the determination of the BCFs. The influence of the structure of the alkyl amines and the pH on the BCF will be presented and discussed.

626
The Problem with Growth Correcting the BCF and BMF in Bioaccumulation Assessments & Possible Solutions
F. Gobas, Simon Fraser University / Resource & Environmental Management; Y. Lee, Simon Fraser Univeristy / Resource and Environmental Management
The OECD 305 guidelines for conducting aqueous and dietary bioaccumulation tests include the determination of a growth-corrected bioconcentration factor and biomagnification factor. While a growth correction appears appropriate for assessing bioaccumulation in very slowly growing fish species, the method by which the growth correction is performed violates (i) the mass-balance assumption, on which the bioaccumulation model is based; and (ii) the bioenergetics model, which, although not specifically recognized in the bioaccumulation model, underlies a correct description of the bioaccumulation process. Violating the mass balance assumption produces implausible bioconcentration and biomagnification factors that poorly represent the biomagnification behaviour of a chemical in nature. In addition, the OECD 305 guidelines regarding growth correction do not correctly account for the error in the BCF and BMF values caused by the growth correction. This error affects the comparison of measured BCFs and BMFs to regulatory criteria. In this presentation, we (i) illustrate the theoretical rationale for why the growth correction of the BCF and BMF is incorrect; (ii) present the error in the BCF and BMF values as a result of incorrect growth correction for a range of chemicals; (iii) present methods for conducting growth corrections that respect mass balance and energy balance; and (iv) discuss the relevance of growth correction on the classification of chemicals as Bioaccumulative (B) or Very Bioaccumulative (vB) substances.

627
Conduction of a freshwater trophic magnification study based on a comprehensive literature evaluation

V. Kosfeld, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; H. Ruedel, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Department of Environmental Monitoring; C. Schlechtriem, Fraunhofer IME / Department Bioaccumulation and Animal Metabolism; C. Rauert, Umweltbundesamt / International Chemicals Management; J. Koschorreck, Umweltbundesamt
To assess chemicals for their environmental risk, one characteristic evaluated is the potential to bioaccumulate in organisms. Laboratory derived endpoints have been representing the gold standard. In the light of the 3R principle for animal studies (Reduce, Replace, Refine) and a need for more holistic consideration of bioaccumulation alternative methods are being investigated right now. One of these metrics is the trophic magnification factor (TMF). This endpoint integrates enrichment processes over a food web and is derived from field samples. TMF values are also applied in the context of the Water Framework directive to normalise chemical monitoring results to a common trophic level. The derivation of environmental quality standards for the 'secondary poisoning of predators' goal is another aspect TMF values are important for. Recent reviews show that manifold factors could influence the TMF, accordingly research should be conducted to evaluate the respective impacts. A comprehensive literature evaluation was conducted to identify the requirements for the performance of TMF studies, focusing on freshwater habitats. A sampling campaign which considered many of the findings was successfully performed at lake Templin, Potsdam, Germany. Passive sampling covering the entire sampling period was conducted and plankton samples of different fraction sizes and sampling dates were retrieved. Mussels were collected as representatives of primary consumers (2nd trophic level). Since larger invertebrates are absent in the pelagic food web of lake Templin, fish samples of small and juvenile specimens representing intermediate trophic levels were included. Considerably larger and older fish were collected to provide insight into the upper trophic levels. These fish were divided into filet and carcass samples to allow analyses of both, accumulation and tissue distribution. Furthermore, blank samples of plankton, mussels and fish (filet) were taken. Preparation was performed following ESB cryo-milling and storage standards. Enough sample material for the different trophic classes could be obtained allowing the analyses of the food web interactions. However, the sampling campaign also showed that not all requirements specified for TMF studies in the literature can be applied to any environment. In how far these or other aspects could potentially impact the TMF determination is part of ongoing questions that are currently under investigation using the retrieved samples.

628
Predicted trophic magnification factors for cyclic volatile methylsiloxanes in selected real-world aquatic food-webs
J. Kim, The Dow Chemical Company / Toxicology and Environmental Research and Consulting; K.B. Woodburn, Dow / Toxicology and Environmental Research Consulting; F. Gobas, Simon Fraser University / Resource & Environmental Management; M. Cantu, Simon Fraser University / Resource and Environmental Management
An important aspect of environmental risk assessment is to evaluate the bioaccumulation potential of hydrophobic cyclic volatile methylsiloxanes (cVMS) through dietary exposure pathways. The current study simulated the chemical transfers through real-world food-webs and predicted trophic magnification factors (TMFs) for octamethylcyclotetrasiloxane (D4) and decamethylcyclopentasiloxane (D5). We selected five aquatic food-webs (Lake Erie, USA; False Creek, Canada; Lake Ontario, USA/Canada; Oslofjord, Norway; Tokyo Bay, Japan) and conducted a TMF simulation by using the Multibox-AQUAWEB (MBAW) biomagnification model. In order to reduce uncertainty for the most influential input parameters, such as biotransformation rate constants (k_M) and dietary assimilation efficiencies (E_D), measured values were used in the model instead of estimated ones. For the selected food-webs, all predicted TMFs were shown to be below 1, indicating trophic dilution of the compounds through the dietary exposure pathways. The predictions were generally in agreement with field-measured TMFs for D4/D5. However, there remains some disagreement concerning D5 in some aquatic systems, where field TMFs >1 or < 1 are rather uncertain based on the size of confidence intervals. Thus, it is suggested to investigate whether the chemical transfers in some systems were solely based on the food-web structure or affected by other factors such as environmental conditions (e.g., concentration gradients downstream of wastewater treatment plants).

629
Applying a Weight of Evidence Evaluation for Characterizing the Bioaccumulation Potential of PAHs in PBT Assessment
A.D. Redman, Exxon Mobil Biomedical Sciences, Inc. / Toxicology and Environment Science Division; C. Hughes, Ricardo Energy & Environment / Chemical Risk; Y. Verhaegen, E. Vaiopoulou, CONCAWE; T. Parkerton, ExxonMobil Biomedical Sciences Inc. / Toxicology & Environmental Science
In a general scientific approach, assessment of persistence (P), bioaccumulation (B), and toxicity (T) of chemicals is an important initial step in the characterization of chemical risks in the environment. The science underlying bioaccumulation assessments has evolved over the past 50 years, with the initial focus on limited classes of recalcitrant chemicals that are not broadly representative of chemicals currently in commerce. Recent advances in B science have proposed new methods for evaluating PBT properties. The main goal of these methods are to identify substances with the potential to biomagnify in foodwebs and thus increase potential exposures and associated risks to upper trophic levels, including humans. The present work builds on these recommendations to specifically evaluate the bioaccumulative potential of polyaromatic hydrocarbons (PAH). this presentation will discuss B assessment of PAHs using fish BCF data as well as higher tier B metrics such as BMF and TMF. The behavior of PAH will be contrasted with classic POPs

630
Obstacles in Finding New POPs: Bioaccumulation and Toxicity
H. de Andrade, ETH Zurich / Department of Environmental Systems Science; M. Scheringer, ETH Zurich
The Stockholm Convention (SC) recognizes Persistent Organic Pollutants (POPs) in terms of their persistence (P), bioaccumulation (B), long-range transport potential (LRTP), and toxicity (T). To nominate a new POP, data on specific screening criteria are necessary, such as B and T. Here, we discuss important issues in finding appropriate data for B and T criteria set by the SC. To start a POP candidate nomination, potential POP candidates must be identified. For 9 potential POP candidates with high K_{ow} values, we collected POP-specific data collected from public sources and evaluated this information for data availability and quality. Missing data were then generated with property estimation methods. A large obstacle in the data collection and evaluation was lack of measured B and T values. The core problem was identified as poor consideration of solubility and timescale issues. From a thermodynamic point of view, the solubilization in water is low for high-K_{ow} chemicals. In addition, also uptake via gills or membranes is slow because of the high K_{ow}. To reach relevant concentrations where B occurs and toxic effects are observed, a longer timescale must be considered. The ECHA Guidance on Information Requirements and Chemical Safety Assessment, Chapter R.11, and the OECD Test Guidelines (TG) 305 (B) and 203 (acute T) acknowledge issues in testing low-solubility substances. The current TG 305 explicitly mentions the use of aquatic dietary exposure for very hydrophobic chemicals in B tests, but in actual B tests, dietary exposure is often not considered. Regarding T, TG 203 does not mention dietary exposure and offers limited recommendations for the solubilization of hydrophobic compounds. Beyond the 9 substances considered here, many POP candidates have low to almost no solubilization in aquatic B and T test media. A better way to create aquatic exposure scenarios would be to simulate dietary uptake. The limitations described are a great barrier in a new POP nomination, because the SC prefers experimental data. POP candidates may be left behind if the requested data are not available and/or cannot be generated. It is imperative to develop better standard tests for dietary exposure that accommodate the unique properties of POP-like substances or enforce guideline recommendations. Overall, there is need for more standardized, routine-like applications of new methods. The SC should consider updating its criteria to resolve these issues in B and T assessments.

Communicating Science, Failures, Fortune and Risks to Improve the Value of Environmental Research to Society (II)

631
Stakeholder engagement in environmental risk assessment
W.R. Munns, U.S. Environmental Protection Agency / Atlantic Ecology Division; H. Selck, Roskilde University / Dept Science and Environment; A. Rea, U.S. Environmental Protection Agency / Immediate Office of the Assistant Administrator
Active engagement with stakeholders can improve the value of risk assessments for environmental decision making by addressing three interrelated issues: transparency, objectivity, and communication. Stakeholders should be involved in risk assessments throughout the entire process-from assessment planning and problem formulation (including selection of protection goals and assessment endpoints) to risk communication-to help ensure that assessments are meaningful and informative to the environmental decisions that affect them. Acceptance of assessment results by stakeholders and decision makers depends in part on transparency in how a risk assessment is conducted, including its approaches, methods, assumptions, and uncertainties. Although full engagement by stakeholders in all assessment activities might not be possible or practical, assessments will become more transparent as stakeholder involvement increases. Stakeholders can serve as a check on the objectivity of risk assessments, helping to ensure that the methods employed (or in a worst case, special interests) do not bias results unintentionally or otherwise. They should be viewed as important sources of relevant knowledge about specific environmental systems and how people interact with them, and of the values people impute to those systems. Engagement of stakeholders throughout the process facilitates communication of risk assessment results and the rationale and expected benefits of management decisions based on them. Stakeholder engagement promotes clarity and understanding of the approaches taken during, the results obtained by, and the limitations of risk assessments, and should result in wider acceptance of this tool

as valuable for informing environmental decisions.

632
Reducing Nonpoint Sources of Nutrients via Non-traditional Approaches
A. Rea, U.S. Environmental Protection Agency / Immediate Office of the Assistant Administrator; T. Gleason, US EPA Atlantic Ecology Division / Atlantic Ecology Division National Health and Environmental Effects Research Laboratory Office of Research and Development; W.R. Munns, U.S. Environmental Protection Agency / Atlantic Ecology Division; M. Chintala, US EPA NHEERL / Atlantic Ecology Division; K. Mulvaney, U.S. Environmental Protection Agency / Atlantic Ecology Division ORD NHEERL; S. Horsley, Barnstable Clean Water Coaltion; S. Van Drunick, U.S. EPA; Z. Crocker, Barnstable Clean Water Coalition
Communities in the U.S. are seeking innovative and cost-effective approaches to manage nutrient loading from nonpoint sources in ways that improve environmental and societal conditions. This project focuses on providing watershed-based solutions for nonpoint source nutrient loading that can support communities across the United States and beyond. Our primary objective is to test nationally-relevant approaches for managing nonpoint source nutrient pollution in partnership with the Barnstable Clean Water Coalition (BCWC), a non-governmental organization located in the Three Bays watershed on Cape Cod, MA where nonpoint source nutrient loading is a significant problem. Resolving this issue through installation of public sewer systems, while technologically feasible, is extremely expensive due to the distribution, density, and seasonality of the population on Cape Cod. To best address nutrient pollution in an efficient and economic manner requires understanding the waterbody and its associated watershed and designing tailored management controls. The BCWC is promoting nature-based solutions to reduce nutrient loadings that will achieve its water quality goals quickly and cost-effectively. Objectives for BCWC in this partnership include: 1) solving the nutrient problem in Three Bays in a sustainable and affordable manner; 2) becoming a recognized national model for addressing non-point nutrient management; and 3) becoming a center for education and outreach to support other communities as they address issues of nonpoint source nutrient management. This project supports BCWC and other stakeholders in meeting their goals for restoration and water quality in a manner that is transferable to other systems nationwide. This research contributes directly to the monitoring (performance evaluation of interventions and quantification of corresponding watershed-level responses), modeling (best placement of interventions on the landscape, and effect of interventions on estuarine waterbodies), restoration (cranberry bog test systems and freshwater pond restoration), and social science (economic valuation associated with clean water and tourism; acceptance of various interventions; data visualization and science translation) needs of BCWC to achieve comprehensive and watershed-scale solutions to nonpoint source nutrient loading. Feedback and information gathered at the Problem Formulation Workshop will be presented, as well as ongoing stakeholder engagement activities.

Developing Regulatory guidance that meet Regulatory Objectives and Field Reality: learning from the MAgPIE project
A. Alix, Corteva Agrisciences / Risk Management
The development of regulatory guidance documents that address regulatory needs and protection goals while still reflecting field reality is may be of increase challenge. This reflects at least two aspects of regulatory risk assessment: 1) the increasing scientific knowlegde in the research fields related to a regulatory matter, that results in the increasing awareness of the actual complexity of that scientific area and 2) the increasing involvement and legitimate demand from the general public, for safer chemistries, practices and production systems, which need to be taken into account by decision makers. Yet the resulting complexity in updated regulatory guidance may not be received as a necessary improvement by all stakeholders, particularly in situations where they perceive a disconnection with their own understanding of the issues and their potential solutions. As a consequence valuable knowledge and guidance may simply be ignored, contourned, disregarded with ultimately no benefit for human and environmental protection. Risk mitigation measures are of increasing importance for environmental protection in the area of the use of pesticides in crop protection. In 2012, the question raised multiple exchanges between European authorities, and many initiatives had been undertaken in order to develop, implement and account for risk mitigation measures in the risk assessment procedures. As a result of these exchanges, it was decided to organise a European workshop in order to encourage further the dialog and provide European regulatory authorities a toolbox of risk mitigation measures designed for the use of Plant Protection Products for agricultural purposes. But most importantly, it was felt critical to keep the scientific discussion as open as possible and involve stakeholders to reflect the whole chain of contributors, from risk assessors to end users (farmers). This contribution offers to present the approach followed by the MAgPIE workshop organisers and the process that lead to develop this European risk mitigation toolbox. The MagPIE workshop was organised under the auspices of SETAC and the European Commision.

634
Systematic Maps as tools for the translation of research into regulatory decisions
T. Wolffe, Lancaster University; P. Whaley, C. Halsall, Lancaster University / Lancaster Environment Centre
The volume and breadth of accessible data of potential relevance to chemical risk management is continually growing, as our understanding of the mechanisms underpinning toxicity and our appreciation for the behavior of chemicals in the environment continues to develop. Although this has significant implications for informing regulation, the volume, scope and heterogeneity of this data can present significant challenges for risk assessment and risk management decision-making. In the absence of a sufficiently robust and transparent framework with which to collate and handle this data, decisions makers risk cherry picking evidence and allowing observer bias to steer its interpretation, compromising the translation of research into regulatory action. These challenges have seen an increasing interest in systematic mapping as a tool for regulatory decision making in environmental health. Systematic maps provide the framework needed to collect, process and store all evidence available on a broad research topic, such as the effects of exposure to a chemical substance. They distil a vast, heterogeneous evidence base into an accessible, comparable and easily updated format using transparent and reproducible methodology. Their broad overview facilitates fast identification of emerging trends, including the presence of evidence gaps and evidence clusters, which can be used to target resources more efficiently. This talk introduces the concept of systematic mapping to the chemical risk management workflow, and identifies the highly connected nature of environmental health data to be vital for understanding trends in the evidence base. Current data management practices, which struggle to preserve these connections and therefore limit the value of existing data, will be contrasted to the advantages of adopting graph database technology for systematically mapping the risk assessment relevant evidence base. The applicability of graphical systematic maps to predictive toxicology, and their amenability to advances in machine learning and AI, will also be discussed in the context of challenges faced by regulators; i.e. an ever-expanding pool of chemicals requiring evaluation, increasingly pressed resources with which to conduct evaluations, and the potentially uninformative nature of traditional toxicity tests used to conduct these evaluations.

635
Tailings spills continue to happen: so why do we seem to always get the response wrong?
R. Smith, A. Markham, Hydrobiology Pty Ltd
On November 5, 2015 the Fundao Tailings Dam at the Samarco Iron Ore Mine failed in a liquefaction flowslide. An estimated 32 Mm^3 of tailings plus scoured valley colluvium and alluvium was discharged downstream, initially as a debris flow, along some 680 km of the Rio Doce in Brazil. This was the largest mine tailings spill to date and one that continues to garner international press coverage. We were called in to assist one of the shareholder companies with technical advice on their response within 48 h, but over 3 years later we are still heavily involved in a contentious multi-sectoral, multi-party assessment of the impact and recovery trajectory of the spill. With over 30 years each dealing with tailings releases into water courses, from small to large, in developing countries and developed countries, we conclude that across our experience, such disharmony is prevalent and basic errors continue to be needlessly repeated in the response to spills. We propose that the mining industry as a whole, has not adopted the strategies of preparedness for disaster of the petroleum industry and continues to respond with shock at the occurrence of systems failures leading to spills, and regulators continue to see penalty of those responsible as the favoured response over facilitation of recovery. We propose a paradigm of preparedness and stakeholder collaboration as a much preferred, logical alternative.

636
Can living organisms in bioassays be replaced on enzymes? From idea to commercial products. Problems and advantages.
V. Kratasyuk, Siberian Federal University / Biophysical
Historically, the application of bioluminescence in toxicology began with the usage of luminous bacteria and they are still widely used. As opposed to other test objects such as paramecia, algae, and so on, the luminous bacteria assay is faster (< 30 min). However, as with other organisms, luminous bacteria is petulant. The failure to maintain the stable state of bacterial culture during measurements and storage results in low accuracy of measurement, a clear disadvantage of this method caused by the "petulance". The bacteria react to the toxic substances either by decreasing or by increasing the luminous intensity, often leading to ambiguous interpretation of results. Because of these shortcomings the luminous bacteria assay didn't show reliable results. The new approach to develop the bioluminescent enzymatic biosensors, toxicity bioassays and reagents has been described. To solve the problem of how to detect, identify, and measure the contents of the numerous chemical compounds in environmental monitoring, food product monitoring, and medical diagnostics, the bioluminescent enzymatic toxicity assays were proposed, wherein the NAD(P)H:FMN-oxidoreductase +luciferase substitutes for living organisms. The immobilized reagent Enzymolum was introduced to facilitate and accelerate the development of cost-competitive

enzymatic systems for use in biosensors. Prototype biosensors offer cost advantages, versatility, high sensitivity, rapid response, extended shelf and flexible storage conditions. Due to the coupling with luciferase, it is possible to design new enzymatic bioassays in toxicology and combine them into a set. The set includes key enzymes of metabolic processes such as LDH, trypsin and others. The set of bioluminescent enzymatic toxicity assays was used for monitoring natural and laboratory aquatic ecosystems, soil contamination, as well as for toxicity analysis of pesticides and sanitary assessment of nanomaterials. The new possibilities of enzymatic bioassays are discussed. We are ready to say and discuss the problems which were arising during developing this new approach. At the beginning it was very hard to discuss with our peers use the new perspective as key to our idea. But even now when we win we have problems with understanding of the new approach and wish to show the way and history of developing bioluminescent bioassays from idea to commercial products. The research was supported by the Russian Science Foundation, project No 16-14-10115.

Trans-Disciplinary Research on Coastal Ecosystems of the Northern Europe: Achievements and Problems

637

Diversity and typical structure of salt stratified lakes on the White Sea coast

E. Krasnova, Lomonosov Moscow State University, Faculty of Biology; N.L. Frolova, Lomonosov Moscow State University / Department of Geography; D.A. Voronov, A. Kharkevich Institute for Information Transmission Problems of Russian Academy of Science,; M.V. Mardashova, Center of Marine Research of Lomonosov Moscow State University; S. Patsaeva, Lomonosov Moscow State University / Depament of General Physics

Many coastal lakes and lagoons at different isolation stages were formed on the White Sea coast as a result of isostatic postglacial uplift. Lakes undergo gradual transformation from a sea bay into a continental water body, thereforerepresent different steps of hydrological evolution and ecological succession. Halfway through their evolution,a strong stratification settles up to the meromixis. To date, we have investigated about 20 coastal semi-isolated lakes and lagoons. Bathymetric studies were carried out, vertical profiles of temperature, salinity, pH, ORP, dissolved oxygen, hydrogen sulfide, and nutrients were obtained. Long-term monitoring is being carried out in several lakes in all year seasons during over 10 years. The sharpness of physicochemical gradients and stability of vertical stratification depend on the interaction of freshwater runoff and the frequency of seawater intrusions. Long-term temperature trends have been identified. According to vertical structure data on quite a number of studied lakes, a generalized hydrological scheme was constructed. On the boundary of aerobic and anaerobic zones, colored water layers appear caused by blooming of some eukaryotic microorganisms, including mixotrophs, or anoxygenic phototrophic bacteria. Colored layers enhance sharpnessof physicochemical gradients and make the stratification more stable. As a result of phytoplankton photosynthesis, a layer with extremely high concentration of dissolved oxygen (up to 300% saturation) often emerges in the aerobic zone. The adjoined bottom zone is characterized by a particularly high abundance and biomass of macrozoobenthos. In the lagoons with the regular tides *Macoma balthica* community prevails; while reservoir's isolation increases, it is replaced by *Hydrobia ulvae-Chironomus gr. salinarius* association; in water bodies with freshwater mixolimnion, insect larvae, mainly chironomids, are dominant. Some lagoons have the thickness of all typical water layers enough to form a bottom zone with specific macrozoobenthos associations. The surface water layer with a lower salinity is characterized by the greatest species diversity due to insect larvae varying from year to year. Marine fauna typical for neighboring shallow waters of the White Sea inhabits the bottom depth which contacts to the saline aerobic layer, and the anaerobic zone lacks of macrobenthos.

638

Copper toxic effects on sea star Asterias rubens at different levels of biological organization

A. Poromov, Lomonosov Moscow State University / Department of General Ecology; V. Fedyunin, Lomonosov Moscow State University, Faculty of Biology / General Ecology

The common sea star *Asterias* rubens represents a key-species of the White Sea macrobenthic community. Copper is abundant anthropogenic source metal and one of most toxic in marine sediments. The toxic effects of various concentrations of copper on survival, the behavioral response, changes in cellular elements of coelomic fluid (CF) of starfish *Asterias* rubens and heat shock protein 70 (HSC70) concentration and coelomic cells viability in response to exposure were investigated. Half-lethal concentrations were established for copper (0.98±0.16 μM). Exposure of this metal led to a significant righting time growth. When the sea stars were exposed to Cu it accumulated in the bodies and the number of circulating coelomocytes, increased significantly. Copper exposure resulted in increase agranulocytes and small cells proportion on other side decreasing in the percentage of red amoebocytes (granulocytes) in the CF. In addition, coelomocytes showed stress response in terms of changes in HSP70 levels and as judged by Western blotting. Taken all together, our results confirm the potential of sea stars *Asterias* rubens as bioindicator and their coelomocytes as biomarkers of environmental stress with different sensitivity at different levels of biological organization.

639

Adaptive potential diagnostics in selected marine invertebrates for assessing ecological status (health) of coastal marine ecosystems

T. Kuznetsova, Saint-Petersburg Scientific Research Center for Ecological Safety Russian Academy of Sciences / Lab.Bioelectronic Methods for Geoecological Monitoring; S. Kholodkevich, Saint-Petersburg Scientific Research Center for Ecological Safety, Saint-Petersburg State University, Institute of Earth Sciences; A. Sharov, Saint-Petersburg Scientific Research Center for Ecological Safety Russian Academy of Sciences, Saint-Petersburg State University, Institute of Earth Sciences; A. Kurakin, SaintPetersburg Scientific Research Center for Ecological Safety Russian Academy of Sciences; M. Nicolic, BIO-ICT Centre of Excellence in Bioinformatics, Institute of Marine Biology

The aim of the present paper was to review the results obtained in our previous field and laboratory studies using cardiac monitoring system worked out at Saint-Petersburg Scientific Research Center for Ecological Safety for assessing of biological effects of environmental pollution in a few problem costal seas. The experience of development and approbation of proposed approach to the assessment of biological effects of environmental chemical stress based on evaluation of adaptive potential of indigenous species of the invertebrates from different in anthropogenic pressure fresh water, brackish water or marine areas, with the emphasize on different sea is discussed. The evaluation of adaptive potential of representatives of local biota (mollusks and crustacean) was based on measuring the heart rate recovery time after removal of stress load (50% salinity change). Rapid recovery (less than 50-60 min) signifies a good adaptive potential in different species, indicating good ecological status of the study site they inhabit. The paper presents a number of examples demonstrating how methodology for the evaluation of invertebrate's physiological state can be used in ecosystem health assessment and ecological risk assessment in the Baltic Sea Region, the White Sea,the Black Sea (Crimea) and the Adriatic Sea (the Boka Kotorska Bay). The later approach has been successfully applied in laboratory and mesocosm experiments to assess the toxic effects of hazardous substances on marine organism status and could be a useful tool in screening of biological effects of emerging agents with the unknown mode of action. "The study is supported by the Grant 18-44-920010 "Assessment of the recreational potential of the waters of the Sevastopol region by bioindication methods"\n

Fluorescence and absorption spectroscopy of chromophoric dissolved organic matter (CDOM) in aquatic environments of the Northern part of European Russia

S. Patsaeva, Lomonosov Moscow State University / Depament of General Physics

The colored/chromophoric dissolved organic matter (?DOM) is present in all types of natural water. Its typical concentration in water is low, however the ?DOM is a significant organic carbon reservoir on the Earth, exceeding the organic matter of living organisms. Since the ?DOM of natural origin absorbs the UV and short-wave visible light and therefore emits fluorescence, its optical spectra are successfully used in the tasks of monitoring the natural aquatic ecosystems. For the aquatic CDOM in various types of natural aquatic environments (marine, riverine, stratified relic lakes) such spectral characteristics as the wavelength of the emission maximum in fluorescence spectrum, the fluorescence quantum yield, the spectral dependences of optical density and their higher derivatives are very significant. Spectroscopic measurements were performed to analyze water samples from coastal zones of the White Sea, Baltic Sea, several river and lakes, freshwater and saline, located in Karelia to characterize CDOM origin and to reveal its fluorescent components. Fluorescence quantum yield and emission maximum wavelength were described as a function of excitation wavelength within wide spectral range from 230 to 560 nm. The "blue shift" of fluorescence emission was observed for all the CDOM samples with change in excitation wavelength from 270 to 310 nm. The emission maximum suffered the 'red shift" at excitation wavelengths above 310-340 nm. Fluorescence quantum yield reached maximum at excitation wavelengths about 370 nm and decreased monotonically thereafter. The similarity of spectral characteristics in different freshwater lakes with that observed for coastal and terrestrial CDOM samples revealed that CDOM in coastal zones is composed of a major terrestrial component. Such technique can be successfully used in aquatic ecosystems monitoring. This work was supported by the Russian Foundation for Basic Research (RFBF) under Grant Number 18-016-00078 and by a grant from the "Bazis" Foundation for Development of Theoretical Physics and Mathematics.

Unlike relatives and unrelated doubles in the world of microbes by the example of anoxygenic phototrophic bacteria from the lakes connected to Kandalaksha Bay, White Sea

O.N. Isaeva-Lunina, Winogradsky Institute of Microbiology, Research Center of Biotechnology, Russian Academy of Science; A.S. Savvichev, Winogradsky

Institute of Microbiology, Research Center of Biotechnology, Russian Academy of Sciences, Moscow 119071, Russia; T.V. Kolganova, D.S. Grouzdev, Institute of Bioengineering, Research Center of Biotechnology, Russian Academy of Sciences., Moscow 119071, Russia; V.M. Gorlenko, Winogradsky Institute of Microbiology, Research Center of Biotechnology, Russian Academy of Sciences, Moscow 119071, Russia
The phylogenetic position of anoxygenic phototrophic bacteria from the chemocline zone in stratified lakes connected to the Kandalaksha Bay was investigated. In lake Kislo-Sladkoe we discovered the 100% phylogenetic similarity (p/g sim) of 3 isolatedgreen sulfur bacteria (GSB) morphotypes. One brown-colored (b/c) *Phv*PS10 (GenBank (GB) ??702853) strain with bacteriochlorophyll (BChl) *e* and carotenoid isorenieratene. Two green colored (g/c) (*Chlv*PS10 (GB ??702852) and *Pr*PS10 (GB ??702854)) strains with Bhl *d* and carotenoid chlorobactin. All strains had p/g sim with *Chlorobium phaeovibrioides*: b/c DSM 269^T (Y08105) – 99.3%, and g/c DSM 265 (GB NC_009337) – 100%. Two the same identical strains b/c *Phv*Tcv-s14 (GB MH509941) and g/c*Gr*Tcv13 (GB MH509940) were also found in lake Trekhtsvetnoe. From lagoon on the cape Zeleny a b/c GSB strain ZM (GB PDNX01000007.1) with prosthecas was isolated, which contained Bchl *e* and isoreniaratin. It had almost 100% p/g sim with the g/c *Prosthecochloris aestuarii* DSM 271^T(GB Y07837). Purple sulfur bacteria (PSB) *?cr*PS10 (GB KC702858) and *?m*PS10 (GB KC702856) strains from lake Kislo-Sladkoe were similar and phylogenetically identical, contained carotenoid okenone, could be motile due to a bunch of flagella or nonmotile with gas vacuoles and most resembled the okenone-contained bacteria of *Lamprobacter* and *Lamprocystis* genera. However, p/g sim with ? *Lpb. modestohalophilus* Sivash^{NT} (GB HQ877095) was 93%, with *Lpc. purpurea* (GB NR_119250.1) – 90%. The closest strains were *Thiocapsa*: *Tca. rosea* DSM 235^T (GB AJ006062) spirloxanthin-contained with gas vacuoles – 99.1%, okenone-contained without gas vacuoles *Tca. marina* (GB Y12301) – 99%. Saltwater PSB *Trcc*PS10 strain from lake Kislo-Sladkoe looked like *Thiorhodococcus drewsii.* The main carotenoid was rhodopin, bacterial suspension had a reddish-brown color. However, the strain occupies a separate intermediate position between pink-purple rhodopinal-contained type strain *Trc. kakinadensis* DSM 18858^T (GB AM282561, 98.3% p/g sim) and rhodopin-contained strain *Trc. drewsii* DSM 15006 (GB FM178273, 97.5% p/g sim). Thus, the type of Bhl and carotenoids in GSB, and even the presence or absence of flagella or gas vacuoles in some PSB, do not determine the species of anoxygenic phototrophic bacteria. The work was supported by the RFBR 17-04-01263. The work was carried out using the scientific equipment of Core Research Facility “Bioengineering”.

Chlorophyll fluorescence methods in biomonitoring of water bodies separated from the White Sea
D. Todorenko, Lomonosov Moscow State University / Biophysics; E. Krasnova, Lomonosov Moscow State University, Faculty of Biology; D. Matorin, Lomonosov Moscow State University / Biophysics
Phytoplankton are the primary trophic level of a food chain in aquatic ecosystems. Their functional state, especially photosynthesis, can be affected by ecological factors leading to changes in the entire food web. According to this fact, monitoring of physiological state of phytoplankton assumes ever-greater importance. Its successful implementation should provide an opportunity to detect alterations of the individual levels of ecological systems such as aquatic phototrophs and, based on this, to predict further changes of entire aqueous systems over the time. Particular importance is obtaining a relevant information of cellular metabolism alterations of photosynthetic organisms before morphological symptoms become visible or even before changes in chlorophyll content become apparent. Nowadays, luminescence methods, in particular fluorescence, are being developed to detect alterations of the physiological state of photosynthetic organisms. Approaches based on registration of chlorophyll fluorescence are rapid, non-invasive and non-destructive methods that allow recording an immediate response of photosynthetic organisms to the changes of environmental factors *in situ* due to chlorophyll in the photosynthetic membranes serves as a natural probe of the photosynthetic organisms. There are different principles of registration of chlorophyll fluorescence that permit to investigate the photosynthetic processes at various functional levels (e.g., light-harvesting complexes, primary light reactions, electron transport chain, light-independent reactions in thylakoid stroma, and even slow regulatory processes). For the first time, chlorophyll fluorescence methods were applied in biomonitoring of water bodies separated from the White Sea. Application of chlorophyll fluorescence methods allowed to characterize physiological state of photosynthetic organisms that inhabit separated water bodies, and to reveal features of their photosynthetic behavior.

Linking Models, Experiments and Measurements to Reliably Investigate the Environmental Fate and Effects of Hydrophobic Organic Contaminants and Mixtures (II)

643
Passive dosing and aquatic toxicity testing of complex organic mixtures - Linking toxicity to concentrations in the silicone and lipid donors
L.N. Trac, Technical University of Denmark / Environmental Engineering; P. Mayer, Technical University of Denmark / Department of Environmental Engineering
Environmental hazard and risk assessment of complex organic mixtures is complicated because the individual constituents in the mixture have various physicochemical properties and toxicity. One important experimental challenge is to establish and maintain well-defined exposure concentrations to such mixtures in an aquatic toxicity test. An improved experimental methodology can subsequently lead to a better toxicity assessment. The present study, therefore, aims to (1) enable aquatic toxicity testing of complex mixtures at defined and controlled exposure and (2) provide approaches to assess whether the test mixtures exhibit baseline or excess toxicity based on their concentrations in the silicone or lipid donor. Two passive dosing (PD) methods were applied to dose-response testing of complex mixtures with the fresh water crustacean *Daphnia magna*. The first method used a polydimethylsiloxane (PDMS) silicone rod as donor (i.e. silicone PD), which was placed in the aqueous solution and headspace, whereas the second method used a lipid donor (Miglyol oil) for the passive dosing only via the headspace (i.e., headspace PD, HS-PD). The test mixtures were several petroleum products and essential oils. These mixtures were loaded to PDMS rods and Miglyol oil by weighing to desired mass concentrations (%) in these donors. The exposures to test mixture at the saturation level in the two PD systems were analytically confirmed against the pure test mixtures using headspace GC-MS and it was also shown that these two PD methods cross validated each other. The EC_{50} values for the petroleum mixtures and essential oils in the *D. magna* acute immobilization tests ranged between 5-6 % and 0.6-3.2 % mass concentration, respectively, on the silicone base. The EC_{50} values on a lipid base ranged between 16-32 % for petroleum mixtures and 8.5-39 % for essential oils. The EC_{50} values for all tested mixtures on the lipid base ranged between 85-390 g mixture per kg lipid, which corresponds to 425-1950 mmol kg^{-1} lipid when assuming an average molecular mass of 200 g mol^{-1} for the tested mixtures. These lipid based EC_{50} values were above the reported concentration range of 40-160 mmol kg^{-1} lipid, which thus indicates baseline rather than excess toxicity. The present study provided an improved experimental basis for aquatic toxicity testing and assessment of complex organic mixtures.

644
Thermodynamic assessment of (semi-)volatile hydrophobic organic chemicals in WWTP sludge - combining Solid Phase Microextraction with non-target GC/MS
M. Flyckt-Nielsen, DTU Technical University of Denmark; K. Knudsmark Sjøholm, Technical University of Denmark (DTU) / DTU Environment; T. Bucheli, Agroscope ART / Environmental Analytics; P. Mayer, Technical University of Denmark / Department of Environmental Engineering
Thousands of organic chemicals from households and industry end up in municipal wastewater treatment plants (WWTPs) of which a certain fraction will end up in the sludge[1]. The preferred recycling option in the EU is application on arable soils[2]. However, the sludge can accumulate chemicals and transfer them when applied to the environment and there is thus a need for better understanding the behaviour and fate of hydrophobic organic chemicals (HOCs) during WWTP processes and subsequent treatments of the sludge prior land application. The fate and exposure of a HOC in sludge are closely linked to its chemical activity, which is directly related to its chemical potential[3], and can facilitate comparisons across matrices with different sorbent properties and capacities[4]. Chemical activity can be measured with equilibrium sampling devices that utilize the partitioning of freely dissolved molecules between a matrix and a polymer reference phase until reaching a thermodynamic equilibrium (i.e., the same chemical activity in polymer and sample)[5]. Solid Phase Microextraction (SPME) with a polydimethylsiloxane coated fibre is such a partitioning based method that can be used for measuring chemical activity[6]. SPME can be fully automated, having the advantage of both high throughput and high reproducibility. The method was developed and applied to compare chemical potential of (semi-)volatile HOCs in sludge stages across a WWTP and to determine the reduction in chemical potential (*i.e.* exposure level) of (semi)volatile HOCs during co-composting and sorbent amendment of digested sludge. Generally, chemical activity increased from primary, to secondary, to digested sludge and the level in dewatered sludge was not significantly different from the level in the digested sludge. Co-composting end-treatment was generally effective in reducing the chemical potential of (semi-)volatile HOCs. References:

Effect of lipid digestion on PCBs transfer from microplastics during in vitro digestion

N. Mohamed Nor, Wageningen University & Research / Aquatic Ecology and Water Quality Management; Z. Niu, Wageningen University and Research / Aquatic Ecology and Water Quality Management; A. Koelmans, Wageningen University / Aquatic Ecology and Water Quality Management

Human intake of microplastics through ingestion is not surprising especially since microplastics have been detected in several components of the human diet, including drinking water. It is unknown to what extent exposure of these microplastics would lead to negative effects. While there is some knowledge on particle toxicity effects using in vitro cell line cultures for nanoparticles, and until more recently for microplastics, the potential risks of plastic-associated chemicals as the microplastics pass through the gastrointestinal tract is still uncertain. These particles act as vectors for chemicals (i.e. sorbed contaminants and additives) and the bioavailability of these chemicals during the gut retention time of humans is uncertain. To date, risk assessments of associated chemicals have assumed full release of chemicals from microplastics when ingested. However, the bioavailability of these chemicals depend on chemical transfer kinetics, fugacity gradients and retention times of the particles. To provide a better assessment of the human health risks for plastic-associated chemicals, the mechanisms of chemical transfer from microplastics, as well as the other way around, first needs to be elucidated. We developed an in vitro system, which simulates the small intestinal conditions, to study the chemical exchange kinetics from microplastics. As lipids and plastics are known to have high affinities for hydrophobic organic contaminants (HOCs), a range of PCBs with different hydrophobicities were used as model HOCs to understand the effect of lipid digestion on chemical exchange in microplastics. We compared the differences in the kinetics between two most frequently used polymer types for food packaging, i.e. low density polyethylene (LDPE) and polyethylene terephthalate (PET). Knowledge of these kinetic rates allows us to better understand the proportion of chemicals bioavailable and absorbed in the gastrointestinal tract. After exposure of 3-4 h, about 10-68 % of chemicals may potentially leach out and be bioavailable for absorption based on the scenario of the experiment. As chemical bioavailability also depends on the relative concentrations between the gut fluids and plastic, a systematic evaluation of different scenarios using the derived kinetic parameters from this study would provide insights into the potential risks of plastic-associated chemicals.

PUF Disk Samplers for POPs, Metals and PM in Air: Spatial Scales, Human Health, and Future Research

T. Harner, Environment and Climate Change Canada / Air Quality Research Division; A. Saini, N. Jariyasopit, J.K. Schuster, P. Shahpoury, Environment and Climate Change Canada; A. Eng, Environment and Climate Change Canada / Air Quality Research Division; K. Su, Environment and Climate Change Canada; E.O. Gaga, Eskişehir Technical University; S. Halappanavar, Health Canada

Polyurethane foam (PUF) disk passive air samplers have been widely applied for more than a decade to study semivolatile organic chemicals in air. The samplers are simple to use, cost-effective and their electricty-free operation allows them to be deployed anywhere. The passive sampling approach trades-off temporally resolved data, possible with high volume active air samplers, for spatially resolved data that is relatively easily to obtain over local, regional and even global spatial scales – for instance the Global Atmospheric Passive Sampling (GAPS) network and the Global Monitoring Plan (GMP) of the Stockholm Convention on POPs. In many instances, the spatially resolved data is a more relevant and pragmatic approach for investigating abundances in air, long-range transport behaviours, effectiveness of chemicals management measures (temporal trends), and for validating models. Very recently, the use of the PUF-disk samplers has been extended to investigations of particulate matter and metals in air and linking contaminant burdens with indicators of toxicity for the mixture of chemicals in air (e.g. mutagenicity, cytotoxicity, oxidative potential) by using in vitro and chemical assays. Results are presented from local, regional and global-scale programs employing the PUF disk sampler. These include the PAC-MAN (Polycyclic Aromatic Compounds- Monitoring Air Network) in the oil sands region of Canada, ATOUSSA (Assessing Toxicity of Urban Source Sectors for Air) study in Toronto, and a new GAPS Megacities project that investigates POPs, metals and toxicity across 19 international megacities. Future applications and cross-linkages of the PUF disk sampler are considered including: i.) assessing black carbon, a short-lived climate forcer, in air; and ii.) investigating microplastic burdens and transport in air. Furthermore, a global PUF disk sample bank is being established, covering the period 2010 to present. This PUF disk archive presents an opportunity to investigate a wide range of current and priority contaminant issues over space and time and to inform global emissions and model development.

Time trend comparison of co-located active (EMEP) and passive (MONET) sampling sites monitoring persistent organic pollutants in European air

K.B. White, Masaryk University, RECETOX / Toxicology; J. Kalina, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; P. Kukucka, P. Pribylova, Masaryk University / RECETOX; J. Klanova, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment

Two transnational persistent organic pollutant (POP) air monitoring networks currently operate within Europe: EMEP active (ACT) sampling (NILU) and MONET passive (PAS) sampling (RECETOX). While ACT sampling of POPs in air has been ongoing at several EMEP sites since the 1990s, MONET PAS samplers were deployed in the 2000s as an alternative method to address gaps in monitoring due to their ease of use and lower cost. Unfortunately, the comparability of ACT and PAS sampling data is confounded by uncertainty in the influence of sampling rates and particle-phase dynamics on the recalculation of air concentrations; differences in the duration, volume and frequency of sampling between ACT and PAS networks may also hinder comparability. To address these challenges, we calculated and compared time trends for organochlorine pesticides (OCPs) and polychlorinated biphenyls (PCBs) at the six sites with at least 5 yr of co-located ACT and PAS sampling data (2012–2016): Birkenes (Norway), Kosetice (Czech Republic), Pallas (Finland), Rao (Sweden), Storhofdi (Iceland), and Zeppelin (Norway). ACT air data were obtained from EMEP as monthly aggregate means (ng/m^3). MONET PAS samples are analysed at RECETOX and reported as ng/PUF/sampling period (~84 d). Time trends and halving-times for each site and compound were calculated using the Theil-Sen estimator method. Agreement of corresponding ACT and PAS trends was then estimated using the Mann-Whitney U test. ACT trends for OCPs and PCBs showed strong and significant negative correlations, although certain site and compound exceptions occurred. PAS trends were similar in most cases, albeit with lower strength and significance due to the shorter length of monitoring and less frequent sampling. Agreement of ACT and PAS trends varied by site and compound class with PCBs and HCHs exhibiting the strongest comparability while HCB and pp-DDE were the most prone to disagreement. Since PAS trends were calculated using significantly fewer data (12 ACT samples/yr for 15+ yr vs. 4 PAS samples/yr for 5+ yr), comparability to ACT trends may be improved with additional years of data. Strong agreement between trends for most sites and compounds suggests PAS sampling can be used for long-term air monitoring of POPs where ACT sampling is impractical or unfeasible. However, differences in sampling rates and limitations on recalculation still hinder the direct comparison of individual POP concentrations from ACT and PAS air monitoring networks.

How much do dietary and non-dietary sources contribute to prenatal exposure to BPA and DEHP? A Catalonia (Spain) case study.

M. MARTINEZ RODRIGUEZ, Universitat Rovira i Virgili; J. Rovira, Universitat Rovira i Virgili / School of Medicine, IISPV; R.P. Sharma, Universitat Rovira i Virgili / Departament d Enginyeria Química; M. Nadal, Universitat Rovira i Virgili / School of Medicine, IISPV; V. Kumar, Universitat Rovira i Virgili / Chemical engineering department; M. Schuhmacher, Universitat Rovira i Virgili / Chemical Engineering

Endocrine disruptors (EDs) are chemicals compounds that send confusing messages causing various dysfunctions by mimicking or altering the effect of hormones in the human body. Several EDs such as Bisphenol A (BPA) and di (2-ethylhexyl) phthalate (DEHP), are involved in obesity and diabetes diseases in children. Recent studies have shown evidences that these chemicals can cross the placental barrier making fetal exposure closely related to maternal exposure. The aim of this research is to establish fetus exposure to EDs (BPA and DEHP). To address this issue, recently, pregnant women recruitment has begun. In present work, dietary and non-dietary (dermal, non-dietary ingestion and inhalation) exposure of these women was considered. To estimate prenatal exposure, a physiologically based pharmacokinetic (PBPK) model was adapted for pregnancy. Estimates of exposure from all pathways along with their relative importance were provided in order to establish which proportion of the total exposure came from diet and which from non-diet. Total non-dietary mean values were 0.002 $\mu g/kg_{bw}$/day (0.000; 0.004 $\mu g/kg_{bw}$/day for 5th and 95th percentile, respectively) for BPA and 0.597 $\mu g/kg_{bw}$/day (0.116 $\mu g/kg_{bw}$/day and 1.506 $\mu g/kg_{bw}$/day for 5th and 95th percentile, respectively) for DEHP. Indoor environments and especially dust ingestion were the main non-dietary contributors to the total exposure of BPA and DEHP with 60% and 81%. However, as expected, diet showed the higher contribution to total exposure with >99.9% for BPA and 63% for DEHP. Although diet was considered the primary source of exposure to BPA and phthalates, non-dietary sources need to be more thoroughly characterized because with these sources the first-pass metabolism is lacking, so these may be of equal or even higher toxicological relevance than dietary sources. This work is included in the frame of HEALS project (FP7-603946).

Can the anionic surfactant sodium lauryl ether sulphate (SLES) affect the persistence of the pesticide chlorpyrifos in soil?

T. Pescatore, Italian National Research Council / Water Research Institute; n. ademollo, IRSA-CNR / Water Research Institute; L. Rolando, Water Research Institute - Italian National Research Council / Water Research Institute; A. Barra Caracciolo, National Research Council / Water Research Institute; F. Spataro, Italian National Research Council / Water Research Institute; J. Rauseo, National Research Council / Institute of Water Research IRSA-CNR; P. Grenni, National Research Council of Italy (CNR) / Water Research Institute; L. Patrolecco, Water Research Institute-National Research Council / Water Research Institute

Chlorpyrifos (CPF) is an organophosphate insecticide intensively used in agricultural practices. It is persistent in soils, from which it can reach the aquatic environment. Natural biodegradation can play an important role in its removal from the environment. Surfactants are among the substances that can improve the bioavailability of pesticides for natural microorganisms.They are amphipathic molecules able to solubilize hydrophobic contaminants as pesticides through their incorporation into the hydrophobic core of micelles in solution.Sodium lauryl ether sulphate (SLES) is an anionic surfactant widely used in the underground excavation industry, as it is the main component of foaming agents exploited as lubricants. SLES residual concentrations can occur in the spoil materials reusable as by-products for different environmental purposes, such as mixing to agricultural lands. To date, no studies have been carried out on the possible interactions between this surfactant and pesticides in soils. The aim of this study is the evaluation of the persistence of CPF in an agricultural soil in the presence/absence of SLES. Both the CPF and SLES half-life (DT_{50}) were evaluated and the possible effects on the soil natural microbial community were assessed. For this purpose, several replicated microcosms containing uncontaminated soil (Ctr), soil with only SLES (70 mg/kg) or only CPF addition (2 mg/kg) and soil with both SLES and CPF addition were set-up. At selected times (0,7,14,21, 28 days), soil sub-samples were collected from microcosms to determine their residual concentrations. Analysis of SLES was performed with Methylene Blue Active Substances (MBAS) method, while CPF was analysed with GC-ECD, both preceded by Pressurised Liquid Extraction (PLE) from soil. Microbiological analyses were performed in order to assess microbial abundance (DAPI counts), cell vitality (live/dead method), dehydrogenase activity and structure (ELFA analysis). The results showed that both CPF and SLES concentrations decreased during the experimental time. CPF halving time was not significantly affected by the presence of SLES (DT_{50}10 d when alone *vs*11 d when in the co-presence). Even if, the results highlighted that in the co-presence of SLES, all the microbial populations were favoured in term of abundance and activity because they were able to degrade both the pesticide and the surfactant, showing more versatile metabolic capacities.

MO002

Microbial Fuel Cells (MFCs) for promoting DDE degradation

G. Aimola, A. Barra Caracciolo, Italian National Research Council / Water Research Institute; G. Gagliardi, Università La Sapienza; D. Borello, Università La Sapienza / Dipartimento di Ingegneria Meccanica e Aerospaziale (DIMA); P. Grenni, L. Rolando, Italian National Research Council / Water Research Institute; G. Bagnuolo, Italian National Research Council; G. Garbini, Italian National Research Council / Water Research Institute; V. Ancona, Water Research Institute - Italian National Research Council / Water Research Institute

DDT was one of the most used synthetic pesticide worldwide. It was used in a great variety of applications until 70's when it was forbidden in most countries because of its toxicity and its deleterious impact on the environment. DDE (1,1-dichloro-2,2-bis (4-chlorophenyl) ethylene) is one of the main metabolites of DDT which is produced through biotic degradation in aerobic conditions, abiotic dehydrochlorination and photochemical degradation. It is a polychlorinated compound with a high hydrophobicity, high persistence, high potential of bioaccumulation through the trophic chain. Although the use of DDT has been prohibited for decades, residual DDE concentrations are ubiquitous in the environment. Recently, several bioremediation technologies (e.g. using plants and fungi) have been developed to remove DDT and DDE. Among green technology, the use of Microbial Fuel Cells (MFCs) is a promising one for stimulating pollutant bioremediation based on the conversion of the energy stored in the chemical bonds of organic compounds into electrical energy. This study is focused on the effectiveness of MFCs in improving degradation of DDE in soils stimulating exo-electrogen microorganisms that catalyze oxidation and reduction reactions at two electrodes (anode and cathode). Bacterial populations tend to develop making a biofilm producing electrons and protons at the anode, which it used as an electron acceptor under anaerobic conditions. Electrons flows from the anode to the cathode through an external circuit that connects the two electrodes and thus create current. Protons flow through the soil to the cathode where, in aerobic conditions, electrons and protons react with oxygen to produce water. In this study, 4 experimental conditions using MFCs (open circuit) have been carried out (3 replicates each) for evaluating DDE biodegradation: soil, soil + compost, soil + DDE, soil + compost + DDE. Moreover the last 2 conditions were tested both using opened and closed circuit through different electrical resistances to obtain the maximum power value corresponding to the highest DDE degradation rate. Control soils (without MFCs) were used as controls. Chemical and microbiological (microbial abundance, cell viability, DHA) analyses and electrical measurements have been performed at three sampling times: 0 day, 2 months and 4 months.

MO003

IDENTIFICATION OF BACTERIA INVOLVED IN SODIUM LAURYL ETHER SULPHATE BIODEGRADATION IN CONDITIONED SOIL FROM A TUNNELLING CONSTRUCTION SITE

L. Rolando, Water Research Institute - Italian National Research Council / Water Research Institute; P. Grenni, National Research Council of Italy (CNR) / Water Research Institute; J. Rauseo, National Research Council / Institute of Water Research IRSA-CNR; L. Patrolecco, Water Research Institute-National Research Council / Water Research Institute; A. Barra Caracciolo, National Research Council / Water Research Institute

The anionic surfactant Sodium Lauryl Ether Sulphate (SLES) is the principal component of several commercial foaming products for soil conditioning in the tunnelling industry. Huge amounts of soil debris are produced during the excavation process and the presence of SLES can affect the re-use of the spoil material as a by-product. SLES biodegradability is a key point for the re-use of the excavated soil. Recent studies showed that SLES degradation depends on the presence of natural microbial populations colonizing the spoil material in the temporary deposit in the construction site. However, the degradation rates are affected by site-specific conditions consequently SLES persistence can vary under different environmental conditions.The aim of this study was to identify SLES degrading bacteria and to explore their bioremediation capacity. Enrichment cultures were performed using as inoculum bacterial populations from spoil material collected in a tunneling construction site. Approximately 0.5 g of soil (wet weight) was added to 50 mL of minimal medium (MB) enriched with different concentrations of SLES (25, 50, 100, 200 mg/L). All replicates and treatments were treated separately for isolation purposes. SLES degraders were grown in the dark on a shaker at 130 rpm for 7 days at 28°C. Subsequently, 500 mL of the pre-grown cultures from each condition were transferred to fresh SLES enriched media (50 mL) for another 7 days. Appropriate un-inoculated sterile controls were also maintained throughout the experiment. Both SLES concentration and microbial growth were measured. After seven days the highest optical density was observed in the culture medium enriched with 200 mg/L of SLES, therefore it was decided to use this concentration for the isolation experiment. 99% of SLES was biodegraded in just 24 hours. FISH analysis showed that microbial cells involved in the biodegradation belonged to Gamma-Proteobacteria. DNA was extracted and the sequencing of the isolated strain is in progress. The possibility to isolate a natural bacterial strain able to degrade SLES has great potential to be used for bioaugmentation purpose in order to shorten the residence time of spoil materials in the construction sites.

MO004

Bioavailability and cometabolism of pyrene in chemotactic bacteria

L. Rolando, Water Research Institute - Italian National Research Council / Water Research Institute; J. Vila, Consejo Superior de Investigaciones Científicas / Department of Microbiology; R. Posada, J.C. Alcántara, IRNAS CSIC / Agroquimica y Conservacion del Suelo; A. Barra Caracciolo, National Research Council / Water Research Institute; J. Ortega-Calvo, Instituto de Recursos Naturales y Agrobiologia / Agroquimica y Conservacion del Suelo

Polycyclic aromatic hydrocarbons (PAHs) are poorly available in soils due to their interaction with the soil matrix. Bacterial chemotaxis promotes the contact probability between degrader organisms and pollutants, increasing bioavailability and thus biodegradation rates.*Pseudomonas putida* G7 is able to use naphthalene as growth substrate, and responds chemotactically to naphthalene and salicylate, a common intermediate in PAH metabolism,showing smooth movement and positive taxis. We used strain G7 as a model organism to evaluate the potential role of motility in the bioavailability of adsorbed high molecular weight PAHs. We conducted batch incubations of strain G7 in mineral medium with ^{14}C-labelled pyrene loaded on silicone o-rings, which acted as a passive dosing system.
The time course evolution of the ^{14}C-pyrene equivalents in culture fluids revealed a linear increase in the presence of G7, achieving concentrations well above the equilibrium concentration observed in abiotic controls. This phenomenon could only be explained by an active biological process. HPLC quantification revealed that in the presence of strain G7 the final concentration of pyrene in the water phase did not change in the presence of salicylate, but it was well below that observed in abiotic controls, indicating the transformation of pyrene into water-soluble metabolites.Interestingly, strain G7 was unable to mineralize pyrene (< 0.1%), indicating that this was a cometabolic reaction. To evaluate the adsorption

of pyrene to cell surfaces, culture fluids were centrifuged and supernatants and bacterial cells were analyzed independently. Only after 48 h a major fraction of ^{14}C-label was detected in the pellet, indicating the sorption of pyrene to bacterial cells. In sand-filled percolated columns we tested how salicylate influenced bacterial transport through a change in motile behavior and promoted accessibility of strain G7 to distantly located ^{14}C-pyrene, dosed in o-rings. Compared to chemoeffector-free controls, salicylate significantly stimulated bacterial transport. The concentration of pyrene in column effluents evidenced that the bacteria were mobilized to the distant pyrene source. Our results indicate that bacterial motility and chemotaxis could be relevant for long-distance bacterial transport in soils, and contribute to cometabolize poorly bioavailable contaminants. This may have implications for the development of more efficient bioremediation strategies.

MO005

Combined effects of biosurfactants and sunflower rhizosphere on the bioavailability of slowly desorbing PAHs in contaminated soil

R. Posada, IRNAS CSIC / Agroquimica y Conservacion del Suelo; J. Garcia, M. Cantos, Instituto de Recursos Naturales y Agrobiologia de Sevilla CSIC; J. Ortega-Calvo, Instituto de Recursos Naturales y Agrobiologia de Sevilla CSIC / Agroquimica y Conservacion del Suelo

Polycyclic aromatic hydrocarbons (PAHs) are the best representatives of chemicals for which specific limitations in bioremediation exist due to low bioavailability. With the objective of enhancing solubilization and consequently decreasing the fraction of bioavailable pollutants, we integrated in a greenhouse experiment different agents to improve bioavailability: microorganisms, plants (sunflowers) and biosurfactants (rhamnolipids R90) in a PAHs contaminated soil with a total concentration of PAHs of 500 mg/kg. These agents can be used sequentially to act on bioavailability, following low-risk bioremediation approaches to treat slowly desorbing chemicals (Environ. Technol. 21, 1099-1110, 2000; Soil Biology and Biochemistry, 57, 830-840, 2013; Environ. Sci. & Technol. 45, 3019-3026, 2011). To measure bioavailability of PAHs we used desorption extraction with Tenax during 20 h (ISO 16751). The contamination level had not significant effects on the plants either seed germination, plant development or flowering. In consequence, sunflower plants tolerated these conditions, confirming their ability to grow in contaminated soils. Measurement of total PAH concentrations showed a decrease by 90 % after 75 days in planted and control treatments. The bioavailable PAHs concentration also declined during this period, indicating that biodegradation efficiently removed most of the fast desorbing chemicals. However, a slight increase in bioavailability was observed in planted soils at day 75, possibly due to plant root decay. Rhamnolipid was therefore added at this point to enhance the biodegradation of the slowly desorbing fractions, once the sunflower plants completed their growth period in the assayed greenhouse conditions. No significant effects were observed by this addition on the decline of total PAH concentrations, however, a significant increase in the rapidly desorbable fraction was observed after rhamnolipid addition in planted soils, what did not occur without plants. Therefore, the biosurfactant made potentially bioavailable a significant fraction of the slowly desorbing PAHs, only when the soil had supported the growth of plants, which possibly released root components or exudates that promoted the biosurfactant action. The positive effect of sunflower roots on soil microorganisms was strongly enhanced when rhamnolipids were added, as a significant increase of dehydrogenase activity in the soil was detected.

MO006

Role of motility behavior in the dispersal of pollutant-degrading bacteria through restricted porosities

J.C. Alcántara, IRNAS CSIC / Agroquimica y Conservacion del Suelo; A. Akbari, McGill University / Deparment of Civil Engineering; S. Ghoshal, McGill University / Civil Engineering; J. Ortega-Calvo, Instituto de Recursos Naturales y Agrobiologia / Agroquimica y Conservacion del Suelo

The controlled dispersal of motile bacteria through contaminated soils is currently considered as one of the most promising aspects in bioremediation.The difficulty caused by the heterogeneous distribution of the pollutants and the degrading bacteria can be overcome by the use of different chemoefectors. These compounds allow the control over bacterial tactic motility processes, what results in an increase in the efficiency of the microorganisms dispersion and subsequently, enhanced biodegradation rates (*Environ. Sci. Technol*. 42: 1131-1137, 2008; *Environ. Sci. Technol*. 46: 6790-6797, 2012). A bioreactor system was used, where pollutant bioavailability can be evaluated by means of two chambers separated by a membrane with specific pore sizes. This system allows the study of the role of bacterial plasticity on the penetration through pores that are even smaller than the cell size (*Environ. Sci. Technol. Lett.* 3: 399-403, 2016). The purpose of the present study was to evaluate the behavior of chemotactic bacteria (*Pseudomona putida* G7; cell dimensions: 1 μm x 3 μm) in this system, using different membrane pore sizes (from 0.4 to 12 μm), and determining their dispersal and biodegradation capacity through mineralization tests with the ^{14}C-labelled contaminants. Results are presented here on the first part of the study, focused on bacterial dispersal. This innovative system enabled the control of the experimental conditions to establish specific size ranges to which the bacterium could access the contaminant through a modified motility behavior, including hypermotility (glucose) and chemoattraction (naphthalene and salicylate). The most relevant result in this study was that *P. putida* G7 responded positively to the chemoattractant provided through the membrane pores, crossing the membrane in many cases at higher rates than the control. Penetration depended, however, on cell density and chemoeffector concentrations, and subsequently, on the location of the gradients across the membrane. Progress in this field will undoubtedly open up new possibilities for bioremediation processes in contaminated soils, improving the existing techniques for the treatment of poorly bioaccessible contaminants.

MO007

Rhizoremediation halflives of PCDDs and PCDFs obtained in a greenhouse experiment with seven plant species

E. Zanardini, University of Insubria (Como) / Department of Science and High Technology; E. Terzaghi, University of Insubria (Como) / Department of Science and High Technology, Como; G. Raspa, Sapienza University of Rome / Department of Chemical Engineering Materials and Environment; C. Morosini, University of Insubria / Department of Science and High Technology; F. Mapelli, University of Milan- DeFENS / Department of Food, Environmental and Nutritional Sciences; L. Vergani, University of Milan / DeFENS; S. Borin, DeFENS University of Milan / Department of Food, Environmental and Nutritional Sciences; S. Armiraglio, Municipality of Brescia / Museum of Natural Sciences; V.M. Sale, S. Anelli, P. Iavazzo, P. Nastasio, ERSAF; A. Di Guardo, University of Insubria / Department of Science and High Technology

In the last two decades there has been a growing interest in bioremediation technologies which use plants and microorganisms to enhance persistent organic pollutant degradation such as PCB, PCDD, PCDF in contaminated sites (rhizoremediation). Different studies have been conducted to investigate the potential of plant-microbe interactions in the remediation of organic chemical contaminated soils with respect to natural attenuation, providing useful data such degradation halflives. Such a type of data can be used to predict soil concentration temporal trends and the time needed to achieve threshold limits when using plants and their associated rhizosphere microbe to remediate contaminated sites. Although many studies are available for PCBs, few works focus on PCDD and PCDF. In the present work a greenhouse experiment was performed with an aged contaminated soil coming from a National Relevance Site (SIN) located in Northern Italy (SIN-Brescia Caffaro). The soil was characterized by higher concentrations of PCDFs compared to PCDDs, due to higher furan impurities produced during PCB production of the Caffaro Factory. 10 different treatments (combination of 7 plant species and different soil conditions) were considered together with the appropriate controls (soil without plants). Soil and plant biomass were analysed at the beginning of the experiment (t0) up to 18 months (t18). The obtained soil concentrations were used to calculate concentration reduction with time and the corresponding rhizoremediation halflives. The halflives obtained for the most efficient treatments were compared to natural attenuation halflives to evaluate the goodness of rhizoremediation. This study contributed to establish a rhizoremediation half-life dataset for PCDD/Fs

MO008

Bioremediation of diesel-oil contaminated soil with less labor, energy and material by foam and holes

R. Bajagain, P. Gautam, Kunsan National University; S. Jeong, Kunsan National University / Department of Environmental Engineering

Petroleum hydrocarbons present in unsaturated deeper soil are especially challenging for the remediation because of uneven delivery and poor contact of reagents with contaminants. The main objective of this study was to enhance the total petroleum hydrocarbon (TPH) removal efficiency within 30-cm deep soil by improving delivery of remedial agents. A column experiment for enhanced bioremediation of 30-cm unsaturated diesel contaminated soil was performed by combining chemical oxidation foam with bioaugmentation foam by means of delivery through the holes. In landfarming microcosm test, when 5% H_2O_2 and 50 mN $Na_2S_2O_8$ solution (0.2 PV of both) were used for 5-cm TPH contaminated soil in tank (24 cm × 17 cm × 16 cm), TPH oxidation efficiencies were 32 and 33% respectively, whereas the removal efficiencies were increased to 80 and 86% after biodegradation using bioaugmentation solution mixing. For the column tests, three columns (25 cm diameter, 70 cm length) were used having 30-cm thick soil and three vertical holes were installed at triangular points. After 0.2 PV of H_2O_2 and $Na_2S_2O_8$ foam spraying pretreatment, the vertical TPH oxidation efficiencies of the soil were in the range of 49.3-53.1%, 47.4-52.8% and 41.2-43.8% from 5, 15 and 25 cm respectively. Two days after oxidation foam spraying, the periodic bioaugmentation foams were sprayed every second day for four weeks (total 1 PV solution). After one month, the concentration of TPH in the soil decreased to 628 mg/kg (90.6% removal efficiency) from 5 cm depth, while 87.8 and 87.6% of TPH were removed from 15 and 25 cm respectively. This study showed that oxidation-bioaugmentation foam spraying using vertical holes improved the distribution of remedial agents throughout the soil with similar pH, higher water content and microbial population as compared to control test. The kinetic study also revealed that a similar and elevated TPH biodegradation rates can be obtained from all soil depths by using this method. (This work was supported by the

National Research Foundation of Korea(NRF) grant funded by the Korea government (MSIT) (No. 2018R1A2B6006139))

MO009
Microbial diversity and activity of an aged soil contaminated by polycyclic aromatic hydrocarbons
G. Zhao, Information center of MWR, China
In-depth understanding of indigenousmicrobial assemblages resulted from aged contamination by polycyclic aromatic hydrocarbons (PAHs) is of vital importance in successful in situ bioremediation treatments. Soil samples ofthree boreholes were collected at 12 different vertical depths. Overall, the dominating three-ring PAHs (76.2%) were closely related to distribution patterns of soil dehydrogenase activity (DHA), microbial cell numbers and Shannon biodiversity index (H') of indigenous microorganisms. High-molecular-weight PAHstends to yield more diverse communities. Results from 16S rRNA analysis indicated possible functional groups of PAHs degradation include three species in *Bacillus cereus* group,*Bacillus* sp. SA Ant14,*Nocardioides sp.,*and *Ralstonia pickettii.*Principal component analysis (PCA) indicates significant positive correlations between the content of high-molecular-weight PAHs and the distribution of *Bacillus weihenstephanensis*KBAB4 and *Nocardioides sp*. The species *Bacillus cereus*03BB102, *Bacillus thuringiensis,Bacillus weihenstephanensis*KBAB4, and *Nocardioides sp.* were recognized as main PAH degraders and thus recommended to be utilized in further bioremediation applications.The vertical distribution characteristics of PAHs in soil profiles (1-12 m) and the internal relationship between the transport mechanisms of PAHs and the response of soil biological properties help further understand the microbial diversity and activity in an aged site.

MO010
BIODEGRADATION OF HYDROCARBONS BY FUNGI IN SOILS CONTAMINATED BY GASOLINE
C.H. Soares, Universidade Federal de Santa Catarina / Biochemistry Department; N. Coelho Silva, UFSC / Biochesmistry
The infiltration of petroleum products into the soil from leaks and acidental spillages is a serious problem for the environment, since it is composed of toxic elements that have great mobility. Among them are the monoaromatic hydrocarbons that are the volatile organic compounds: Toluene, Ethylene, Benzene and Xylenes (BTEX). In view of the above, the work aimed to use two species of fungi to biodegrade the BTEX compounds in soil, analyzing their behavior, through chromatographic analysis and enzymatic activity of laccase, glycosidase and total proteins. The following species of fungi were used: *Lentinus edodes* and *Pleurotus ostreatus*. In order to verify the behavior of the fungi in soil degradation of BTEX, five contamination simulations were carried out in which there were soil contaminated, soil with a 10% nad 15% increased in *Pleurotus ostreatus,* soil with 10% and 15% increased in *Lentinus edodes*, the soil with a 15% and five simulations were carried out in soil without contamination containing the same proportion of fungi that were in soil with contamination. It was verified that the development of the fungi was quite satisfactory in the contaminated soil, developing more quickly and more intensely than in the soil without contamination. Chromatographic analysis revealed a potential mean of HC biodegradation by fungi

MO011
Evaluation of the toxic effects of sawdust used to phosphorus recovery of a eutrophic aquatic environment: a possibility to ensure global food security
G. Pantano, Federal University of Sao Carlos / Chemistry; T.H. Rocha, P.S. Fadini, UFSCar / Chemistry; A.A. Mozeto, Federal University of Sao Carlos / Chemistry
Introduction: The use of sawdust as biosorbent to phosphorous, for posterior use in agriculture, is a possible solution to ensure water and global food security through a scenario of water bodies eutrophication and phosphate rock depletion. Considering the use of phosphate enriched sawdust as an agricultural fertilizer the aim of this work was to evaluate the toxicity of sawdust after phosphorus adsorption by tests using the lettuce plant (*Lactuca sativa*) to determination the germination index and the size of the radicle and hypocotyl. To evaluate the potential risk of human infection and animals by pathogens, the determination of helminth eggs was also performed in sawdust. **Methods:** The Petri dishes containing twenty lettuce seeds at the control soils (tropical artificial soil) and at amended soils (tropical artificial soil with an addition of sawdust up to 1% (m/m)) were kept in BOD chamber at 22 °C for 120 h. The experiments were carried out in triplicate. They were watered to keep the soil at about 60% of its water-holding capacity. The germination index and the radicle and hypocotyl lengths of lettuce were determined. The determination of helminth eggs was done using the concentration method; this is a modified USEPA method using $ZnSO_4$ solution. **Results and discussion:** The results of the lettuce seed germination bioassays showed that have not impact of sawdust on germination; the germination index was the same for control and amended soils, 92.5%. The results showed that there was no significant difference ($p < 0.05$) in radicle and hypocotyl length of control and amended soils. The radicle and hypocotyl lengths for the control soil were 28.90 ± 1.01 and 35.98 ± 1.88 mm, respectively. For the amended soils were 27.18 ± 0.98 and 34.46 ± 1.61 mm, for the radicle and the hypocotyl lengths, respectively. The helminth eggs were not found in the sawdust. **Conclusion:** In this study phytotoxic effects on lettuce and infection risks to humans and animals of due the presence of helminth eggs were not identified. This reinforces the use potentiality of sawdust as a biosorbent aimed at phosphorus recovery aiming soil fertilization and plant nutrition. **Acknowledgments:** São Paulo Research Foundation, FAPESP (Process 2016/00490-6). **References:** Pantano G, Ferreira JS, Aquino FWB, Pereira-Filho ER, Mozeto AA, Fadini PS (2017), Environ Sci Pollut 24: 2685; Lutterbeck CA, Kern DI, Machado ÊL, Kummerer K. MO012
Soil Amendments' Influence on Microbial Diversity, Pesticide Degradation and Leaching of Nutrients
M. Siedt, RWTH Aachen University, Institute for Environmental Research / Molecular Ecology of the Rhizosphere; K. Smith, A. Schaeffer, RWTH Aachen University / Institute for Environmental Research; J. van Dongen, RWTH Aachen University / Molecular Ecology of the Rhizosphere
Soils have a key function in providing a multitude of ecosystem services, many of them linked to their microbial community. Sustainable soil management is necessary when aiming to preserve biodiversity on the one hand whilst maintaining productive farming on the other. Due to the importance of soils for food production, farmers are interested in soils being fertile, easy to manage, and that are efficient in water and nutrient cycling. However, pesticides and excess nutrients are major threats to the integrity of soils, and due to leaching and run-off of the pollutants, also for adjacent ecosystems. Organic matter is a structurally and functionally important part of the soil. With its diverse molecular structure the organic material is able to sorb nutrient surpluses, pesticides and their metabolites, as well as other pollutants like antibiotics from livestock. Furthermore, an increased organic matter content enhances microbial activity and subsequently improves nutrient cycling and the degradation of pollutants in the soil. Organic material also improves the air- and water balance in soil and can reduce erosion. Optimal soil conditions can even lead to a reduced need of pesticides and fertilizer, and thus contribute to a sustainable management and protection of surrounding environment in the long-term. Our aim is to investigate the influence of different organic soil amendments on microbial biodiversity, pesticide degradation and nutrient leaching in an agricultural soil. We will compare the impact of such amendments on the degradation of the radiolabeled pesticides metalaxyl and MCPA, which are used as a tank mix in potato cultures, and on the leaching of nutrients and pesticides. Microbial communities of bacteria and fungi will be analyzed in parallel via genome sequencing. Finally, based on these endpoints the most promising amendment will be tested under field conditions to assess the applicability of the laboratory results to agricultural management. **Acknowledgement** This research is supported by the Federal Agency for Nature Conservation (BfN, Germany).

MO013
The effect of biochar physico-chemical properties on the sorption behaviour of conazole fungicides
L. Skulcova, Masaryk University, RECETOX / Research Centre for Toxic Compounds in the Environment (RECETOX); L. Bielska, Masaryk University RECETOX; N. Neuwirthová, Masaryk University Faculty of Science RECETOX; J. Hofman, Masaryk University, RECETOX / Faculty of Science, RECETOX
Pesticides are an indispensable part of modern agricultural management, contributing to food security and safety. On the other hand, their extensive use may result in soil contamination as well as surface water contamination, both associated with negative impacts on non-target organisms. Thus, soil remediation amendments are sought-after to counteract the presence of contaminants in soil and/or to minimize their transfer into surface water. Biochar, the product of thermal decomposition of biomass under oxygen-limited conditions, has excellent sorption properties, which make it a valuable sorbent and a suitable alternative for treatment of contaminated soils. Moreover, biochars application to agricultural soils has been shown to increase soil fertility, mainly due to improved nutrient and carbon availability, protection of microorganisms and increased water holding capacity. However, despite these benefits, very little biochar is currently utilized as a soil amendment for either the control of contamination or for improving soil quality, mainly because the consequences of its use in soil are still not well understood. Therefore, the objective of this study was to characterize the effects of biochar physico-chemical properties on the sorption behaviour of conazole fungicides (i.e. epoxiconazole and tebuconazole) and to better understand the relationship between biochar production conditions and biochar origin and sorption of these model pesticides. For that purpose, sorption experiments were carried out using biochars produced from various biomass waste materials (e.g. rice husks, wood chips, cherry stones, chicken manure, etc.) with slow and fast pyrolysis (10 and 30 minutes) under a range of pyrolysis temperatures (300 – 750°C).We assume that apart from the mechanistic understanding of pesticide-biochar interactions, the study contributes to a better biochar management in agricultural with respect to biochar designing, production and dosing.

MO014

Humic acids impact on bioactivity of iron ions and nanoparticles

Y.V. Kovaleva, L. Bondarenko, Moscow Aviation Institute; P. Uchanov, Institute of Ecology and Evolution RAS / Laboratory for soil ecological functions; E.V. Fedoseeva, Pirogov Russian National Research Medical University / Pediatric faculty; V. Terekhova, Lomonosov Moscow State University / Lab of Ecotoxicological Soil Analysis; K. Kydralieva, Moscow Aviation Institute

At present the question still remains whether the toxicity of iron oxide nanoparticles (NPs) from the released ions or NPs itself arises. In this study, behaviors of Fe_3O_4-NPs and iron ions (Fe^{2+} and Fe^{3+}) in the presence of humic acids (HA), an natural organic polyligand that easily coordinate to iron (II, III) ions and graft to NPs surfaces, were investigated in the aspects of their toxicity to *Sinapis alba* and *Paramecium caudatum*. The Fe(II, III)-humic complexes were prepared by reaction of weighed amounts of the HA and the iron source with HA:Fe ratio of 1:0.150 (w/w). Colloidal Fe_3O_4-NPs were synthesized by a chemical precipitation method *in situ* when the magnetic particles are grown within the HA matrix that provides steric stabilization of the colloidal system. Several treatments of the test cultures were made: a) control A – tap water without Fe and HA; b) control B − tap water with Fe (II) or/and Fe(III), c) control C − tap water with HA, d) five treatments with the following substances: Fe(II, III)-HA: Fe(II)-HA, Fe(III)-HA, Fe(II, III)-HA, Fe_3O_4-NPs and Fe_3O_4-NPs-HA. Endpoints (EC50) and threshold level (EC20) for samples with acute toxicity have been studied in test systems with *S. alba* and *P. caudatum*. According to toxicity decreasing for both test cultures the studied samples can be arranged in the following order: Fe(II), Fe(II, III) ≥ Fe(III) >HA >Fe_3O_4-NPs-HA >Fe(III)-HA >Fe(II)-HA ≥ Fe(II, III)-HA >>> Fe_3O_4-NPs. Fe(II) and/or Fe(III) ions and HA clearly demonstrated increased toxicity with respect to root length of *S. alba* seedlings and mortality of *P. caudatum*. Combination of Fe (II and/or III) with HA lead to mitigation of toxicity. The Fe_3O_4-NPs in some concentrations stimulated the survival of ciliates and the growth of higher plants. We suppose that the observed low toxicity for Fe_3O_4-NPs is due to the released metal ions into the supernatant. In case of the Fe_3O_4-NPs-HA treatment, the disperse system effect as a whole is affected. Interpreting the results was performed by a two-way ANOVA with interactions using XLSTAT Software, 2014. The treatment method (single HA, single NPs or their mixture) and the treatment concentration have a significant effect on acute toxicity samples. For both Fe_3O_4-NPs and Fe_3O_4-NPs-HA the toxicity more largely depend on the treatment concentration. Acknowledgement. MO015

Weed based bioformulations to improve phytomediation of oil-polluted soils

K. Kydralieva, Moscow Aviation Institute; I. Kozlov, Institute for Civil Defense and Emergencies, Emergencies, Ministry; Y.A. Nishkevich, JSC Varioganneft

Screening, collection, identification and expression of stable and technological microbial strains living in the rhizosphere of weed − couch-grass *Elytrigia repens* L.were conducted. Rhizobacteria (RB) were isolated from soil samples in sanitary-protective zone of Variogan oil deposit (Tyumen region, Russia). A total of ca. 100 RB isolated were assessed for biocontrol activity *in vitro* against phytopathogenic fungi incl. *Fusarium culmorum*, *F. heterosporum*, *F. oxysporum*, *Drechslera teres*, *Bipolaris sorokiniana*, *Piricularia oryzae*, *Botrytis cinerea*, *Colletothrichum atramentarium*, *Cladosporium* sp. and *Stagonospora nodorum.* Biocontrol activity was performed using four methods: inoculation by radial and parallel streaks and by block and lawn. A culture collection comprising 64 potential biocontrol agents against wheat and barley root diseases has been established.RB isolatedhave been studied at both bioassay and laboratory vegetation experiments. All the experiments confirmed not only high antagonistic potential of those RB in relation to pathogenic fungi but also their plant growth-promoting activity. As a result, four bacterial strains were chosen as a core of pure cultures collection with high fungicidal and plant growth-stimulating potential. Partial determination of nucleotide sequence of 16S ribosomes of tested bacteria indicated that *Pseudomonas* and *Bacillus* species were the most dominant bacteria exhibiting biocontrol activity. Technology to establish liquid and dry microbiological formulations using beneficial RB has been developed. Potassium humate was used in combination with bacteria cells to protect thermolabile RB cells at concentration, drying and long-term storage. Humic substances have proved to be an excellent matrix for immobilization of cells due to its biocompatibility, non-toxic nature, reduced vulnerability to environment stresses which will provide prolonged action of bacterial preparation in field conditions. Biological tests on bioproduct quality towards barley seeds demonstrated an increase in the dry weight of shoots, roots, total biomass to 20, 80, and 30 % accordingly in comparison with the control (no inoculate). Obtained results demonstrated that approach applied was promising in terms of producing weed-isolated RB enriched with humics. Further study aiming to estimate its oil-degrading properties and evaluation of its production at industrial scale are needed.

MO016

Sorption of ciprofloxacin using humics-coated Fe3O4 nanoparticles

K. Kydralieva, L. Bondarenko, Moscow Aviation Institute; S. Bratskaya, Y. Privar, Institute of Chemistry, Far-East Branch, Russian Academy of Science; G. Dzhardimalieva, Institute of Problems of Chemical Physics, Russian Academy of Science

In recent decades, water quality became a crucial issue also in developed countries due to identification in surface and drinking waters of new classes of pollutants, which were previously ignored. Among them antibiotics are of great concern due to their increased consumption, long-term stability in water and soil, and poor efficiency of recovery at conventional water treatment facilities. Ciprofloxacin (CIP) is a fluoroquinolone antibiotic with a broad spectrum of action, which is more often found in surface and wastewaters as compared to other antibiotics. One of the most commonly used method for the removal of CIP from wastewater is adsorption. This study is aimed to estimate surface-dependent effect of humics-conjugated magnetite (Fe_3O_4-HA) on sorption of ciprofloxacin. The nanoparticles of magnetite were synthesized *in situ* by oxidative alkaline hydrolysis of the iron (II, III) powder precursors into humics medium. The synthesized particles prepared at different humics concentration (10, 20, 40 wt%) were characterized using X-ray powder diffraction (XRD), scanning electron microscopy (SEM), Mossbauer and FTIR spectroscopy, DLS and BET analysis. The CIP recovery was studied from 0.1 mM solution at solid:liquid ratio 1:1000, pH 7.5, and the contact time 24 h. The equilibrium concentration was determined spectrophotometrically. The results showed that the size and specific surface of nanoparticles depended upon the humics concentration. XRD results indicate that the addition of HS into Fe_3O_4 nanoparticles media have not changed the crystal structure of nanoparticles, but the intensity of the peaks is reduced with using of HA. The average crystal size of the nanoparticles calculated from the diffraction peak half-widths according to Scherrer's equation for the Fe_3O_4-HA in concentrations of 10-40 wt.% decreased from ~17 nm to ~10 nm, respectively. Moreover, Fe_3O_4 conjugation with humics lead to increase specific surface from 117 to 142 m^2/g for the Fe_3O_4 and the Fe_3O_4-HA20 accordingly. The sorbents under study are characterized by a high sorption capacity regarding to ciprofloxacin. The results obtained indicate that the adsorption of CIP by the Fe_3O_4-HA20 is largely enhanced in comparison with the bare Fe_3O_4. Acknowledgement. This research has been financed by the Russian Foundation for Basic Research (#18-44-920007 – synthesis and characterization of composites, and #18-33-00335 mol_? – investigations of CIP sorption).

MO017

Effect of sodium hexa-metaphosphate on soil hydraulic properties

P. Gautam, Kunsan National University; S. Jeong, Kunsan National University / Department of Environmental Engineering

In the field of soil remediation, removal of the contaminants largely depends on the soil permeability. Number of research have been conducted on infiltration and assisted remediation. Aggregation of the soil particle in the soil due to ionic attraction makes the soil less permeable for infiltration. However, very little action has been employed for the dispersion of the clay particle and assisted infiltration in the soil. This study would like to investigate different soil- hydraulic properties and associated infiltration of water in the partially saturated porous media with sodium hexa-metaphosphate (Na-HMP). Three solutions (water, 0.1% Na-HMP and 8.0% Na-HMP) were used for the premixing process. Soil was mixed with solutions and left overnight. Cumulative infiltration was recorded from a soil column equipped with the Marriott reservoir and mini disk infiltrometer. Significant difference was found for the test of infiltration and unsaturated hydraulic conductivity at a significance level of $\alpha = 0.05$. From the mean value comparison, differences was investigated for the soil treated with the water and Na-HMP. Highest difference was observed between 8% Na-HMP and water. With the addition of small concentration of Na- HMP, significant improvement in the soil-hydraulic properties was obtained. Improved soil-water property equipped with the infiltration using Na-HMP was due to the dispersion of the clay particle associated with high zeta potential and apparent reduction in the viscosity of the solution. Biogeochemistry and Fate of Organic Pollutants in Aquatic Systems (P)

MO018

Trends in mercury pollution levels of aquatic ecosystem components in the Republic of Uzbekistan

B. Karimov, Tashkent Institute of Irrigation and Agricultural Mechanization Engineers (TIIAME) / Ecosystem Services Conservation; D.A. Vignati, CNRS / LIEC UMR7360; M. Plotzen, Centre of hydrometeorological service of the republic of Uzbekistan; S. Polesello, Water Research Institute- CNR / Water Research Institute

Determination of total mercury in filtered water samples was conducted by cold-vapor atomic-absorption method. Mercury concentrations in samples of aquatic bottom sediments and fish muscle from Uzbekistan were determined in CNR-IRSA, Italy using atomic-absorption spectrometry (AMA 254). The analyses of mercury concentrations in river waters during 2004-2014 have revealed that, in most rivers, the concentration of mercury ranged between below detection limit (0.02 μg/L) and 0.35 μg/L which does not exceed all existing MPC for drinking water. However, these values exceeding MPC for natural waters established by EU directive 2013/39 (0.01 μg/L). Mercury concentrations found in some rivers such as Chirchiq, Akhangaran, Zarafshan, Syrdarya and Amankutansay, as well as canals (i.e. Salar, Bozsu and Siab), have reached 0.1 μg/L and even higher levels in some years. Concentrations higher than 0.1 μg/L can be considered as ecologically dangerous also due to possible analytical errors and increasing emissions. Concerning pollution sources as a rule, these rivers are situated in, or running through, industrialized and urbanized areas. Only two rivers may be considered as effected by transboundary pollution from neighbouring Kyrgyzstan and Tajikistan. Mercury concentrations detected in bottom sediments (maximum 26±2.8 μg/kg) and fish muscles (range 28-138 μg/kg) were much lower than MPL for soils – 2100 µg/kg and fish for human consumption (300 µg/kg). Levels in fish were however higher than the environmental quality standard of 20 μg/kg established by the European Union for the protection of aquatic wildlife against secondary poisoning of top predators such as aquatic birds and mammals. Based on conducted investigations it may be concluded that past and present environmental mercury pollution rates in Uzbekistan were within the permissible levels for human health (drinking water). However existence of possible dangerous impact of industrial and urban contamination on natural aquatic ecosystems reflected by elevated concentrations (higher than 0.1 μg/L Hg) indicates an urgent need to start future investigations in industrialised regions of the country and neighbouring Republics where large sources of mercury pollution exists.More extensive studies on Hg levels in fish and other organisms may be needed to understand if current Hg levels can pose a risk to top predators.

MO019

Water and sediment chemistry influences on mercury bioaccumulation in freshwater invertebrates from two lakes in Kejimkujik National Park, Nova Scotia

R. Clarke, Acadia University / Biology; N.K. Hillier, Acadia University / Department of Biology; S. Klapstein, Acadia University / Earth & Environmental Science; N. O'Driscoll, Acadia University / Department of Earth and Enviromental Science

Mercury is a trace metal and a toxic environmental pollutant that can be deposited in remote ecosystems and result in adverse effects on the heath of organisms. Elevated mercury levels at the bottom of the food web have implications for significant mercury (in the form of methylmercury (MeHg)) transfer to higher trophic organisms. Kejimkujik National Park (KNP), Nova Scotia is an area with a high landscape sensitivity to interactions with mercury. MeHg bioaccumulation in KNP lakes is of high concern in the area because elevated MeHg near the bottom of the food chain, such as near-sediment invertebrates, has implications for significant mercury transfer to higher trophic levels. Therefore, analysis of MeHg concentration in aquatic invertebrates and the relationship with water and sediment characteristics is required to understand food web bioaccumulation and relative bioaccumulation between invertebrates. Mayfly naiads, caddisfly larvae, lake water, and benthic sediments were collected from two lakes and one wetland catchment in KNP. Methylmercury (MeHg) was analyzed in all samples using gas chromatography-atomic fluorescence spectroscopy (AFS). MeHg concentrations in mayflies and caddisflies ranged from 14.28–427.78 ng/g (N=58), 0.05–0.46 ng/L (N=45) in water, and 0.02–28.94 ng/g (N=22) in sediment. It was found that mayfly MeHg concentration was positively correlated with water MeHg concentration (Spearman Rank correlation coefficient (r_s)=0.43; P-value=0.02). Caddisflies may be more associated with sediment MeHg concentration than water MeHg (r_s=0.45;0.07, respectively), although correlations were not significant. Most sediment and invertebrate samples and all water samples from the wetland catchment were significantly higher in MeHg concentration than the lake locations because wetlands are areas of efficient MeHg production. In conclusion, no significant relationships were observed between MeHg concentration in caddisfly and mayfly and sediment MeHg. However, our data do suggest that mayfly MeHg concentration is influenced by water characteristics (MeHg, pH). Analysis of MeHg bioaccumulation in aquatic invertebrates and the relationships with water and sediment characteristics are key. More research into MeHg bioaccumulation is necessary to better understand food web transfer.

MO020

Using laboratory incubations to predict the fate of pharmaceuticals in aquatic ecosystems

J. Fahlman, Umeå Universitet / EMG

Environmental persistence is a key property when evaluating risks with excreted pharmaceuticals in aquatic ecosystems. Such persistence is typically predicted using small-scale laboratory incubations, but variation in aquatic environments and scarcity of field studies verifying laboratory-based persistence estimates create uncertainties around the predictive power of these incubations. In this study we: i) assess persistence of five pharmaceuticals (diclofenac, diphenhydramine, hydroxyzine, trimethoprim and oxazepam) in laboratory experiments under different environmental conditions; and ii) use a three-month long field study in an aquatic ecosystem to verify the laboratory-based persistence estimates. In our laboratory assays, we found that water temperature (TEMP), concentrations of organic solutes (TOC), sediment presence (SED), and solar radiation (SOL) individually affected dissipation rates. Moreover, we identified rarely studied interaction effects between the treatments (i.e. SOL x SED and TEMP x SOL), which affected persistence of the studied drugs. Half-lives obtained from the laboratory assays largely explained dissipation rates during the first week of the field study. Yet, none of the applied models did accurately predict long-term dissipation rates (monthly time-scale) from the water column. For example, the studied antibioticum (trimethoprim) and the anti-anxiety drug (oxazepam) remained at detectable levels in the aquatic environment long after (~150 days) our laboratory based models predicted complete dissipation. We conclude that small-scale laboratory incubations seem sufficient to approximate short-term (i.e. within a week) dissipation rate of drugs in aquatic ecosystems. Yet, this simplistic approach does not capture interacting environmental processes that preserve a fraction of dissolved pharmaceuticals for months in natural water bodies.

MO021

Occurrence of Pharmaceutical and Personal Care Products in Wild Fish Plasma in Taihu Lake and Application of the Fish Plasma Model

Y. Bao, Y. Liu, J. Hu, X. Hu, Tongji University; D. Yin, Tongji University / College of Environmental Science and Engineering

Pharmaceuticals and personal care products (PPCPs) are a class of emerging contaminants and occur widely in aquatic environment at low concentrations ranging from ng/L~µg/L. Long-term exposure to low concentration of PPCPs may pose potential toxicity to fish as well as other aquatic organism, thus harm to aquatic ecosystem. Analysis of plasma concentration of PPCPs in wild fish which is the typical spinal aquatic organism is of great significance. The Fish Plasma Model use the drug concentration in fish plasma to estimate the ecological risk of the pharmaceuticals to aquatic organisms. However, the existing fish Plasma model(log $P_{\text{Blood: Water}}$=0.73×Log K_{OW}-0.88) is not yet perfect, which is mainly comfit for hydrophobic substances. Taihu basin is located in the Yangtze River Delta economic zone in China. The industrial production and population density in Taihu basin is so high that the production and consumption of PPCPs in this area account for the high proportion of the whole country. Typical wild fish include crucian carp, bighead carp, silver carp, common carp, surf fish, carassius auratus and hemiculter clupeoides in Taihu Lake were study from 2015 to 2017, and their plasma samples were analyzed for 29 PPCPs. In general, the detection concentration of PPCPs in the plasma of wild fish was higher than that in the environment, ranging from 0.13 to 2824.21 ug/L. In three years, 25 kinds of PPCPs were detected in all fish plasma except ENR, CTC, SMZ and GFZ. From the distribution of fish species, crucian carp had the highest plasma concentration, followed by bighead carp, silver carp and common carp. The concentration of PAR in plasma was the highest, ranging from 2.17 to 717.03 ug/L. Because of the large difference between K_{ow} and D_{ow} of most substances, the original fish plasma model can not be directly applied to all drugs. For improvement, we replace K_{OW} with D_{OW}, introduce the half-life of the drug, classify the drugs according to different drugs or different properties to obtained a better fitting formula (log $P_{\text{Blood: Water}}$ = a + b × log D_{OW} + c×exp(d×t1/2)). Based on the improved fish plamsa model, the trend of BAF in measured fish plasma is the same as that in predicted $P_{\text{Blood: Water}}$. The predicted steady plasma concentration in fish is generally lower than the measured value, which indicates that the ecological risk calculated by the formula is seriously underestimated.

MO022

Impacts of Bacterial Diversity and Hyporheic Exchange Flows on the Fate of Wastewater-derived Polar Organic Micropollutants - A Central Composite Face Designed Flume Study

M. Posselt, Stockholm University / Department of Environmental Science and Analytical Chemistry; C. Coll Mora, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; J. Mechelke, Eawag Swiss Federal Institute of Aquatic Science and Technology; A. Jaeger, Leibniz-Institute of Freshwater Ecology and Inland Fisheries IGB; C. Rutere, University of Bayreuth; M. Raza, IWW Water Centre; A. Betterle, Eawag Swiss Federal Institute of Aquatic Science and Technology; T. Singh, University of Birmingham; S. Krause, University of Birmingham / The School of Geography Earth and Environmental Sciences; J. Hollender, Eawag / Environmental Chemistry; A. Sobek, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; J. Lewandowski, Leibniz-Institute of Freshwater Ecology and Inland Fisheries IGB; M.A. Horn, University of Hannover; K. Meinikmann, Leibniz-Institute of Freshwater Ecology and Inland Fisheries IGB; J.P. Benskin, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

The combined effects of bacterial diversity and hyporheic exchange flows on the fate of 30 polar organic micropollutants were investigated in 24 recirculating flumes using a fractional factorial design. The 2 meter long sediment and water filled outdoor flumes were sheltered from precipitation and direct radiative forcing to control water and energy in- and outputs. Polar organic micropollutants were fortified at 10 μg/L each, and surface water and pore water concentrations were tracked over 78 days. Bacterial diversity (low, medium, or high) was adjusted by diluting sediments from a wastewater-impacted stream, while different intensities of hyporheic exchange flows (low, medium, or high) were obtained by adjusting the number of bedforms of the flume sediments. Nutrient concentrations, pH, dissolved oxygen profiles, solar radiation, water level, bacterial diversity, and temperature were monitored throughout the course of the experiment. Each combination of variables (i.e. bacterial diversity and hyporheic exchange flow) was replicated once for model development, after which validation of the model was carried out using n=4 mid-point experiments. Two non-inoculated and two non-spiked controls were included to quantify abiotic losses and background contamination, respectively. Dissipation half-lives (DT50s) were fitted to a response surface model of the parameters bacterial diversity and hyporheic exchange flow. Our initial hypothesis was that increased bacterial diversity and hyporheic exchange flow would result in a decrease in DT50s. However, while DT50s of almost all compounds decreased with increasing bacterial diversity, the effect of bedform-induced hyporheic exchange was less marked. Pharmaceuticals such as valsartan, propranolol or sotalol seemed more stable in flumes with a high number of bedforms. The fate of the anti-diabetic drug metformin was unaffected by altered hyporheic flow but was almost fully transformed to guanylurea and partially further degraded within 28-42 days in flumes with high bacterial diversity. A number of transformation products such as metoprolol acid, carbamazepine-10,11-epoxide and valsartan acid originating from other parent compounds were also detected. This study provides evidence that hyporheic exchange flow and especially bacterial diversity are important factors of polar organic micropollutant degradation in stream systems.

MO023

Metabolites & transformation products of medicinal products - are they of environmental relevance?

D. Gildemeister, Umweltbundesamt / German Environment Agency / IV2.2 Pharmceuticals; S. Zahorszki, German Environment Agency UBA / IV Pharmaceuticals; I. Rönnefahrt, German Environment Agency - UBA / Section IV 2.2 Pharmaceuticals

Pharmaceuticals administered to the patient, be it human or animal, are metabolised in the body and are excreted as parent compound and/or metabolites. Hence, in contrast to other substance classes, pharmaceuticals enter the environment almost entirely as a mixture of parent and metabolites and may be further transformed during activated sludge treatment in sewage treatment plants and/or in the receiving environmental compartments. However, in existing risk assessment concepts, the estimation of the predicted environmental concentration (PEC) is primarily based on the so-called total residue approach, i.e., metabolism in patients is not taken into account. The basic idea of this concept is that it is assumed that neither metabolites nor transformation products have a greater impact on the environment than the parent compound. However, it remains debatable whether this approach is valid. For instance, the fact that individual excreted metabolites or resulting transformation products may be more hydrophilic than the parent compound and hence may be more mobile and/or more persistent in the environment needs to be considered e.g. with respect to groundwater protection. In such cases, metabolites and/or transformation products might be even more relevant than the parent compounds. Based on long-term experiences in environmental risk assessment within the authorisation procedure of human medicinal products the poster will present insights on fate and potential environmental impact of metabolites and transformation products of active pharmaceutical substances. According to the ‘Guideline on the environmental risk assessment of medicinal products for human use’ (EMEA/CHMP/SWP/4447/00, corr. 2) the fate of an active substance in the environment is described with a study on adsorption /desorption (OECD 106, Koc), a study on ready biodegradability (OECD 301) and a water-sediment simulation test (OECD 308). Furthermore, for some substances with a Koc-value > 10.000 also a study on aerobic transformation in soil (OECD 307) should be available. Based on these scientific findings the poster provides a critical reflection on the relevance of metabolites and transformation products of medicinal products in the light of current risk assessment strategies.

MO024

Effects of antibiotic residues on the growth and photosystem II efficiency in baltic cyanobacteria

K. Pazdro, Institute of Oceanology, Polish Academy of Sciences / Department of Marine Chemistry and Biochemistry; g. siedlewicz, l. sharma, Institute of Oceanology Polish Academy of Sciences; a. zak, university of gdansk; A. Kosakowska, Institute of Oceanology Polish Academy of Sciences / Department of Marine Chemistry and Biochemistry

The aim of the study was to measure the influence of selected antibiotics, most often detected in the Baltic Sea, on the growth and photosystem II of non-target organisms - cyanobacteria *Microcystis aeruginosa* and *Nodularia spumigena* and the model organism *Chlorella vulgaris* by using longer lasting tests (11 days). Standard measurements (cell number, optical density, chlorophyll *a* concentration) were combined with OJIP fluorescence transitions measurements. The obtained results showed that low, theoretically safe levels of antibiotics residues can have negative impact on the tested microorganisms. Oxytetracycline caused decrease of photosystem II efficiency and showed the potential to disrupt photosynthesis process

MO025

MICROBIAL RESPONSES TO ANTHROPOGENIC DISSOLVED ORGANIC CARBON IN ARCTIC AND ANTARCTIC COASTAL SEAWATERS

E. Cerro-Gálvez, Institute of Environmental Assessment and Water Research; D. Lundin, Linnaeus University; P. Casal, Institute of Environmental Assessment and Water Research IDAEACSIC; B. Pina, IDAEA-CSIC / Department of Environmental Chemistry; J. Pinhassi, Linneaus University; J. Dachs, IDAEA-CSIC / Environmental Chemistry; m. vila-costa, Institute of Environmental Assessment and Water Research IDAEACSIC

Thousands of semi-volatile hydrophobic organic pollutants (OPs) reach open oceans through atmospheric deposition causing a chronic and ubiquitous pollution by anthropogenic dissolved organic carbon (ADOC). Besides be prone to biodegradation, these compounds accumulate in cellular lipids, inducing harmful effects on marine biota. Unfortunately, their possible effects on microorganisms, key drivers of global biogeochemical cycles, remain unknown. We challenged coastal microbial communities from Ny-Ålesund (Svalbard, Arctic) and Livingston Island (South Shetlands, Antarctica) with ADOC amounts within the range of oceanic concentrations in 24 hours incubations to investigate this largely uncharacterized vector of global change. ADOC addition elicited clear transcriptional responses in multiple microbial heterotrophic activities in ubiquitous groups such as Flavobacteriia, Gammaproteobacteria and SAR11. Importantly, a suite of cellular adaptations and detoxifying mechanisms, including remodeling of membrane lipids and transporters, was detected. ADOC exposure also changed the composition of microbial communities, in particular by the increased number of 58 taxa in Arctic and 34 taxa in Antarctica from the rare biosphere. Many of these taxa belong to described OP-degrading bacteria and showed the most different gene expression profiles between ADOC amendments and controls among all groups. This work shows that ADOC at environmentally relevant concentrations substantially influence the marine microbial communities.

MO026

Measuring aerobic biodegradation kinetics of organic micropollutants in-situ

M. Goss, Stockholm University, ACES / Department of Environmental Science and Analytical Chemistry ACES; Z. Li, Stockholm University / ACES; M. McLachlan, Stockholm University / Environmental Science and Analytical Chemistry (ACES)

Accurate assessment of the biodegradation kinetics of organic micropollutants is essential to characterize their behavior and persistence in the environment. The OECD 309 test for the assessment of aerobic mineralization of organic micropollutants such as pharmaceuticals in surface waters has shortfalls that reduce its environmental relevance. Studies have shown that the concentration of spiked analytes, often well above environmental concentrations in tests, significantly affects the observed biodegradation rates. Likewise, spiked samples typically exhibit a lag phase, during which the microbial population undergoes adaptation, departing from steady-state natural conditions. Targeted analysis of spiked samples limits the range of chemicals tested and the requirement of a laboratory environment limits the range of water sample locations, and hence the range of microbial populations. A prior study has demonstrated that biodegradation can be measured in unspiked natural water samples. To further increase the environmental relevance of these tests, we again use unspiked natural water but instead perform the kinetics study in-situ. By suspending amber glass bottles as our test chambers in a river downstream of a wastewater treatment plant, we parallel the natural system more closely than a lab test and simultaneously reduce the resources necessary, enabling these tests to be carried out in more remote areas. We compare our results to those of an unspiked laboratory biodegradation test, using non-target high resolution mass spectrometry to quantify biodegradation kinetics for a broader range of micropollutants.

MO027

Influence of sediment bacterial community composition on biotransformation of organic micropollutants

C. Coll Mora, Stockholm University / Environmental Sciences and Analytical Chemistry; Z. Li, Stockholm University / ACES; R. Bier, S. Langenheder, Uppsala University / Department of Ecology and Genetics/Limnology; E. Gorokhova, Stockholm University / Department of Environmental Science and Analytical Chemistry (ACES); A. Sobek, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

Biodegradation is an important removal mechanism of micropollutants in aquatic ecosystems and comprises multiple processes which are performed primarily by bacteria. To assess biodegradation in water-sediment systems, the OECD308 standard test is often used. For this study we hypothesize that different sediment substrates may contain different bacteria communities and its composition can influence the degradation of micropollutants. We performed bottle incubations of ten micropollutants: acetaminophen (ACT), acesulfame K (ACK), caffeine (CAF), carbamazepine (CBZ), diclofenac (DIC), furosemide (FUR), metformin (MET), oxazepam (OXZ), tramadol (TRM) and venlafaxine (VFX) according to the OECD308 standard using sediment from rivers Fyris (F), Sweden and Gründlach (G), Germany, before (1) and after (2) the discharge of a local waste water treatment plant (WWTP). The dissipation half-lives (DT50s) were calculated assuming first order kinetics. Illumina sequences of bacterial 16S rRNA were used to analyse the bacterial community composition in the sediment at the end of the incubation. The DT50s obtained for five micropollutants (CBZ, OXZ, TRM, VFX and ACK) have significant differences (p-values ≤ 0.05) between the two rivers and locations to the WWTP, DIC presented differences between rivers and FUR between locations. Except for ACK, longer DT50s were observed at location G2 than in any other treatment, and shorter in G1 and F1. The analysis of sequences indicate that there are no significant differences in the structure of the bacterial communities in sediment from F, but that the two locations in river G are significantly different from F (p-value ≤ 0.001) and each other (p-value ≤ 0.001). Differential abundance analysis for DT50s of CBZ, VFX and TRM, show that 58 bacteria genera are significantly more abundant in the samples where fast degradation was observed and could be associated with this response. Slow degradation was associated with 32 bacteria genera for the same four compounds. Different genera were significant for the differences in fast or slow degradation of OXZ, DIC and ACK. Random forest discriminant analysis as well as partial least square discriminant analysis were also performed for comparison. This study shows that bacteria community composition can influence the observed degradation of micropollutants in OECD308 test and that specific bacteria consortia might be associated with fast or slow degradation.

MO028

The Biodegradability of Acetaminophen using Multiple OECD 301 Guidelines and the OECD 307 Guideline

S.P. McLaughlin, Smithers Viscient, LLC / FATE; D. Koch, Smithers Viscient; R. Brackett, K. Malekani, Smithers Viscient / Environmental Fate and Metabolism

The ready biodegradability of Acetaminophen is assessed in this study based on several OECD 301 Guidelines and its biodegradability in the natural environment is determined using a simulation test based on the OECD 307 soil metabolism guideline. Several studies are publicly available that show Acetaminophen being biodegradable in activated sludge. However, most of these studies do not follow the strict requirements of the OECD 301 Ready Biodegradability Guidelines. This study aims to determine if Acetaminophen can pass a Ready Biodegradability Test and if the results are repeatable using several different test designs permitted by the OECD 301 Guidelines. The exact OECD guidelines followed were the OECD 301B, OECD 301F and OECD 310 Guidelines. The ready biodegradability results for Acetaminophen, based on CO_2 evolution, obtained in the OECD 301B portion of the study and average CO_2 evolution results obtained in the soil metabolism study using two soils are presented below: **Ready Biodegradation, %** Days 1 2 5 9 16 28 Acetaminophen 0.4 -1.0 45.7 61.9 70.5 67.5 **CO_2 Evolution from Soil, %AR** Days 4 15 33 64 123 Acetaminophen 13.0 16.3 19.8 23.5 26.5 Results from additional tests, using the other 301 guidelines, will be presented and compared to the OECD 301B results. Reasons for the differences of the CO_2 evolution results between the 301 studies and the soil simulation test, will be discussed in relationship to non-extractable and bound residues. The use of Acetaminophen as a potential reference compound will also be evaluated.

MO029

Transformation of organic chemicals in aquatic sediment systems (OECD 308) under simulated natural sunlight

S. Hoeger, Innovative Environmental Services IES Ltd / Environmental Toxicology; C. Wijntjes, Innovative Environmental Services (IES) Ltd / Environmental Fate; D. Adam, W. Völkel, Innovative Environmental Services IES Ltd / Environmental Fate

Chemicals that are directly applied to surface water or that are likely to reach the aqueous environment by routes such as run-off, drift and agricultural effluents, are required to pass environmental risk assessments. As an essential part of tiered testing strategies, the OECD 308 Guideline defines laboratory testing to assess aerobic and anaerobic transformation of organic chemicals in aquatic sediment systems in the dark. In order to further simulate environmental conditions, and ascertain half-lives or disappearance times (DT50, DT75, DT90) for test compounds while being exposed to irradiation, requests for including natural sunlight and/or Algae in OECD 308 study designs have been emerging. Innovative Environmental Services (IES) Ltd, Switzerland, as an independent GLP-certified contract research organization, brings ten years of experience with aerobic aquatic sediment studies under simulated natural sunlight conditions, performed for a variety of recurring clients. The laboratory set-up used by IES Ltd for irradiated OECD 308 studies, with and without Algae, will be elaborated upon in detail, and potential advantages and disadvantages of including simulated natural sunlight in the test design will be explained. In addition, the need for a new or adapted test guideline will be discussed.

MO030

Natural Bromoanisoles in Northern Baltic Estuaries

T.F. Bidleman, Umea University / Department of Chemistry; A. Andersson, Umea University / Department of Ecology and Environmental Sciences; S. Brugel, Umea University / Dept. of Ecology and Environmental Sciences; P. Haglund, Umea University / Department of Chemistry; O. Nygren, Umea University / Faculty of Medicine, Deans Office; M. Tysklind, Umea University / Department of Chemistry

Bromoanisoles (BAs) are O-methylation products of bromophenols (BPs), which are produced by many species of marine macroalgae [1] and cyanobacteria [2]. BAs evaporate from the sea [3] and are transported long distances through the atmosphere [4]. BAs and BPs bioaccumulate, from macroalgae to grazing amphipods to fish [5]. In our investigations of macroalgae as a source of BAs to Baltic ecosystems [1], we measured BAs in seawater of four estuaries and at two offshore stations in the northern Bothnian Sea (northern Baltic) at monthly intervals during spring-summer, 2018: late May-early June, mid-July and mid-August. Only 2,4-DiBA and 2,4,6-TriBA were found; those with meta-Br substitutions were absent. Over all months, the concentrations of 2,4-DiBA (63-457 pg L^{-1}) and 2,4,6-TriBA (157-768 pg L^{-1}) were higher in estuaries than offshore (43-78 and 86-143 pg L^{-1}, respectively) Monthly variations in the estuaries were strikingly different for the two compounds: 2,4-DiBA peaked in mid-July, with lower concentrations in May-June and mid-August, while 2,4,6-TriBA was highest in May-June and declined over the summer. Offshore trends mirrored those in estuaries, but with lower amplitude. Similar concentrations were observed in August at the island Holmön, where 2,4-DiBA and 2,4,6-TriBA were 340 and 400 pg L^{-1} in a shallow strait with visible macrophytes versus 53 and 102 pg L^{-1} at an offshore station. Concentrations and monthly variations of the two BAs are likely due to differences in macrophyte and/or cyanobacteria populations, rates of O-methylation which converts BPs to BAs, and to estuarine-offshore water mixing. MO031

Compounds of emerging concern in a changing climate: the case of 1,4-Dioxane

M.H. Wagelmans, Rijkswaterstaat / WMCN

Compounds of emerging concern are entering the aquatic system via various routes and are being discharged by streams and rivers eventually ending up in the ocean. At the same time we are facing the effects of climate change. Due to climate change long periods of drought can occur. This affects the water discharge and as a result also the water quality of rivers. The Netherlands, as the rest of Western Europe, have faced extreme drought in 2018. The water discharge of our rivers was historically low. In September 2018 upstream in the river Rhine 1,4-Dioxane was discharged in amongst others a small river entering the river Rhine. This had led to an exceedance of the alarm values for this compound at the monitoring stations. When a compound is found at a level above the alarm value, in this case 3 μg/l, a model is run to predict when the compound might reach the drinking water intake point. Usually this is within a couple of days. However in this case the discharge of the river was historically low whereby the model was unable to correctly predict the time at which the water intake points would be reached. Calculations had to be made by hand. Because of the low discharge the compound remained in the system much longer than during average discharge which might cause negative effects to the aquatic ecosystem. Drinking water companies producing drinking water from river water were alarmed and had to request for a temporary dispensation for water intake for a long period of time. That means that the can continue to produce drinking water even though the concentration of a compound, in this case 1,4-Dioxane, is slightly above their guideline value (1 μg/l for this compound). Continuous updates of the concentrations of 1,4-Dioxane were provided to drinking water companies. The monitoring program for 1,4-Dioxane was extended further downstream in the river and the Amsterdam-Rhine channel where concentrations were measured three times per week during a period of at least six weeks. The poster will highlight the concentrations of 1,4-Dioxane in time and space. Furthermore the concentrations will be related to river discharge. It is expected that in our changing climate we will be facing low river discharge more often. This means that in the future we will have to adjust the models to be able to adequately predict when compounds that exceed alarm values will reach the drinking water intake points.

MO032

Brominated flame retardants at the snow, seawater and plankton collected at the Antarctic Peninsula

A. Cabrerizo, P. Casal, Institute of Environmental Assessment and Water Research IDAEACSIC; G. Casas, J. Dachs, IDAEA-CSIC / Environmental Chemistry

Concurrent sampling of seawater, snow and plankton for a range of recently regulated brominated flame retardants (BFRs), such as PBDEs, non-BDE flame retardants such as dechloranes (plus and anti isomers) and hexabromocyclododecane (α-HBCDD) were undertaken at coastal areas of Livingston Island (Antarctica). Sampling were performed during three months, covering late spring (December 2014) to late summer (February 2015) in order to assess for the first time the presence of these chemicals in the area. For seawater and plankton sampling, two locations were selected, one close to a glacier, which gives potential inputs of snow/ice to the ocean and therefore of pollutants and a second site located away from the glacier. Overall, all BFRs were detected in all the selected matrices. ΣPBDE concentrations (sum of 46 congeners, excluding BDE209) in plankton were in the range of 23-215 ng/gdw in samples collected away from the glacier. Slightly higher ΣPBDE were found in those samples collected at the glacier, with Σ_{46}PBDE concentration in the range of 32-314 ng/gdw. BDE-47 and -99 were the predominant congeners quantified in plankton samples. Overall, slightly higher concentrations of individual PBDEs (e.g 47, 99, 100, 153) were found in plankton collected close to the glacier in comparison to those samples collected far away from it, which may suggest that the melting of the glacier may be impacting the lower levels of the Antarctic food web. On the other hand, the most frequently detected non-PBDE flame retardants were dechloranes (plus and anti isomers).Dechlorane plus and anti were found in 100% of the samples analyzed for this chemical), while α-HBCDD were found in the 67% of the samples analysed. However, no differences were found in plankton collected at both selected locations.

MO033

Analysis method development of organophosphate using liquid chromatography-tandem mass spectrometry in Great Lake fish

Y. Choi, Gwangju Institute of Science and Technology; C. Hao, D. Morse, Ontario Ministry of the Environment Climate Change / Laboratory Services Branch; S. Kim, Gwangju Institute of Science & Technology / School of Earth Science and Environmental Engineering

Flame retardants are chemicals that inhibit combustion and are added to products such as plastics, textiles and electronics. Previously used brominated flame retardants were phased out because of adverse effects in environment and health impacts on human, and replaced to alternative chemicals, such as organophosphate flame retardants (OPFRs). They are widely used for textile manufacture as easy to handle and are cost effective to recycling the products. In spite of large chemical usage, analysis information for organophosphate is insufficient. Effective analysis for OPFRs were developed to apply for Great Lake fish using liquid chromatography-tandem mass spectrometry (LC-MSMS). Twenty-two OPFRs were exposed in fish samples, *Oncorhynchus mykiss* and *Menticirrhus saxatilis*. Prepare homogenized fish samples, solvent mixture (methanol, water and formic acid) shake with fish samples. In this study, extraction steps were simplified in order to minimize chemical loss. LC-MSMS analysis method not only increased intensity of individual organophosphate chemicals, but also separated isomers well. The average recoveries were 69-140% in *Oncorhynchus mykiss* and 71-132% in *Menticirrhus saxatilis*, and limits of quantitation (LOQs) were 0.03-0.44ug/L and 0.01-0.76ug/L, respectively. Developed method were applied for fish samples in Lake Ontario, Canada and EHDP, TBEP, TCPP, TCEP and TOTP were mainly detected.

MO034

Can forest fires be a diffuse source of contaminants (PAHs) to the aquatic system?

I. Campos, Universidade de Aveiro / Department of Environment Centre for Environmental and Marine Studies CESAM; J.J. Keizer, University of Aveiro / Department of Environment and CESAM; P. Pereira, University of Aveiro / Department of Biology and CESAM; N. Abrantes, University of Aveiro-CESAM / CESAM/DAO

Polycyclic aromatic hydrocarbons (PAHs) are widespread environmental contaminants, which have been raising important health and environmental concerns due to their toxic, carcinogenic, mutagenic and teratogenic properties. Additionally, they show a high environmental persistence and bioaccumulation potential, being some of them listed as priority pollutants by the United States Environmental Protection Agency (USEPA) and the European Commission (EC). Forest fires have been identified as an important source of PAHs in the environment. For instance, these contaminants could be mobilise during a wildfire from ashes and sediments loads and may eventually reach the nearby aquatic systems by surface runoff. These detrimental off-site effects are particularly notorious during the initial post-fire period, although not necessary limited to it. Hence, the present study aimed to assess the effects of wildfires on PAHs contamination of water resources. To this end, five campaigns, following a wildfire in north-central Portugal and during eighteen months, were performed to assess the temporal trends and profiles of the fifteen priority PAHs (by USEPA) in samples of surface runoff collected in an unburnt and burnt eucalypt plantations, as well as a nearby downstream. The principal results obtained in this study were the following: (1) immediately after the fire, the total sum of the PAHs was 4-fold higher in the burnt surface runoff than in the unburnt runoff, while the stream presented higher levels than the unburnt runoff; (2) The concentrations of the PAHs decreased gradually and approach the background levels eighteen after the fire; (3) The levels of light PAHs with three to four rings were at higher levels than heavy PAHs with five to six rings, thus showing a similar profile between the water samples; (4) in terms of individual PAHs, the unburnt runoff was dominated by the anthracene while the burnt runoff and stream water were dominated by the phenanthrene. The present study clearly demonstrated the effects of wildfires on PAHs mobilisation by overland flow and thus pointed towards recently burnt forest areas as a potential source of diffuse environmental contamination of aquatic ecosystems. This information is of crucial importance to predict the risks and effects of the surface water contamination by recently burnt areas and increasing knowledge on water quality alterations due to forest fires.

MO035

Polycyclic aromatic hydrocarbons (PAHs) in cores from the depth part of the Gulf of Mexico: an interpretation

M. Casillas, Universidad Autonoma de Baja California; J. Macias-Zamora, Universidad Autonoma de Baja California / Institute of Investigation Oceanologicas; C. Quezada, Universidad Autonoma de Baja California

The Gulf of Mexico is the largest marginal se along the atlantic in the american continent. It is very important sea because of its large biodiversity and also because of its large economic contribution to both US and Mexico due to its oil deposits. It has become one of the most studied semienclosed seas after two of the largest oil spills occurred in this Gulf, the second largest the Ixtoc spill that occured in 1979 and the largest one, more recent the Macondo well which occurred in 2010 from the Deepwater Horizon (DWH) platform. It has been also registered that there are many natural filtration of oil in this part of the world oceans. There is renewed interest for understanding the functioning of the Gulf, the circulation, largely dominated by the Loop Current due to the latest spill, in particular to determine if a portion of the spilled oil reached mexican waters and sediments. Because of importance of polycyclic aromatic hydrocarbons as a relatively large component of crude oil and specially due to its larger resistance to degradation, we decided to investigate the characteristics of these compounds in several deep cores strategically located in the area of the Gulf. The importance of these chemicals is; in addition to its toxicity, their potential to help in explaining their origin using some ratios and mixed plots. This region receives a large amount of hydrocarbons, including potentially toxic polycyclic aromatic hydrocarbons (PAHs) from a several sources; river discharges, coastal erosion, atmospheric deposition, natural oil seeps, and accidental oil leaks related to petroleum exploration/transportation. The PAHs have relatively low aqueous solubility get readily sorbed onto soil and sediments, and eventually deposited to the seafloor. The seafloor sediments are considered to be the long term repository of PAHs and the deep-sea sediments are therefore the major global sink for PAHs entering into ocean waters. Two cores located in opposite zone were analyzed, one is located at the center of the Gulf of Mexico (core A5) with depth of 3,515m and a second one is located south of the Gulf of Mexico (core G44) in front of the mexican states of Tabasco and Campeche located near the oil maritime platform (Campeche Shelf) at a depth of 2,354m. Result indicate that the concentrations of ∑PAHs vary between 95 and 155. ng/g and 73.78 and 537.23 ng g-1, respectively.

MO036

Influence of stereochemistry on the partitioning of selected ortho and non-ortho polychlorinated biphenyls between aqueous solution and soil system.

G.C. Adeyinka, University of KwaZulu-Natal / Chemistry

The influence of sorbate characteristics such as stereochemistry on the partitioning of selected non-ortho and ortho-substituted polychlorinated biphenyls (PCBs) between aqueous solution and soil collected along the river course of uMngeni River of KwaZulu-Natal, South Africa located in sub-Sahara Africa was investigated in this study. Specifically, PCB 77 and PCB 52 were selected in this study to represent the non-ortho and ortho-substituted system. These congeners were chosen due to their historical environmental problems and varying degree of hydrophobicity characters despite their equal numbers of chlorine atoms. Soil physicochemical characteristics were quantified such as soil organic matter, cation exchange capacity, surface area, pore volume distribution, and pore diameter as well as various functional groups present in the soil humic materials using Walkley Black, BET adsorption-desorption, and FTIR methods respectively. Batch adsorption experiments were used for the sorption studies. The results of the investigation revealed that non-ortho substituted congener was found to show more preference for soil compared to its di-ortho substituted counterpart congener of the same homolog. The effect of initial concentrations on both revealed that low initial PCB concentrations were mostly favoured for the sorption while sorption was generally low for ortho-substituted PCBs at high concentration. This could be due to the soil interlayer pore blockage which may be influenced by the position of the chlorine. Also, non-ortho PCB 77 was said to be more hydrophobic due to the orientation of chlorine atoms which allows for the free rotation of chlorine atoms between the phenyl rings and practically impossible in PCB 52 thereby making it more susceptible to aqueous solubility. Due to the susceptibility of ortho-substituted congeners to aqueous solubility, it is, therefore, more likely for this pollutant to re-suspended back to surface water or leach to the groundwater more easily when sorbed by soil and may possibly pose more risk to the aquatic ecosystem relative to its non-ortho substituted congener of the same homolog. However, PCB 77 are more likely to result in steady sorption by soil and become less available to the aquatic life which may then become more available to filter feeder organisms who source their food from surface sediment.

MO037

Diffusive air-water exchanges of Polycyclic Aromatic Hydrocarbons in an

oligotrophic North Patagonian lake from Chile

F. Tucca, T. Luarte, Universidad Andrés Bello / Department of Ecology and Biodiversity; J. Nimptsch, S. Woelfl, Universidad Austral de Chile / Instituto de Ciencias Marinas y Limnologicas; J. Dachs, IDAEA-CSIC / Environmental Chemistry; C. Galban-Malagon, Universidad Andrés Bello / Departamento de Ecología y Biodiversidad

Polycyclic Aromatic Hydrocarbons (PAHs) are semivolatile organic pollutants of concern because of their ubiquitous occurrence, bioaccumulation potential and toxic effects on ecosystems and human health. This study aim is to know the influence of local sources of anthropogenic PAHs (i.e., agricultural waste burning, indoor firewood burn and vehicular emission) on the air-water exchange in an oligotrophic north Patagonian lake of Chile. The monitoring was carried out in Panguipulli Lake (Los Ríos Region, Valdivia, Chile) during autumn-winter seasons (year 2017) due to higher possibility of PAHs emissions by incomplete combustion of organic materials released from surrounding areas. PAHs such as Methylnaphthalene (Mnap), Acenaphthylene (Acy), Acenaphthene (Ace), Fluorene (Fluo), Trimethylnaphthalene (Tnap), Phenanthrene (Phe), Anthracene (Ant), Methylphenanthrene (Mphe), Pyrene (Pyr), Chrysene (Chry), Benzo[b&k]fluoranthene (BbkF), Benzo[a]pyrene (BaP), Perylene (Per), Dibenz[a,h]anthracene (DBA), Coronene (Cor) were quantified in surface water and air matrices through GC-MS. To determine the freely dissolved concentration in water measured concentrations were corrected by dissolved organic carbon (DOC) for each sampling period. For understanding the short-term dynamic between water and air the fugacity ratios ($fw\,fa^{-1}$) for every day were calculated. Panguipulli Lake reported the occurrence of 15 PAHs in air (mean $\sum_{15}$PAHs= 11615 pg m^{-3}) and water (mean $\sum_{15}$PAHs= 961 pg L^{-1}), where the higher concentrations in the environment were quantified for Mphe (air_{max}: 8460 pg m^{-3}; $water_{max}$: 707 pg L^{-1}) and Pyr (air_{max}: 30533 pg m^{-3}; $water_{max}$: 2296 pg L^{-1}). Air-water diffusive exchanges of PAHs showed a tendency from a net volatilization ($\log fw\,fa^{-1} > 0.5$) for less hydrophobic ($\log K_{OW} < 4$) and lighter PAHs (i.e., Mnap, Acy, Ace, Fluo, Tnap) to net deposition ($\log fw\,fa^{-1} < -0.5$) for more hydrophobic ($\log K_{OW}$ 4 – 7) and heavier PAHs (i.e, Phe, Ant, Mphe, Pyr, Chry, BbkF, BaP, Per, DBA and Cor). A significant correlation was determined between log fugacity ratios and log K_{OW}s of PAHs (R-squared: 0.17; $p < 0.001$). This behavior of PAHs could suggest that the oligotrophic lake acts as a sink of organic pollutants derived from anthropogenic sources during autumn and winter seasons (pyrogenic source: Ant/Ant+Phe; petroleum and coal combustion: Fluo/Fluo+Pyr), being the heavier and more hydrophobic PAHs potential to reach bottom sediment. This study is a first approach to understand the source and diffusive transport of PAHs on oligotrophic lakes of the southern Chile. Acknowledgments to the FONDECYT-CONICYT for the projects awarded (postdoctoral-Fondecyt N° 3180159, initiation-Fondecyt N° 11150548, Regular-Fondecyt N° 1180063 and Fondap-Crhiam N°15130015).

MO038

Short term air-water exchange of Persistent Organic Pollutants (POPs) in the Concepción Bay, of Central Chile: Is the water body a source or sink of chemicals?

K. Pozo, Masaryk University / RECETOX Research centre for toxic compounds in the environment; V. Gómez, Universita degli Studi di Sienna / Dipartimento di Scienze Ambientali; F. Tucca, Universidad Andrés Bello / Department of Ecology and Biodiversity; P. Pribylova, Masaryk University / RECETOX; C. Galbán-Malagón, Universidad Andrés Bello / Department of Ecology and Biodiversity; O. Audy, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; G. Lammel, Max Planck Institute for Chemistry / Multiphase Chemistry Department; J. Klanova, Masaryk University / RECETOX Research Centre for Toxic Compounds in the Environment; R. Ahumada, Unversidad Católica de la Santísima Concepción

Persistent Organic Pollutants (POPs) are organic compounds resistant to chemical and biological degradation and therefore they can persistent in the environment, they have the potential for bioaccumulation and then can be transferred through the food web until to reach humans. Coastal areas constitute key ecosystems because they provide a link between the ocean and human activities i.e., development of urban areas, industrial settlements, fisheries activities, and others. However, it is well known that the urban development associated with coastal areas lead to an increase in the levels of pollutants in the marine environment. Air and water samples were collected at two sampling sites (Tome and Talcahuano) in Concepción Bay in January 2014 during the Austral summer season. Polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs) and polybrominated diphenyl ethers (PBDEs) were analyzed by means of gas chromatography-mass spectrometry (GC-MS). Results showed POP concentrations in air and water were low, at the two sampling sites for PCBs (3 to 20 pg/m^3), for OCPs: 2 to 120 pg/m^3, and PBDEs (2 to 10 pg/m^3) in air; and in water for PCBs (5 to 40 pg/L), for OCPs: 5 to 40 pg/L, with exception of PBDEs (50 to 20000 pg/L) which was three order of magnitude higher than the other chemicals. Air–water exchange direction was estimated using the fugacity ratio between air and water, the results obtained showed that among the studied compounds HCH isomers and three PBDEs (47, 99 and 100) showed deposition, while on the other hand PCBs, PBDE 209 and HCB showed volatilization. Air-water exchange fluxes estimated ranged from 3.63 to 4736 ng m^2/d for PBDEs, from 1.44 to 23.2 for PCBs and from 1.1 to 32.6 for HCB. The estimated air-water exchange, at both sites, showed volatilization for most of the chemical analyzed with exception of HCHs which was close to the equilibrium state. This condition pointed out that water is the main source of POPs to the atmosphere during the Austral summer. In particular, the resuspension of sediments loaded with PBDEs residue from the Tsunami event that impacted Concepción Bay in February in 2010 due to a local upwelling event that affects the study area during summer.

MO039

Occurrence and Cycling of Persistent Organic Pollutant in an Oligrotrophic Patagonian Lake

T. Luarte, Universidad Andrés Bello / Doctorado en Medicina de la Conservación; F. Tucca, Universidad Andrés Bello / Departamento de Ecología y Biodiversidad; J. Nimptsch, S. Woelfl, Universidad Austral de Chile / Instituto de Ciencias Marinas y Limnologicas; J. Dachs, IDAEA-CSIC / Environmental Chemistry; C.J. Galbán, Universidad Andrés Bello / Department of Ecology and Biodiversity

Persistent Organic Pollutants (POPs) are a diverse group of organic compounds, which are stable and resistant to degradation, prone to bioaccumulate in organisms and biomagnify through the food chain. As a semi-volatile product, they are subject to long-range atmospheric transport (LRAT) through the atmosphere or ocean currents. In addition, because of their toxicity levels, they are harmful to wildlife and human health. The final fate of POPs depends on their physicochemical properties and the processes of exchange between the different environmental compartments. The present work is the result of coupled sampling of air and water during autumn-winter seasons (year 2017). PCB 28, 52, 101, 118, 153, 158 and 180, α-HCB, HCB, β-HCH, ?-HCH, δ-HCH were analyzed using a GC-uECD. Average air and water concentrations for ∑PCB were 28,931 pg m-1 and 219,486 pg L-1; ∑HCB, 0,632 pg m-1, and 26.631 pg L-1; ∑HCH, 82,831 pg m-1, and 908.834 pg L-1, respectively, the concentrations were found to be among the lowest reported for the area both in air and water. For understanding the short-term dynamic between water and air the fugacity ratios ($fw\,fa^{-1}$) for every day were estimated using the concentrations corrected by DOC for each sample. The results showed that deposition dominates over volatilization in all analyzed PCB, HCH congeners, and HCB. The low concentrations found in the water could be explained due to the isolation of the study area and short residence times in the lake that affects the direction of exchange. To date, this is the first report of levels of Persistent Organic Pollutants in Lakes in South Chile.

MO040

Occurrence and distribution of persistent organic pollutants in tissues of green turtles (Chelonia mydas) from Australia

A. Weltmeyer, RWTH Aachen University; L. Weijs, G. Dogruer, Griffith University / Australian Rivers Institute; A. Covaci, University of Antwerp / Toxicological Center; H. Hollert, RWTH Aachen University / Institute for Environmental Research

Antonia Weltmeyer[1], Liesbeth Weijs[2], Gülsah Dogruer[2], Adrian Covaci[3], Henner Hollert[1] [1]Institute for Environmental Research (Biology V), RWTH Aachen University, Aachen, Germany [2]Australian Rivers Institute**,** Griffith University, Brisbane, Australia [3]Toxicological Center, University of Antwerp, Wilrijk-Antwerp, Belgium Persistent organic pollutants (POP) include various anthropogenic chemicals that pose different threats to biota due to their persistence, bioaccumulation and toxicity. They are released into the environment mostly as byproduct of industrial processes (e.g. PDCC/F), directly applied in agriculture (e.g. HCH, HCB) or distributed through incineration (e.g. PCB). While these contaminants have received considerable attention in some marine species, e.g. various marine mammal species, little is known about the bioaccumulation and partitioning of POPs in marine reptiles, such as the green turtle (*Chelonia mydas)*. Green turtles spend most of their life time in coastal areas like seagrass meadows and shallow waters where many anthropogenic chemicals are being released into the marine ecosystem. Even though biomagnification is comparatively low due to their mostly herbivorous lifestyle, POPs have been found in several green turtle populations around the world. Research has also shown comparatively higher POP concentrations in urban and rural agricultural areas of Australia. Such chemical pollution can lead to a general decrease of health and reproduction of the already endangered green turtle. In this study, different tissues (liver, kidney, muscle, adipose tissue) of green turtles from southeast Queensland, Australia, were investigated for their POP load. The following contaminants: 25 PCB congeners, 7 PBDEs, DDT and its major metabolite, DDE, 5 chlordanes, HCB, 3 HCHs and 2 naturally-produced methoxylated PBDEs were targeted. Bioaccumulation of POPs depends on several factors such as tissue type, log Kow values of the compounds, and the age of the animals. The influence of these factors on the partitioning and accumulation of the POPs was investigated in the turtles in this study. This study provides new data in order to raise awareness of the environmental pollution and its consequences for marine biota. Furthermore, an in-vitro bioassay for determination of dioxin-like activity (micro-EROD) will be conducted to assess the health impact of the determined POPs on an individual level.

MO041

Organic pollutants and trace elements as possible drivers for yeast

occurrence in lichens: a case study for an Antarctic ecosystem
C.Z. Cipro, Instituto Oceanográfico da Universidade de São Paulo / LabQOM; P. Bustamante, University of La Rochelle; R.C. Montone, Universidade de Sao Paulo / Oceanographic Institute; M.V. Petry, UNISINOS; L.H. Rosa, Universidade Federal de Minas Gerais; L.D. Sette, UNESP Universidade Estadual Paulista Júlio de Mesquita Filho; A.W. Duarte, Universidade Federal de Alagoas
Antarctica, one of the least polluted regions on Earth, provides unique opportunities for studying environmental pollution processes at both local and global scales. The "global distillation" mechanism is majorly held responsible as the main, or even the only pollutant input process in Polar environments, whilst the biologically mediated transport is frequently not taken into account. However, the role of seabird colonies as relevant secondary sources of both Persistent Organic Pollutants (POPs) and Trace Elements (TEs) was recently reported in literature. The fact that these colonies represent the most important nutrients source to terrestrial ecosystems, inducing a pattern of vegetation around colonies where lichens normally occupy the drier and more distant spots, coupled to their role as pollutant sources results in comparatively high concentrations of POPs and TEs in lichens. In the present work, we hypothesised that these pollutants might influence the quantitative (number of isolates) and qualitative (taxonomic diversity) occurrence of yeasts in lichens from Maritime Antarctica ecosystems. The most common yeast species were *Vishniacozyma victoriae* and *Cystobasidium laryngis*, differently from the ones found directly on bird faeces, rejecting the hypothesis of colonization from the birds themselves. The number of isolates correlated significantly with the taxa and *C. laryngis*, meaning this species is more likely to appear in densely populated substrata. Negative significant correlations were found for the number of isolates with As and Cd, the same case being repeated for the taxa. Indeed another interesting result was revealed for taxa: a significant negative correlation to %N, likely due to a probable ecological dominance mechanism, but also due to the fact that %N and the levels of As showed significant positive correlation, which corroborates its toxicity to yeasts. Principal Components Analysis and Generalized Linear Models ranked by AICc suggested similar adverse influence considering POPs (PCBs and HCB). Therefore, our results suggested deletery effects regarding both yeast quantity and diversity linked to As, Cd, PCBs and HCB, all of them likely supplied by the colonies according to previous studies carried out by the authors. To the best of our knowledge, this is the first work to shed light on this issue.

MO042
Assessment of climate change influences on the exposure level of VOCs and PCDDs/DFs in soil and water of Seoul, Korea
L. Chang, Seoul National University / Environmental Planning Institute Graduate School of Environmental Studies; Y. Lee, Seoul National University; H.S. Kim; D. Lee, Seoul National University / Environmental Planning Institute Graduate School of Environmental Studies
Influence of climate change (CC) was assessed on the environmental levels of three VOCs (benzene, toluene, and formaldehyde) and three PCDDs/DFs (2,3,7,8-TCDD, 1,2,3,6,7,8-HxCDF, and OCDF) using a regional-specific multimedia fate model (KPOP-CC). The predicted average concentrations in soil and water over each of the three 20 year periods (2021 to 2040 (F1), 2051 to 2070 (F2), and 2081 to 2100 (F3)) were compared to those of the period of 1986 to 2005 (BASE) under the RCP8.5 scenario in Seoul, Korea. The average concentrations of VOCs in soil and water increase by up to 109% and 87%, respectively, as compared to BASE. As CC progresses, however, the average concentrations gradually decrease to give F1>F2>F3. Model prediction indicates that the decreasing concentrations of VOCs in soil and water with the CC periods are governed by the increased volatilization loss to air followed by increased degradation. The average concentrations of PCDDs/DFs in bare soil and forest soil increase by up to 562% and 2300%, respectively, while by up to 419% in water. On a monthly bases, the increase in the concentration in water is over 3392% in June. Atmospheric PCDDs/DFs are input to soil mainly in the particulate form and accumulate in soil due to their persistence. In bare soil, PCDDs/DFs concentrations in F3 are lower than those in the periods of F1 and F2 because of the decrease in wet deposition of atmospheric particles in F3. In forest soil, however, wash-off of the particle-bound PCDDs/DFs from vegetation surfaces dominates during wet period, hence the average concentrations of PCDDs/DFs increase as CC progresses from F1 to F3. Increase of solid runoff caused by the increase in the precipitation intensity leads to the substantial increase of the concentrations in water. These results clearly demonstrate that i) the CC influence on the environmental level of chemical compounds can substantially vary with their physicochemical and fate properties and ii) CC may considerably increase the environmental health risk from neutral hydrophobic SVOCs (e.g., PCDDs/DFs) in the soil and water ecosystems.

MO043
Prediction of Bioaccumulation Potential for Ionizable Chemicals Based on COSMO-RS
J.A. Schwöbel, A. Klamt, COSMOlogic
There is a high demand for reliable and robust methods to predict the bioaccumulation potential for agrochemicals, pharmaceuticals as well as industrial chemicals, in order to access the long-term and chronic toxicity. Currently, the bioaccumulation potential is assessed in a tiered approach via octanol-water partition coefficients at the first stage. However, this approach is not applicable for organic ions and ionizable chemicals, because the latter have different mechanisms of sorption. It is therefore important to develop new screening tools that work for ionizable and ionic chemicals.[1] As an alternative, sorption models are proposed including storage lipids, phospholipid membrane lipids and proteins. Partitioning into storage lipids (*rmsd* up to 0.35) and proteins (*rmsd* = 0.57), pK_a values and fractions of different protonation states are calculated by the COSMO-RS (Conductor-like Screening Model for Realistic Solvation) approach.[2,3,4,5] The COSMO*mic* extension for the COSMO-RS treatment of inhomogeneous phases is used to calculate the partitioning into biomembranes (*rmsd* = 0.70).[6] COSMO-RS is based on first-principle quantum chemical structures, and uses physically sound intermolecular interactions (electrostatic, hydrogen bond and van der Waals), including the handling of protonated states and ionic structures. For this reason, it is unbiased towards different application scenarios, as industrial chemicals, agrochemicals and pharmaceuticals. Two approaches will be demonstrated: at first, a static model, based on a recently published model for the bioconcentration potential in fish[1]; at second, a simple toxicokinetic model for terrestrial organisms, which does take into account the uptake via different routes and biomembrane permeabilities. The latter could allow for a species-to-species extrapolation and, thus, a consideration of impacts on non-target species in the ecosystem. [1] Bittermann et al., Environ. Sci.: Processes Impacts, 2018, 20, 845 [2] Klamt et al., J. Phys. Chem. A, 1998, 102, 5074; [3] Klamt, WIREs Comput. Mol. Sci., 2017, e1338 [4] Klamt et al. J. Comp. Aid. Mol. Des., 2016, 30, 959 [5] Geisler et al., Environ. Sci. Technol. 2015, 49, 5538 [6] Bittermann et al., J. Phys. Chem. B, 2014, 14833

Endocrine Disruption in Invertebrates: Historical Perspectives, New Developments, and Key Research Needs (P)

MO044
Acute toxicity of ethylparaben to Daphnia similis
R. Maia Valença, University of Sao Paulo - USP / Chemistry and Molecular Physics; M. Pomaro Casali Pereira, Sao Paulo University / Departament of hidraulic and sanitary engineering; R.T. Verbinnen, University of São Paulo USP / Department of Molecular Chemistry and Physics; R.A. Moreira, University of São Paulo / São Carlos School of Engineering; E.M. Vieira, University of São Paulo / Institute of Chemistry of Sao Carlos
The increasing industrial activity along urban growth has accelareted the disposal of several pollutants in water bodies. Analytical methods have been developed as there is an arising concern with emerging contaminants. These chemical substances are found in surface water in low concentrations and can resist to the sewage and industrial wastewater treatment systems. Parabens are considered a noxious group of chemical preservatives with high industrial usage that threaten both the human health and the biologic communities of aquatic ecossystems due to its toxicity and their endocrine disruption potential. Ethylparaben, one of the most widely used variety of the parabens can also be accumulated throughout the trophic levels because of its high k_{ow} value. Therefore, it is extremely important to evaluate its toxicity for environmental legislation and ecological risk assessment. Cladocera represents one of the most important group in the zooplanktonic community regarding energy transfer along the food chain. Because of their short life cycle and their high sensibility to aquatic pollutants, they are widely used in ecotoxicological tests. This study evaluated the sensitivity of *Daphnia similis* to ethylparaben according to the OECD guideline 202 on *Daphnia* sp., acute immobilization test and reproduction test. The tests concentrations were determined by HPLC-DAD analyses. Comparing the results of the present study to the literature, it may be concluded that the *Daphnia similis* specie (EC50 = 23.70 mg L-1) is more sensitive to ethylparaben than the *Daphnia magna* (EC50 = 32 mg L-1), the *Dugesia japônica*(EC50 = 31 mg L-1) and the *Photobacterium leiognathi*(EC50 = 25 mg L-1). Many studies of fresh water monitoring have reported the presence of parabens in concentrations of μg L-1. This emphasizes the importance of researching the effect of environmental concentrations of parabens on reproductive, fisiologic and comportamental parameters of *D. similis* specie.

MO045
Adverse effects of mono-(2-ethylhexyl)-phthalate on Daphnia magna in acute and chronic test
Y. Seol, KIST-Europe / Environment Safety group; Y. Kim, M. Baek, C. Ryu, D. Kim, KIST-Europe
Mono-(2-ethylhexyl)-phthalate (MEHP) is the metabolite of di-(2-ethylhexyl)-phthalate (DEHP), which is widely used in the industry as plasticizers. According to previous studies, both MEHP and DEHP causes oxidative stress and are considered as reproductive toxicants in various organisms. MEHP is highly persistent and bioaccumulative in environment and living organisms. However, little is known about toxicity of MEHP to aquatic invertebrates such as *Daphnia magna*. The aim of this study was to elucidate the mechanism of MEHP toxicity in *D. magna*. It is interesting that LC_{50} of MEHP were 85.2 mg/ L^{-1} for 48 h which

were higher than known LC_{50} (0.56 mg L^{-1}) of DEHP. We studied the effects of oxidative stress as molecular initiating events on *D. magna*. *D. magna* (5 d) were exposed to MEHP for 6 h and 24 h for observing the changes in different levels of the Reactive Oxygen Species (ROS), glutathione S-transferases (GSTs), GSH/GSSG ratio. In addition, expression levels of glutathione related genes and juvenile hormone genes were utilized to understand the toxic mechanism of MEHP. Lastly, the reproduction rate and growth of daphnids during chronic (21 d) test were included in this study. Further study is needed to clarify how MEHP leads to dysfunction of reproduction system of *Daphnia magna*.

MO046

Biomarkers of intersexuality and reproductive dysfunction in crustaceans

S. Short, Cardiff University; G. Yang, Y. Guler, University of Portsmouth; A. Green Etxabe, CEH Wallingford; P. Kille, Cardiff University; A. Ford, University of Portsmouth / Biological Sciences

Despite the well-documented cases of endocrine disruption in vertebrates and some molluscan groups, it is currently unknown whether reproductive endocrine disruption represents a threat to crustacean populations. The study of widespread intersexuality provides an opportunity to investigate sexual differentiation and dysfunction. Crustacean intersexuality is associated with contamination and includes forms linked to increased sex-ratio distorting parasites at polluted sites. Despite the importance of crustaceans for monitoring vulnerable aquatic habitats, little is known about the molecular basis intersexuality or any associated sexual dysfunction. To increase the relevance of crustaceans to environmental toxicologists, this study comprehensively analyzed gene expression in amphipods presenting parasite and non-parasite associated intersexuality. We suggest existing vertebrate biomarkers of feminization should not be applied to crustaceans, as orthologous genes are not induced in feminized amphipods. Furthermore, in contrast to vertebrates, where feminization and intersexuality are often associated with deleterious de-masculinization, we find males maintain masculinity even when unambiguously feminized. This reveals a considerable regulatory separation of the gene pathways responsible for male and female characteristics and demonstrates that evidence of feminization (even if detected with appropriate biomarkers) is not a proxy for de-masculinization in crustaceans. This study has also produced a comprehensive spectrum of potential molecular biomarkers that are currently being applied to specimens collected from clean and industrially impacted locations. This will represent the first application of appropriate transcriptomic biomarkers to monitor feminization and de-masculinization in field populations of crustaceans.

MO047

Characterization and transcriptional response of ecdysone receptor gene in the mud crab Macrophthalmus japonicus: effects of osmotic stress and endocrine disrupting chemicals

K. Park, H. Jo, Chonnam National University; I. Kwak, Chonnam National University / Faculty of Marine Technology

Ecdysone receptor (EcR) induces hormonal pathways by binding ecdysteroids to other nuclear receptors for development, reproduction, and molting processes. To further understand the role of EcR in polluted environments, we have characterized EcR, and assessed transcriptional responses of the EcR gene to osmotic stress, and to endocrine disrupting chemicals (EDCs) such as bisphenol A (BPA) and di-(2-ethylhexyl) phthalate (DEHP) in the intertidal mud crab *Macrophthalmus japonicus*. Phylogenetic analysis showed that the ligand binding domain of *M. japonicus* EcR formed two different clusters among crab species. Osmotic stress prompted different expression patterns of EcR mRNA in *M. japonicus* crabs under low and high salinity. BPA exposure induced significant up-regulation of EcR as early as day 1 in *M. japonicus* gills and hepatopancreas. However, the expression levels of EcR returned to similar, or lower, levels as controls, by days 4 and 7. In contrast, EcR mRNA expression was significantly induced in *M. japonicus* gills and hepatopancreas exposed to all concentrations of DEHP over all exposure times. Hepatopancreatic tissue is more sensitive than gill tissue in terms of EcR gene responses to EDCs. Taken together, these results suggest that the role of EcR in endocrine protection involves different processes, according to the type of EDCs involved, and that up-regulatory responses by EcR indicate the response of hormonal regulatory processes to environmental changes induced by osmotic stress or EDC exposure.

MO048

Chronic effects of bisphenol S and bisphenol SIP on Daphnia magna and Moina macrocopa and ecological risk assessment

K. Ji, Y. Hong, J. Lee, Yongin University

In response to the regulatory pressures to eliminate bisphenol A (BPA) in plastics, bisphenol S (BPS) and 4-hydroxyphenyl 4-isoprooxyphenylsulfone (BPSIP) have been frequently used in manufacture of thermal paper and plastic containers. However, there is paucity of information on their chronic toxicity using aquatic invertebrates and associated ecological risk. In the present study, chronic toxicity of BPS and BPSIP were evaluated using two freshwater invertebrate species, i.e., *Daphnia magna* and *Moina macrocopa*. The body length was significantly decreased in *D. magna* exposed to 5 and 10 mg/L of BPS, and 1 mg/L of BPSIP. The reproduction NOEC value in *M. macrocopa* was 0.03 mg/L of BPS and 0.1 mg/L of BPSIP. Based on the toxicity values from the present study and literature, the predicted no effect concentration (PNEC) of BPA, BPS, and BPSIP was calculated. For the BPA and BPS in which the measured environmental concentration of surface water worldwide is present, the hazard quotient (HQ) was derived for the ecological risk assessment. The HQs of BPA and BPS toward aquatic organisms were calculated to be greater than 1.0, indicating that potential ecological risk currently. With increasing use of these alternative compounds, more monitoring program in aquatic environment and study of toxicity mechanism appeared to be necessary. Acknowledgement - This study was supported by the National Research Foundation of Korea (Project NRF-2015R1D1A1A01056628).

MO049

Comparative study of the effect of bisphenol A (BPA) and two analogs, bisphenol S (BPS) and bisphenol F (BPF), on the endocrine system of Chironomus riparius larvae

M. Morales Camarzana, Universidad Nacional de Educación a Distancia / Fisica Matematica y de Fluidos; J. Martinez-Guitarte, UNED / Fisica Matematica y de Fluidos; R. Martín Folgar, UNED / Física matemática y fluidos

There is increasing evidence that bisphenol A (BPA, 2, 2-bis [4-hydroxyphenyl] propane), used in plastics and other products, could be harmful to human health due to its association with diseases such as obesity, diabetes, reproductive disorders and cancer. Many *in vitro* and *in vivo* research studies, have demonstrated the ability of BPA to act as an endocrine-disrupting chemical (EDC) and have attributed its exposure to cytotoxic, genotoxic and carcinogenic effects. BPA has been widely used for the manufacture of polycarbonate plastics and epoxy resins. The exposure of humans occurs through food in contact with the materials that contain them, such as polycarbonate bottles, plastic food containers, etc. So, bisphenol S (BPS, bis [4-hydroxyphenyl] sulfone) and bisphenol F (BPF, bis [4-hydroxyphenyl] methane) are already being used for a variety of industrial applications as BPA alternatives. BPS is used as an agent in cleaning products and as a developer in thermal paper, including products marketed as "BPA-free paper". BPF is used to make epoxy resins, coatings, adhesives for several consumer products, food packaging, etc. BPA-like effects of BPS and BPF can be hypothesized because their chemical structures are similar. Some studies have analyzed *in vitro* the hormonal actions of BPA analogues, demonstrating they have actions similar to those of the original compound, which supports the possibility of being hormonally active. However, it is necessary to study the physiological effects and endocrine activities of BPA substitutes *in vivo*. The main objective of this study was to evaluate different metabolic pathways of action of BPS and BPF compared to BPA, in four instar *C. riparius* larvae, an aquatic invertebrate widely used in environmental toxicology. The transcriptional activity of four genes involved in the endocrine pathway (Cyp18a1, shadow, ECR and E74), one gene related to apoptosis (DRONC) and a multi drug resistance gene (MRP1) were evaluated by real time RT-PCR in *C. riparius* larvae during 24 hours of BPA, BPS and BPF exposures at 0.05, 0.5 and 1 mg/L. The obtained results show similar patterns of BPA, BPS and BPF transcriptional expression when compare the Cyp18a1, DRONC, and shadow genes. These results suggest a similar gene activation model for the three compounds employed, which implies the need to carry out more *in vivo* studies to evaluate the hormonal actions of BPA analogues. Possibly BPF and BPS are not a safe alternative to BPA.

MO050

Effect of glyphosate-based herbicides on relative transcript expression levels of genes involved in growth and reproduction in the decapod Macrobrachium potiuna

M. Melo, Universidade Federal de Santa Catarina / Laboratório de Reprodução e Desenvolvimento Animal; E.M. Nazari, Y.M. Müller, Universidade Federal de Santa Catarina / Biologia Celular Embriologia e Genética; C. Joaquim-Justo, University of Liege / Laboratory of Animal Ecology et Ecotoxicology; E. Gismondi, LEAE - University of Liege / Laboratory of Animal Ecology et Ecotoxicology

Glyphosate based herbicides (GBH) are the most commonly used herbicides worldwide. In the environment, glyphosate has been detected in sediments, surface and groundwater. Thus, the species that inhabit these ecosystems are exposed to this contaminant. Although, animals lacks the metabolic pathway of the GBH action, several studies has been demonstrating the toxic effects of GBH exposure on animals, mainly related to oxidative stress, genotoxicity, cytotoxicity, neurotoxicity and teratogenicity. Moreover, for vertebrate models, glyphosate is known as an endocrine disruptor, mimicking the effect of sexual and growth hormones, thus, biomarkers for the assessment of endocrine disruption caused by GBH exposure have been developed. However, currently, no biomarkers are available to assess the endocrine disruption in decapod crustaceans exposed to GBH. Thus, the aim of this study was to assess the effects of low GBH concentrations on the relative transcript expression levels of the molt-inhibiting hormone (MIH), the ecdysteroid receptor (EcR) and the vitellogenin (Vg) genes involved in the process of molting and reproduction on the prawn *Macrobrachium potiuna*. Males and females were exposed to GBH (0.00; 0.0065, 0.065 and 0.28 mg L^{-1}) for 7 and 14 days. Next, the relative transcript expression levels of these three genes have been measured by RT-qPCR, for each gender and time of exposure. Males exposed for 7 days highlighted overexpression of EcR and MIH, while the opposite was observed in Vg, being overexpressed in prawns exposed for 14 days. Furthermore, it was observed a time-dependent effect mainly in the two higher concentrations. For females exposed for 7 and 14 days, no alteration was observed in EcR and Vg expression, but it was observed a time-dependence effect mainly in the 0.0065 and 0.065 mg L^{-1} concentrations. Therefore, this work underlined that exposure to GBH also affect invertebrate species and can modulate the expression of genes involved in the molting and reproduction. The obtain results are promising in the development of future biomarkers for GBH exposure in crustaceans. Nonetheless, further studies are needed to better understand the variations of these genes and their application in field assays, before to use them as biomarkers.

MO051

Effects of anti-androgen compounds on the relative expression of the retinoid X receptor gene of the rotifer Brachionus calyciflorus

E. Gismondi, LEAE - University of Liege / Laboratory of Animal Ecology et Ecotoxicology; L. Woeffler, University of Liege; C. Joaquim-Justo, University of Liege / Laboratory of Animal Ecology et Ecotoxicology

Rotifers are widely used as bio-indicators and models for ecotoxicology due to their sensitivity to various toxicants, but also other characteristics such as short generation time, ease of culture in small volumes, ease of establishing clone cultures. Although many studies highlighted that endocrine disruptor compounds (EDCs), especially anti-androgen compounds, impact the population fitness of rotifers (e.g. population growth, fecundity, cyst production), endocrine mechanisms mediating these effects remain obscure, probably due to the limited knowledge on endocrine systems in rotifers. The retinoid X receptor (RXR) is a nuclear receptor which has been shown to be involved in the imposex induction in gastropods. Based on this information, we aimed to evaluate in the monogonont rotifer *B. calyciflorus*, the effects of three anti-androgen compounds (i.e. flutamide, fenitrothion, cyproterone acetate) on the relative expression of the RXR gene, in order to improve the understanding of the mechanisms of action of these EDCs. For each compound, three concentrations were chosen according to their respective NOEC value, and *B. calyciflorus* were exposed for 6hrs, 12hrs and 24 hrs. Results highlighted that RXR relative expression was under-expressed in *B. calyciflorus* exposure at the three anti-androgen compounds, suggesting that RXR could be involved to demographic effect previously observed (e.g. decrease in resting eggs produced, fertilization – Tian et al. 2017). Nevertheless, more investigations are needed to understand the endocrine disruption mechanism.

MO052

Effects of tributyltin (TBT) exposure on gametogenesis and sex ratio in the European flat oyster (Ostrea edulis)

L.M. Zapata-Restrepo, M.D. Hudson, University of Southampton / School of Geography and Environmental Sciences; C. Hauton, National Oceanography Centre, University of Southampton / School of Ocean and Earth Science; I.D. Williams, University of Southampton / Faculty of Engineering and Physical Sciences; D. Hauton, Oxford University / Department of Chemistry; A. Jensen, National Oceanography Centre, University of Southampton / School of Ocean and Earth Science

Tributyltin (TBT) compounds have been used for various purposes including antifouling paints for boats, preservatives and antimicrobial agents. Although restricted in many countries due to their relative persistence, tendency to bioaccumulate and toxicity, they are now widespread global contaminants that persist in natural environments. TBT, and its derivatives, have shown adverse effects including mortality and masculinization in form of imposex or intersex in gastropods. Although TBT has been one of the most extensively studied examples of endocrine disruption in gastropods, the underlying mechanism in oysters remains unclear. The flat oyster *Ostrea edulis* (Linnaeus, 1758) is a commercially valuable species in Europe but its populations have collapsed in recent decades. In the Solent, Southern England, one such populations of oysters has seen a significant reduction in the number of brooding female-phase oysters and skewed sex ratio towards male-phase oysters in recent years. In order to understand the effect of TBT exposure on gametogenesis and the potential mechanism of disruption on gender determination, oysters (n=30) were exposed to 20 ng/L, 200 ng/L and 2000 ng/L TBT chloridefor two months. At the end of the exposure, gametogenic stage and sex ratio were assessed histologically and metabolomic profiling analysis was conducted to elucidate themetabolic alterations that occur in individuals exposed to TBT. Our results showed a significant concentration-dependent increase in mortality. Moreover, at 20 ng/L and 200 ng/L TBTCl the proportion of *O. edulis* individuals developing as males or were undifferentiated increased respect to the control group. At 2000 ng/L TBTCl no males were found but the proportion of undifferentiated oysters was significantly higher compared to the control. The metabolome of TBTCL exposed oysters demonstrated changes in energy metabolism-related pathways and cortisol levels as compared to control group. In total, our results indicate that gametogenesis and sex determination in *O. edulis* can be affected by TBT exposure creating a bias toward males this species. However, high concentrations of this compound could increase mortality rather than effect reproduction. The presence and persistence of TBT in the environment could cause an additional threat to the declining *O. edulis* populations around the world, by increasing mortality, changing reproductive maturation and skewing sex-ratios in natural populations.

MO053

Endocrine disruptors in the aquatic environment: Is it enough to screen for estrogens only?

S. Faetsch, Hamburg University of Applied Sciences (HAW)

Endocrine disrupting chemicals (EDCs) mimic the behaviour of natural hormones and are suspected to disturb reproduction and development in wildlife (1, 2). The chemicals receiving most attention are those interfering with functions of the vertebrate sex hormone estrogen, the so-called xenoestrogens (2, 3, 4). Potential EDCs that may affect other ecologically and economically relevant phyla that do not possess estrogen receptors, such as aquatic arthropods (e.g. daphnids, shrimps and crabs) are rarely addressed (5). The key hormone in arthropod molting is 20-hydroxyecdysone (20E), yet the response of the ecdysone receptor (EcR) to environmental stressors (e.g. insecticides with endocrine disrupting potential) is not well understood (6, 7). Since the EcR system is highly conserved across taxa, non-target organisms of insecticides, such as crustaceans, could be adversely affected (5). Bisacylhydrazines, a widely applied group of insecticides in fruit farming, act as non-steroidal 20E agonists that can disrupt normal EcR function (3, 6, 8). They are supposed to be highly species-specific and thus environmentally safe (3, 9). This, however, is contradicted by reports of toxicity in the low concentration range of $\mu g\ L^{-1}$ of active ingredient towards non-target organisms, e.g. the crustacean *Daphnia magna* (9, 10). Two receptor activity luciferase reporter gene assays (11, 12) will compare the effect of environmental samples on estrogen and ecdysone receptor activities. Sampling stations cover different pollutant scenarios. They are located in proximity to a waste water treatment plant, where higher levels of estrogenic compounds are expected, in addition to areas of extensive fruit farming where ecdysonic compounds might prevail. 1. Transcriptional profiling of heat shock proteins expressions to osmotic and endocrine disrupting stress in mud crab Macrophthalmus japonicus

K. Park, H. Jo, Chonnam National University; I. Kwak, Chonnam National University / Faculty of Marine Technology

Heat shock proteins (HSPs) play crucial roles in the cellular metabolite process as well as protective immune responses.In the study, we investigated the transcriptional profiling of six HSPs in mud crab *Macrophthalmus japonicus* under osmotic and endocrine disrupting chemical stress. The mRNA expressions of HSPs showed differently in the gills as up-regulations of HSP70, HSP90, and HSP40 or down-regulations of HSP60 under high salinity. In hepatopancreas, under osmotic stress, the responses of most HSPs genes showed up-regulation at early exposure time and down-regulation at late exposure time. In addition, Bisphenol A (BPA) exposure mostly induced responses of HSPs in gills. In hepatopancreas, HSP70 and HSP90 gene expressions showed up-regulation, whereas the transcriptional expressions of HSP60, HSP83, and HSP21 showed down-regulation at day 1 and day 4. These results suggest that HSPs are involved differently in the molecular adaptation and defense responses of crabs to BPA and osmotic stress.

MO055

Using a RT-PCR array for the analysis of single, binary, and ternary mixture exposure of UV filters Octocrylene and OD-PABA and Bisphenol A on Chironomus riparius.

A.M. González, UNED / Mathematical Physics and Fluids; J. Martinez-Guitarte, UNED / Fisica Matematica y de Fluidos

The presence of UV filters in the environment has been increased in recent years, cataloging them as emerging pollutants. The aquatic systems are especially affected due to recreational activities as well as the absence of specific treatments in Waste Water Treatment Plants (WWTP). Previous studies showed endocrine disruption, but studies focused on invertebrate organisms are scarce. In parallel, bisphenol A is one of the main plasticizers used in packaging and other industrial products. Multiple studies have evaluated its effects, concluding that it is an endocrine disruptor. In order to make an evaluation closer to the environmental conditions, we have analyzed the effects of individual, binary, and ternary mixtures of Bisphenol A and two UV filters, Octocrylene (OC) and 2-ethylhexyl 4- dimethylaminobenzoate (OD-PABA), on fourth instar larvae of *Chironomus riparius*. These mixtures usually reach to freshwater ecosystem so the main objective was to determine the effects in gene expression of this species, which has a relevant role in the food chain of these ecosystems. In order to evaluate the response at short and medium term, larvae were exposed for 24 and 96 hours to 0.1 and 1 mg/L of single compounds and to binary and ternary mixtures. It is known that exposure to toxicants can alter different metabolic pathways, generating a domino effect. Thereby, the expression profile of 40 genes was analyzed by retrotranscription and Real-Time PCR using a specific array covering a number of relevant metabolic pathways related with endocrine system, immune response, stress response, detoxification mechanisms, and apoptosis among others. These studies open up new opportunities in the design and identification of molecular biomarkers for toxicological evaluation and ecological risk assessment. The methodology used in the design of the array can be extrapolated for other species. This work has been funded by the Ministerio de Economía y Competitividad, CICYT (SPAIN), CTM2015- 64913-R. A.B.M.G is the receiver of a pre-doctoral contract from the National University of Distance Education (UNED).

Validation of the protocol of juvenile hormone activity screening assay (JHASA) proposed to OECD

R. Abe, National Institute for Environmental Studies; H. Watanabe, National Institute for Environmental Studies / Center for Health and Environmental Risk Research; M. Ogawa, Kumiai Chemical Industry Co. Ltd; R. Adachi, Chemicals Evaluation and Research Institute, Japan; T. Okamura, IDEA Consultants, Inc.; T. Matsumoto, Nisso Chemical Analysis Service Co., Ltd. / Ecotoxicology; A. Okamoto, Nisso Chemical Analysis Service Co., Ltd. / Department of Ecotoxicology, Odawara Laboratory; N. Tatarazako, Ehime University / Environmental Risk; H. Yamamoto, National Institute for Environmental Studies / Center for Health and Environmental Risk Research

After we had found the juvenile hormone agonists for *Daphnia magna* more than ten years ago by Tatarazako et al. (Chemosphere, 53:827-33, 2003), we have found several agonists such as diofenolan (Abe et al., Aquat Toxicol, 159:44-51, 2015). We had also proposed a confirmation test protocol for juvenile hormone to OECD and it was admitted as annex 7 of Guideline for Testing of Chemicals No. 211. However, it takes whole 21 days of the testing period to fully conduct this standardized test and it is highly time-consuming to observe all the neonates to check their sex. So, we proposed short-term screening test using *D. magna* of 10-17 days old based on our previous study (Abe et al., J App Toxicol, 35:75-82, 2015) to observe the sex of the neonates for seven days, and currently under discussion in OECD expert meeting as Juvenile Hormone Activity Screening Assay (JHASA). The experts also commented to concern the possible effects of non-chemical stress such as temperature, light cycle, and hardness. So, we decided to conduct ring tests with five laboratories (three CROs, a chemical manufacturer, and our institute) in Japan to validate the proposed protocol of JHASA using two chemicals, one is a positive control and the other is a negative control. The results were compared in detail in terms of the difference in the laboratories and slight difference in *D. magna* strain. We are also going to show some of the preliminary results of the potential non-chemical stresses.

MO057

Effects of ten bisphenol analogs on thyroid endocrine system and possible interaction with 17β-estradiol using GH3 cells

J. Lee, Yongin University; S. Kim, Seoul National University; K. Choi, Seoul National University / School of Public Health; K. Ji, Yongin University

In response to the bisphenol A (BPA) regulation, various bisphenol analogs (BPs) have been widely used. However, the potentials of thyroid endocrine disruption and mixture toxicity with other environmental contaminants were not investigated as much as their estrogen disruption potential. In the present study, two sets of *in vitro* rat pituitary (GH3) cell assays were designed. In the first set of experiments, changes in GH3 cell proliferation were examined after 48 h and 96 h exposure to each of ten BPs (BPA, BPAF, BPAP, BPB, BPC, BPF, BPM, BPP, BPS, BPZ), in the absence or presence of a median effective concentration (6.4×10^{-10} M) of triiodothyronine (T3). All tested BPs maximally stimulate GH3 proliferation at a dose of 10^{-6} M, suggesting that BPA and its analogs behave like thyroid hormone (TH) agonist, at least some extent. BPs did not potentiate the T3-induced cell proliferation at 48 h exposure, while several tested BPs including BPA, BPAF, BPB, BPF, BPS, and BPZ elicited a potentiating effect on the T3-induced cell proliferation at 96 h exposure. These results indicate that TH-antagonistic effects of BPs depend on the tested dose and exposure time. In the second set of experiments, one of the most potent BPs, i.e., BPAF, was selected, and its possible interaction with 17β-estradiol (E2) on the thyroid endocrine system was evaluated. A combined treatment with BPs and E2 induced additive-like effects on GH3 cells, and the increase in cell proliferation and inhibition of gene transcription (*Trα*, *Trβ*, and *Dio2*) were more pronounced with the BPAF and E2 combination than with the BPA and E2 combination. Our observations suggest that adverse effects might be more pronounced using BPA analogs, and the effects of BPA on the thyroid endocrine system might be even greater than that expected, because of potential interactions with other common hormones such as E2. Although detailed mechanisms and implication of endocrine disruption by BPs warrant further studies, our findings are important as E2 is naturally present in biota and therefore BP absorption by organisms would inevitably lead to an interaction with E2.

Development of Short-Term Toxicity Test Methods to Estimate Chronic Toxicity using the Freshwater Parthenogenic Mayfly, Neocloeon triangulifer

D.J. Soucek, University of Illinois, Urbana-Champaign / Illinois Natural History Survey; A. Dickinson, Illinois Natural History Survey / Ecology; T.J. Norberg-King, U.S. Environmental Protection Agency / NHEERL/Mid-Continent Ecology Division

For decades, toxicity tests with aquatic invertebrates have been conducted and yet a small number of model organisms are routinely used. Test organisms are usually easily cultured in the laboratory, have rapid life-cycles, exhibit sensitivity to a variety of pollutants with reproducible results, and are generally available year-round. The US EPA effluent testing program uses short-term chronic freshwater tests (4d to 8d) with cladocerans (Cladocera, *Ceriodaphnia dubia)*, green algae (Sphaeropleales, *Raphidocelis subcapitata*) and fish (Cypriniformes, *Pimephales promelas)*. These species have been used extensively in acute and short-term toxicity tests using EPA standardized methods to assess the hazard of chemicals and effluents in freshwater environments. EPA has standardized *Hyalella azteca* (Amphipoda) and *Chironomus dilutus* (Dipteran*) test*methods for sediments; yet EPAs effluent and ambient testing manuals don't provide acute or short-term test methods for *H. azteca*, *C. dilutus* or mayflies (Ephemeroptera, *Hexagenia*, *Neocloeon*). To add a sensitive insect, we have focused on using the mayfly, *N. triangulifer*, as it is parthenogenetic, has a short life cycle (~30d at 25C), and is sensitive to various toxicants. While methods for conducting acute 4d and chronic (~25-30d) toxicity tests with this mayfly have been published, a need exists to extend and standardize the methodology for applicable methods for testing in short-term exposures (e.g., 7d or 10d). Studies began with identifying an optimal starting age, test duration, and optimal sublethal endpoint for whole effluent toxicity testing. While others have compared the sensitivity of this species at 0d, 3d, & 5d old, we sought to further investigate this question with independent experiments comparing 0d and 7d old organisms in 7d and 14d tests. We developed a length versus dry weight relationship for this mayfly; dry weight is a more sensitive endpoint than length, but length is easier to measure more consistently and accurately with young instars. Efforts to refine the various aspects of diatom culture technique on food quality and therefore mayfly growth are underway and optimizing the diet for these organisms may be critical for achieving consistently high growth rates with low intra-treatment variability. Results of the study should provide data needed to guide the development of a toxicity test method to support NPDES permit decision-making. *This abstract does not necessarily represent the position or policy of the USEPA*. \n

MO060

Development of Short-Term Toxicity Test Methods to Estimate Chronic Toxicity using the Freshwater Mussel (Fatmucket, Lampsilis siliquoidea)

T.J. Norberg-King, U.S. Environmental Protection Agency / NHEERL/Mid-Continent Ecology Division; N. Wang, J.L. Kunz, J.A. Steevens, U.S. Geological Survey / Columbia Environmental Research Center; E. Hammer, USEPA Region V / Water Quality Branch, Chicago, IL; C. Bauer, U.S. Environmental Protection Agency / WED; C. Barnhart, Missouri State University / Biology

For decades, toxicity tests with aquatic invertebrates have been conducted, and yet a small number of model organisms are routinely used. The US EPA effluent testing program uses short-term chronic freshwater tests (4 to 8d) with cladocerans (Cladocera, *Ceriodaphnia dubia)*, green algae (Sphaeropleales, *Raphidocelis subcapitata*) and fish (Cypriniformes, *Pimephales promelas)*. These species have been used extensively in acute and short-term toxicity tests using USEPA standardized methods to assess the hazard of chemicals and effluents in freshwater environments. While USEPA has standardized *Hyalella azteca* (Amphipoda) and *Chironomus dilutus* (Dipteran*)* test methods for sediments; USEPAs effluent and ambient test manuals don't provide acute or short-term test methods for *H. azteca*, *C. dilutus*, mayflies or mussels. To add another sensitive species, we have focused on method development using the fatmucket mussel (*Lampsilis siliquoidea*) for effluent toxicity assessments. A feeding study was conducted using a mixture of algal and shellfish foods with various starting ages of juveniles (~1, 2, 3 wk old mussels) in both 7d and 10d tests. Growth (shell length) at the feeding rate of 2 mL/2X/d with either 1 or 2 wk old mussels (~0.3-0.4 mm) and 3 mL/2x/d for 3 wk old mussels (~0.5 mm) provided consistent growth. Mean survival was ≥93% in all feeding treatments except for the 4 ml/1x/d to 1 wk-old mussels (78%). The increase of mussel shell length ranged from 24-52% at 7-d and from 28-60% at 10-d among four feeding treatments. Once the optimum feeding rate was determined, three ages of juveniles were exposed to a reference toxicant (NaCl) for 7d & 10d tests. For both durations, growth (length) was consistently more sensitive than survival, and with juvenile mussels growing over 50% in a short-term test (7d or 10d). The sensitivity to NaCl was mostly the same when tests were initiated with 1, 2 or 3-week-old mussels. To further evaluate the performance and variability in the mussel method, an interlaboratory study with 13 volunteer laboratories from the United States and Canada was conducted using 1-wk-old mussels and NaCl for a 7-d test. In this poster, we will present detailed results of the feeding studies, the relative sensitivity and the interlaboratory results along with a discussion of how the mussel procedure can complement current effluent and receiving water testing. *This abstract does not necessarily reflect the views or policies of the US Environmental Protection Agency. \n*

MO061

A new network of in silico models to cope with REACH requirements for (Q)SAR and read-across: the LIFE CONCERT REACH project

R. Gonella Diaza, A. Szymoszek, A. Gerloff-Elias, knoell Germany GmbH; E. Benfenati, Istituto di Ricerche Farmacologiche Mario Negri IRCCS / Department of Environmental Health Sciences, Laboratory of Environmental Chemistry and Toxicology

LIFE CONCERT REACH is a new EU funded four-year project started in September 2018 [1] in which research institutes and consultancy companies are involved. The project is dedicated to establish a network of *in silico* models (i.e. (Q)SAR and automated read-across). On the one hand, it aims to link existent and well established *in silico* platforms (i.e. VEGA, The Danish QSAR database and AMBIT) to a new “super” platform. On the other hand, it will integrate new models, with the aim of covering virtually every possible environmental and (eco)toxicological endpoint required within the framework under Regulation EC (No) 1907/2006 (REACH). The development and implementation of an automated system is one key objective of the project, aiming to integrate several new *in silico* approaches, and to develop an automated tool able to combine multiple results (including potentially available experimental data) using weight of evidence approaches (WoE). The ambitious goal of the project is to offer more than 300 freely available *in silico* models within the same platform. Both (Q)SAR models and read-across tools will be developed or updated to be compliant with current regulatory requirements under REACH (e.g. ECHA’s Practical guide 5 - “How to use and report (Q)SARs” and ECHA´s “Read-across assessment framework (RAAF)”), focusing on providing all the information needed to evaluate and use the obtained results (e.g. QMRF and QPRF). The organisation of international workshops as well as targeted webinars for stakeholders (e.g. regulators and representatives of chemical industries) will establish a productive stream of information between the potential end users and the beneficiaries involved in the project, improving the usability and relevance of the newly developed software solution. **References** [1] LIFE CONCERT REACH - Concerting experimental data and in silico models for REACH; project reference LIFE17 GIE/IT/000461; http://ec.europa.eu/environment/life/project/Projects/index.cfm?fuseaction=search.dspPage&n_proj_id=6791. MO062

Alternative approaches: how Firmenich has used the 3Rs to reduce the number of fish for REACH submissions

S. Gimeno, Firmenich / Legal and Compliance; J. Cena, Firmenich SA / Global Regulatory Services; D. Carson, Blue Frog Scientific Limited; P. REMUZAT, CEHTRA SAS; P. Thomas, CEHTRA SAS / Ecotoxicology and Risk Assessment

Firmenich registered ~100 substances as lead (or technical) registrant, with more than 1/2 of the substances in tonnage band 1 (1-10 tpa), 1/4 in tonnage band 2 (10-100tpa), 1/10 in tonnage band 2 (10-100tpa), and one substance in tonnage band 4 (>100tpa). Around 1/2 of the substances were mono-constituents, 1/3 multi-constituents and 1/4 UVCBs. To complete the information requirements, almost 2000 data points were required of which 1/3 were fulfilled using experimental values (studies conducted) and the rest with alternative approaches, i.e. waiving applying the relevant specific (Column 2 of Annexes VII to X), or general rules as stipulated in Annex XI. When applying general rules, (Q)SARs, *in vitro* methods, weight of evidence and grouping approach were considered, following the relevant ECHA Guidance and criteria for acceptance. In order to fulfill the information requirements for fish acute toxicity, 31 fish acute toxicity tests were conducted (OECD 203), while in 15 cases alternative approaches (mainly (Q)SARs) were used. ECOSAR as well as ISafeRat® models were used alone or in combination. On 2 occasions (Q)SARs were used to predict the fish acute toxicity of the transformation products. Regarding fish chronic toxicity, one early-life stage test (OECD 210) was completed in 2003 and the OECD 212 was used as alternative for technical reasons to derive a surrogate EC10, while this endpoint was waived in 10 cases and in one case the NOEC was predicted using iSafeRat®. No fish bioconcentration test (OECD 305) was conducted for the purposes of REACH dossiers, however available fish bioconcentration data or predictions were submitted in 30 cases. 1/3 of the data were existing bioconcentration tests results, while the remaining data gaps were filled with BCF predictions, when it was felt that this was appropriate. Various models were used, alone or in combination (BCF/BAFWIN, OASIS BCF Baseline model). QSARs were also used, mostly as WoE to waive and support existing studies (especially when fish data were required; When generating new information, and also to determine WAFs Lethal loading rates for mixtures to determine worst case toxicity using the iSafeRat® model as animal tests were performed as a last resort. Overall, it can be concluded that by applying alternative approaches for fish tests, we were able to reduce the use of fish by ~5000, while maintaining a high level of confidence in the hazard and safety assessments.

MO063

An MOA-consensus classification in the EnviroTox database

A. Kienzler, European. Commission - Joint Research Centre / Chemical Safety and Alternative Methods; M.G. Barron, U.S. Environmental Protection Agency / Gulf Ecology Division; M.A. Bonnell, Environment and Climate Change Canada / Ecological Assessment Division; K.A. Connors, Procter & Gamble Company / Environmental Stewardship and Sustainability Organization; C. Inglis, Environment and Climate Change Canada / Ecological Assessment Division; T.J. Norberg-King, U.S. Environmental Protection Agency / NHEERL/Mid-Continent Ecology Division; T. Martin, U.S. EPA; H. Sanderson, Aarhus University / Environmental Science; N. Vallotton, Dow Europe GmbH / Toxicology Environmental Research and Consulting; P.W. Wilson, Sanofi U.S., Inc. / Health, Safety and Environment; M.R. Embry, Health and Environmental Sciences Institute (HESI)

In the last decade, several mode of action (MOA) frameworks have been developed in aquatic ecotoxicology, mainly based on fish toxicity or associated with acute fish toxicity predictions. They provide information on a key determinant of chemical toxicity, but definitions of MOA used are unique to each of the classification schemes, therefore they lack harmonization and can give contradictory results. As a result, although the existing MOA frameworks have great potential to improve risk assessment and strengthen the use of alternative methods, a single reliable tool for MOA assignment still eludes ecotoxicology. The EnviroTox database contains curated *in vivo* aquatic toxicity results relevant for ecological risk assessments and contains a total of 91,217 records representing 1,563 species, and 4,016 chemicals. The database also includes information such as chemicals’ physico-chemical properties or MOA classification according to the Verhaar (modifed) framework, ASTER, USEPA TEST, and LMC OASIS fish toxicity models. Additionally, USEPA New Chemical and ECOSAR chemical category information has been added to provide information on structure-based grouping potential. The objective of this study was to critically evaluate this dataset with the aim of developing a ‘consensus’ MOA assignment for each chemical. A set of consensus rules was proposed based on a four model MOA comparison undertaken for the substances in the EnviroTox Database. A consensus was sought so that binary decisions could be made to classify those chemicals as non-specifically acting (i.e., narcotic), specifically acting or non-classifiable. In addition, a confidence rank was assigned to each MOA designation based on the degree of model consensus. This provides users of the EnviroTox database a transparent understanding of the variation between MOA classification schemes. In terms of regulatory relevance, an understanding of MOA, even at a simple binary level, can provide information that can infer chemical potency which can be useful for the prioritization (ranking) and risk assessment of chemicals. Here we present the results from the consensus MOA classification of 3900 organic chemicals according to the 3 classification categories described above: 40 and 17% of the chemicals are classified as Narcotics and Specifically acting chemicals respectively, whereas 43% cannot be classified. For 54% of the chemicals, the consensus MOA can be regarded as quite robust (medium to high confidence).

MO064

Application of Daphnia magna in toxicity assessment and detection of waterborne pathogens

V. Le, Chonbuk National University / Bioprocess Engineering; J. Min, Chonbuk National University / Department of Bioprocess Engineering; Y. Kim, Chungbuk National University / School of Biological Sciences

In this study, double staining method using two fluorescent dyes, Calcein AM and Propidium Iodide, was applied on *Daphnia magna* exposed to *Salmonella spp.* and *Shigella spp.* to assess their toxicity. Results showed that these bacteria caused disparate infectious ability on *daphnia* depending on age of this organism, bacteria concentration and exposure time. In detailed, *S. dublin* and *S. sonnei* are the most harmful strains to *daphnia*. Interestingly, older daphnia can give responses to nearly 10 CFU/ml of some bacteria strains. Besides, the proteomic profile of the treated *D. magna* was investigated using 2-dimensional gel electrophoresis method and then analyzed by the Progenesis software to explore the differentially expressed proteins (DEPs). The identified DEPs is involved in energy metabolism, oxidative stress response and dynamic structure of cytoskeleton filaments. The systematic approach to the analysis of proteomic responses used as well as the detailed analysis results has been useful in understanding the novel molecular mechanisms for pathogen induced pathological changes.Moreover, special DEPs can be used as novel sensitive biomarkers to detect these pathogens. Acknowledgment:\nThis work was carried out with the support of “Cooperative Research Program for Agriculture Science & Technology Development (Project No:PJ01267701)’ Rural Development Administration, Republic of Korea.

Automated, high-throughput measurement of size and growth curves of small organisms in well plates
J. Duckworth, Environment Department University of York; T. Jager, DEBtox Research / Dept of Theoretical Biology; R. Ashauer, University of York / Environment
Organism size and growth curves are important biological characteristics. Current methods to measure organism size, and in particular growth curves, are often resource intensive because they involve many manual steps. Here we demonstrate a method for automated, high-throughput measurements of size and growth in individual aquatic invertebrates kept in microtiter well-plates. We use a spheroid counter (Cell^{3}iMager, cc-5000) to automatically measure size of seven different freshwater invertebrate species. Further, we generated calibration curves (linear regressions, all p< 0.0001, r^2>=0.9 for *Ceriodaphnoa dubia, Asellus aquaticus, Daphnia magna, Daphnia pulex;* r^2>=0.8 for *Hyalella azteca, Chironomus spec.* larvae and *Culex spec.* larvae) to convert size measured on the spheroid counter to traditional, microscope based, length measurements, which follow the longest orientation of the body. Finally, we demonstrate semi-automated measurement of growth curves of individual daphnids (*C. dubia* and *D. magna*) over time and find that the quality of individual growth curves varies, partly due to methodological reasons. Nevertheless, this novel method could be adopted to other species and represents a step change in experimental throughput for measuring organisms' shape, size and growth curves. It is also a significant qualitative improvement by enabling high-throughput assessment of inter-individual variation of growth.

MO066
Comparative toxicity of 20 nm Silver Nanoparticles (AgNP) and TiO2 Nanoparticles (TiO2NP) using CaCo2 cells
E.J. Pool, O. David, University of The Western Cape / Medical Bioscience
Previous studies done by us indicated that AgNP at concentrations less or equal to 30 μg/ml were not cytotoxic nor inflammatory when exposed to human whole blood cultures (Kim L Lategan, Chavon R Walters, Edmund J Pool, 2019, The effects of silver nanoparticles on RAW 264.7 macrophages and human whole blood cell cultures, Frontiers In Bioscience Landmark Edition, 24, 347-365).The current study investigated whether CaCo2 human colon epithelial cells reacted similarly to AgNP, and to compare the relative toxicity of AgNP and TiO_2NP for these epithelial cells. CaCO2 cells were exposed to various concentrations of AgNP and TiO_2NP after which cell viability, and the secretory inflammatory biomarkers nitric oxide (NO), interleukin-6 (IL-6), interleukin-8 (IL-8) and macrophage migration inhibitory factor (MIF) levels were monitored. Cell viability was assessed using the XTT assay, NO using the Griess assay, and IL-6, IL-8 and MIF using commercially available DAS-ELISAs. Results obtained showed that AgNP is highly cytotoxic for CaCo2 cells (IC50 = 21 μg/ml). This study also showed that AgNP at 25 μg/ml had major modulatory effects on NO, IL-6, IL-8 and MIF secretion by CaCo2. On the other hand, TiO_2NP had only minor effects on cell viability, IL-6 and IL-8 at 250 μg/ml. Only NO and MIFsynthesis by CaCo2 were affected by concentrations of TiO_2NP below 250 μg/ml. In conclusion the current results show that AgNP has a major impact on CaCo2 cells at concentrations below 25 μg/ml. This is very different from our previously published data for AgNP using whole blood cultures. This indicate that there are differences in the adverse effects posed by the same size of AgNP for various cell types. On the other hand, TiO_2NP only had effects on CaCo2 cells at much higher concentrations. This indicate that TiO_2NP is less toxic than AgNP for CaCo2 cells. We suggest that future studies monitoring toxic effects of a specific nanoparticle should use a panel of cell lines or primary cells to get a wholistic view of adverse effects that may be caused by the nanoparticles.

MO067
Comparison of metabolism of fragrance chemicals in rainbow trout liver S9 sub-cellular fractions and in the invertebrate Hyalella azteca
H. Laue, Givaudan Schweiz AG / Fragrances S & T; L. Hostettler, R. Badertscher, Y. Weiner-Sekiya, Givaudan Schweiz AG; I. Bischof, Fraunhofer Institute for Molecular Biology and Applied Ecology IME; C. Schlechtriem, Fraunhofer IME / Department Bioaccumulation and Animal Metabolism; G. Sanders, Givaudan International SA / Regulatory Affairs and Product Safety; A. Natsch, Givaudan Schweiz AG / Fragrances S &T
Bioaccumulation in aquatic species is a critical endpoint in the regulatory assessment of chemicals which usually involves the determination of the bioconcentration factor (BCF) in fish. Two assays measuring *in vitro* intrinsic clearance rates of chemicals have been recently adopted as new OECD test guidelines (TGs) using hepatocytes or liver S9 sub-cellular fractions from rainbow trout to refine BCF predictions. Bioconcentration studies in the invertebrate *Hyalella azteca* had been recently proposed as an alternative non-vertebrate *in vivo* screening assay. One of the major uncertainties using an invertebrate as a surrogate for fish bioaccumulation may be encountered due to a different and limited metabolic capability compared to vertebrates. The goal of this study was to compare the metabolites formed for 3 different fragrance chemicals in rainbow trout assessed by the RT-S9 *in vitro* assay and in parallel *H. azteca*. BCF studies were performed with 3 different fragrance chemicals in a flow-through system with *H. azteca*. Concentrations of the parent chemicals in water and in the animal were determined by GC-MS analysis. Additional samples were prepared from exposed animals at two time points during the exposure phase for metabolite identification. Substrate depletion assays for the same chemicals were performed using RT-S9 following the new OECD TG319B. All samples were purified by SPE and metabolites determined using GC-MS and LC-MS-analysis. For all 3 fragrance chemicals hydroxylations as Phase I reactions followed by the formation of Phase II conjugates were observed both for RT-S9 and *H. azteca*. However, different kinds of Phase II conjugates were found for the two organisms. In RT-S9 conjugates with glucuronic acid were identified as major Phase II metabolites, whereas in *H. azteca* glucose conjugates were detected. Additionally, conjugates with sulfate or sulfate plus glucose were found in the invertebrate. Interestingly, a different preference in biotransformation for the different isomers of one of the fragrance chemicals was observed in *H. azteca* compared to RT-S9. Comparable metabolic routes, i.e. hydroxylation of hydrophobic chemicals followed by conjugation reactions using glucuronic acid or glucose and sulfate were observed for 3 fragrance chemicals in rainbow trout assessed in RT-S9 and in *H. azteca* indicating a high metabolic capacity which may render this invertebrate a suitable model for BCF studies as a novel screening approach.

Stoddart, PETA International Science Consortium Ltd.
The assessment of aquatic toxicity is required in various regulatory frameworks and has a huge impact on the number of fish used in testing. The acute fish toxicity test (OECD Test Guideline [TG] 203), which uses lethality as the endpoint, is one of the most frequently used aquatic toxicity tests. This represents a very significant animal welfare concern. Moreover, while knowledge on the scientific limitations of individual fish tests in terms of reproducibility and relevance to environmental protection is growing, new scientifically advanced methods are enriching the toxicology toolbox. Thus, advanced Integrated Approaches to Testing and Assessment (IATA) for acute aquatic toxicity are of high social, environmental and scientific interest. IATAs may structure and guide combining mechanistic information from the molecular and cellular level such as from the RTgill-W1 cell line assay, information from *Daphnia* and algae as species of lower trophic levels and the Acute Fish Embryo Toxicity Test (FET, OECD TG 236) as refinement method. Through the OECD Test Guidelines Programme, Austria and the International Council on Animal Protection in OECD Programmes are working with leading experts and the OECD VMG-Eco, to develop such IATAs. The related OECD project aims to enrich the Threshold Approach for Acute Aquatic Toxicity Testing (OECD Guidance Document 126) with new toxicological tools, including computational approaches. Progress towards the development of IATAs will be discussed and one potential IATA will be outlined: Briefly, this IATA first considers all available data (e.g. physicochemical properties, mammalian toxicology, neurotoxicity and metabolism), data on the mechanism of action and from algae and *Daphnia* testing (OECD TGs 201 and 202). Facultative tiers may include *in silico* predictions for algae and *Daphnia* EC_{50} and for fish LC_{50}, experimental data from *in vitro* tests such as a cytotoxicity assays using fish gill cell lines, and the FET test. Mechanism of action information will inform the method selection within the IATA. No further testing is required once the fish EC/LC_{50} can be predicted or it can be concluded that algae or *Daphnia* are more sensitive than fish (embryos, cell lines). Testing according to TG 203 should only be performed as a last resort. *The views, conclusions and recommendations are those of the authors and do not necessarily represent the policies or positions of the organisations to which they are affiliated.*

MO069
Development of a rapid agar-based algae growth inhibition screening test
I. Pimparel, AquaBioTech Group; T. Teixeira, AquaBioTech Group / Research and Development; s. larroze, AquaBioTech Group
The OECD guideline 201 "Alga, growth inhibition test" is routinely used in aquatic ecotoxicology to assess the toxicity of chemicals on phytoplanktonic species. The test is performed in liquid test medium incubated under controlled conditions for 72 hours. Range finding tests are usually performed to find the concentration range in which effects are likely to occur in order to subsequently

define the concentration of test substance inducing 50% reduction of growth (EC50). The present study aimed to apply rapid and cheap methods to assess algal growth inhibition that can be used as preliminary range finding test or as screening method during the chemical development phase. Algae or diatom cells are transferred from an exponentially growing liquid culture and inoculated in agar plates. Three methods are to be tested in order to choose the most appropriate one. A spotting assay consisting in transferring the test item to the inoculated plate with an inoculation loop. A paper disk approach where a 6mm filter disk with the desired test concentrations is applied in the inoculated agar plate. An agar well diffusion method using a cork borer to puncture a 6mm hole where 20-100 mL of test solution are going to be introduced. All plates were incubated facing up at 20°C to a continuous light exposure. Growth inhibition was monitored over 4 days and evaluated by the presence and/or absence of a radius of growth of inhibition (mm). The methods were used with the marine diatoms *Phaeodactylum tricornutum* and *Thalassiosira pseudonana* the marine green microalgae *Tetraselmis chuii.* Results were compared with data obtained from the standard method (OECD 201). The method was used with the reference item 3,5-dichlorophenol and nanomaterials. The agar-based method is less labour intensive compared to the liquid method and can be adapted for freshwater algae species. We suggest it can be used as screening and/or range finding test in aquatic toxicity studies. **Acknowledgements**: This research is supported by the project SMARTAQUA that is funded through the MarTERA cofound partners Foundation for Science and Technology Portugal (FCT), Research Council of Norway (RCN) and Malta Ministry for Education and Employment (MCST)

MO070

Dioxin and AhR impairs cardiac development via direct regulation of key mesoderm genes in human embryonic stem cells

H. Fu, Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences; L. Wang, State Key Laboratory of Cardiovascular Disease, Fuwai Hospital, National Center for Cardiovascular Diseases, CAMS&PUMC, Beijing, China; J. Wang, B. Bennett, G. Hu, Epigenetics and Stem Cell Biology Laboratory, National Institute of Environmental Health Sciences, NC, US; B. Zhao, RCEES, CAS

Dioxin and dioxin-related polychlorinated biphenyls are potent toxicants with association with developmental heart defects and congenital heart diseases. However, the underlying mechanism of their developmental toxicity is not fully understood. Further, different animals show distinct susceptibility and phenotypes after exposure, suggesting possible species-specific effects. Using a human embryonic stem cell (ESC) cardiomyocyte differentiation model, we examined the impact, susceptible window, and dosage of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) on human cardiac development. We showed that treatment of human ESCs with TCDD at the ESC stage inhibits cardiomyocyte differentiation, and the effect is largely mediated by the aryl hydrocarbon receptor (AHR). We further identified genes that are differentially expressed after TCDD treatment by RNA-sequencing, and genomic regions that are occupied by AHR by chromatin immunoprecipitation and high-throughput sequencing. Our results support the model that TCDD impairs human ESC cardiac differentiation by promoting AHR binding and repression of key mesoderm genes. More importantly, our study demonstrates the toxicity of dioxin in human embryonic development and uncovered a novel mechanism by which AHR regulates lineage commitment of ESC. It also illustrates the power of ESC-based models in the systematic study of developmental toxicology.

EcoToxChip: A toxicogenomics tool for chemical prioritization and environmental management

N. Basu, McGill University / Faculty of Agricultural and Environmental Sciences; D. Crump, Environment and Climate Change Canada / National Wildlife Research Centre; M. Hecker, University of Saskatchewan / School of the Environment & Sustainability and Toxicology Centre; J. Head, McGill University / Natural Resource Sciences; J. Xia, McGill University; N.S. Hogan, University of Saskatchewan / Department of Animal and Poultry Science and Toxicology Centre; G. Hickey, McGill University - Macdonald Campus / Natural Resource Sciences; S. Maguire, McGill University / Desautels Faculty of Management

Here we provide an overview of our Large-Scale Applied Research Program (LSARP) grant from Genome Canada that aims to develop, test, validate, and commercialize quantitative PCR arrays (EcoToxChips) and a data evaluation tool (EcoToxXplorer.ca) for the characterization, prioritization, and management of environmental chemicals and complex mixtures of regulatory concern. In Project Phase 1, EcoToxChips are being developed for laboratory model species representing the most important vertebrate groups in ecological risk assessment (fish-fathead minnow; bird-Japanese quail; amphibian-*Xenopus laevis*). Model species (adult and early-life stage, ELS) are being exposed via standardized tests to 8 environmental chemicals representative of natural resource/environment sectors of Canadian concern and also ones that impact a wide biological space (EE2, chlorpyrifos, benzo(a)pyrene, lead, fluoxetine, selenomethionine, trenbolone, HBCD) (Activity 1). An integrative systems approach based on functional 'omics (combined global transcriptomic and proteomic profiling, targeted metabolome) and physiological analyses across levels of biological organization is being applied to characterize relevant toxicity pathways including adverse outcome pathways, AOPs (Activity 2); from this, and other resources, species-specific EcoToxChips consisting of 384 environmentally-responsive genes of regulatory concern are being informed, built, tested, and optimized (Activity 3). EcoToxChip performance will be validated (and further optimized) through an inter-lab study with our collaborators (Activity 4). Under Activities 5-7, knowledge from Phase 1 is being translated to 3 native species (i.e., fish: rainbow trout; bird: double-crested cormorant; amphibian: Northern leopard frog). EcoToxXplorer.ca provides intuitive bioinformatics support and be modeled on our successful cloud-based tools (metaboanalyst.ca). To position the team advantageously with regard to the commercialization and institutionalization of the deliverables, our GE3LS research will produce and leverage social science knowledge about the phenomenon of "institutional entrepreneurship". The anticipated socioeconomic benefits associated with the adoption of our deliverables, namely more focused animal testing, improved regulatory decision-making, and cost-efficiencies. Here we provide a 30 month update of our project (www.ecotoxchip.ca).

MO072

Effects of PCB 28, PCB 52 and PCB 118 on Primary Mantle and Gill Cell Cultures of Unio pictorum and Unio crassus

P. Arslan, Ankara University / Biology; B. Yurdakök-Dikmen, Ankara University / Department of pharmacology and toxicology; . KuzukÄran, Veterinary Control Research Institute; A. Filazi, Ankara University / Department of pharmacology and toxicology

Polychlorinated biphenyls (PCBs) are among persistant organic pollutants under Stockholm Convention.They are widespread and hazardous contaminants of environment.Eventhough, their production has been banned since 1970s, they are still used in some industrial areas (paints, etc.), transfer fluids, capasitor oils and pesticides.European Food Safety Authority reported six PCB congeners (PCB 28, 52, 101, 138, 153 and 180) as indicator PCBs in the environment.Also, some PCBs are categorized as dioxin-like PCB (such as PCB 118) which is monitored in the environment.PCBs are easily transferred in the air, water, soil which can be then moved by dust, snow or rain in areas eventhough they are not used such as arctic. In the end of this cycle, they are a part of aquatic environment via bioaccumulating and biomagnificating in aquatic organisms or deposition in sediment.Thus, their persistance in aquatic environment make them potential treat to wildlife and eventually lead human health concerns.Due to the fact that they are filter-feeded organisms, mussel contain more concentrated PCBs in their tissues than water. Although there are a lot of studies, either *in vitro* or *in vivo*, that marine mussel species are used as indicator species, few studies are available for freshwater mussel species.Therefore, the present study was aimed to determine cytotoxic effects of two indicator PCB (PCB 28 and PCB 52) and one dioxin-like PCB (PCB 118) on primary mantle and gill cell cultures of two freshwater species *Unio pictorum* and *Unio crassus* using MTT assay. *U. pictorum* were found to be more sensitive compared to *U. crassus* for the mantle tissue for all the tested PCBs with lower IC50 values; this relation was not observed for gill cells.PCB118, the highest chlorinated congener among the tested compounds, showed least toxicity; which could be attributed to its molecular size where small molecules were able to solubilize and enter the cell easier to induce their toxic effects.The most cytotoxic compound was PCB28 on *U.pictorum* gill with an IC50 of 0.13 ppb; while the least was PCB118 in *U.crassus* gill with an IC50 of 47.37 ppb.Species specific differences along with the environmental conditions that the cultures *Unio* species are taken influence the *in vitro* toxicity effects.Meanwhile, this study provides valuable information on freshwater mussel species and their responses to environmental pollutants in *in vitro* conditions. Keywords: *Unio pictorum, Unio crassus,* PCB, cytotoxicity

MO073

Effects of Zinc Pyrithione and Copper Pyrithione on Primary Mussel Cell Cultures

P. Arslan, Ankara University / Biology; B. Yurdakök-Dikmen, . ąahin, Ankara University / Department of pharmacology and toxicology; A.C. Gunal, Gazi University / Biology Education; A. Filazi, Ankara University / Department of pharmacology and toxicology; F. Erkoc, Gazi University / Biology Education

Antifouling paints are used against undesirable colonization of fouling organisms on natural and artifical surfaces; which impact economy by material loss and environment by spread of invasive species along with other undesirable health effects. Among the first used antifouling agent, tributyltin (TBT) was banned since 2008 due to its adverse effects on aquatic organisms and ecology. This resulted in the use of new alternative antifouling biocides such as zinc pyrithione (ZPT) and copper pyrithione (CPT). As these compounds in combination and alone, are still widely used, toxicity assays in the aquatic environment are needed for all possible affected species. As a freshwater mussel, *Unio crassus* Philipsson, 1788 (Bivalvia, Unionidae), is used as biological monitoring mollusc organism for freshwater ecosystems. Therefore, this study was aimed to determine the cytotoxic effects of ZPT, CPT (0,0008-3,125 µM) and their combination on primary gill and mantle cell cultures of *Unio crassus* using mitochondrial (MTT) and lysosomal (NR) cell viability assays.. According to results, ZPT were found to be more toxic than CPT. CPT alone application were found to be less cytotoxic compared to the combination where a decrease in IC_{50} of 90% and 81% (mantle and gill) were present for MTT assay. Both combination and alone applications indicate a cell death through mitochnondrial pathway compared to a lysosomal pathway. The results of study indicate that at nM concentrations, both zinc and copper pyrithrone have cytotoxic effects on the primary Unio mantle and gill cells; where the cytotoxicity increased by the combination of the tested drugs. Mantle and gill primary cultures provide useful biological monitoring tools to determine effects of environmental contaminants. Keywords: *Unio crassus*, cytotoxicity, zinc pyrithione, copper pyrithione

MO074
Endocrine disruptors screening analyzing zebrafish sperm quality
M.J. Mazón, BioBide; M. Ipiñazar, BBD BioPhenix S.L.; A. Muriana, BioBide / RD; A. Alday, BioBide
Endocrine disruptors (EDCs) are chemicals that by interfering with the endocrine system can have an adverse effect at developmental, neurological, immune and reproductive level. The negative impact of EDCs is becoming a real public health issue, therefore the necessity of tests to assess the potential risk of new chemicals before they are marketed is increasing. The zebrafish is currently used as a model for the evaluation of acute and developmental toxicity, and also for the screening and testing of potential endocrine disrupters as described in the OECD Guidelines. However, the two major endpoints used to evaluate endocrine disrupting chemicals, vitellogenin concentration and change in sex ratio, have several limitations. With the purpose of expanding the number of tests available to identify xenobiotics with endocrine disrupting activity, we developed an assay that evaluates the reproductive performance of zebrafish (after *in vivo* or *in vitro* exposure to EDCs) by measuring sperm quality using a computer-assisted sperm analysis (CASA). For *in vivo* experiments, adult zebrafish (aged between 6-12 months) were exposed to heavy metals (copper or mercury), herbicide (N-[phosphonomethyl] glycine) and bisphenol A for a period ranging 2-15 days. At the end of the exposure period the testes were excised, placed in tubes with immobilization solution and the sperm was released by gently shake. For *in vitro* experiments, sperm from untreated adult zebrafish was incubated for 30 to 240 min with four concentrations of copper, methyl mercury, N-[phosphonomethyl] glycine and bisphenol A. In both experiments, sperm quality (after activation with system water) was evaluated using a microscope with a negative-phase contrast objective connected to a computer-assisted sperm analysis (CASA) system (Proiser R + D, S.L.; Paterna, Spain). Parameters such as progressive motility, curvilinear velocity and linearity were evaluated and compared to DMSO treated control. The assay here proposed with these two *in vitro* and *in vivo* approaches, can discriminate between compounds with a direct cytotoxic effect (reducing sperm motility) and compounds that might generate, after long exposure, a reduction in fertility by disrupting the overall process of spermatogenesis.

MO075
Enhancing the utility of the Sequence Alignment to Predict Across Species Susceptibility tool
C. Finnegan, ORISE at US EPA; J.A. Doering, C. LaLone, U.S. Environmental Protection Agency / Mid Continent Ecology Division
The number of new chemicals introduced to commerce each year exceeds the practical ability to experimentally determine the consequences of those chemicals on all species that may be exposed. To address this challenge new approach methods are increasingly becoming important as supplementary evidence for chemical safety evaluations. A new approach method for predicting cross-species chemical susceptibility is the Sequence Alignment to Predict Across Species Susceptibility tool (SeqAPASS v3; https://seqapass.epa.gov/seqapass/). SeqAPASS is a web-based tool that allows the user to begin to understand how broadly toxicity information may plausibly be extrapolated across species, while describing the relative intrinsic susceptibility of different taxa to chemicals with known modes of action (e.g., pesticides, pharmaceuticals, other specifically acting chemicals). The tool rapidly and strategically assesses available molecular target information to describe protein sequence and structural similarity at the primary amino acid sequence, conserved domain(s), and individual amino acid residue levels. Development of the SeqAPASS tool is an iterative process making improvements by gathering information from users through training and outreach to identify new functionality and user-friendly features for implementation. Such features are anticipated to grow the user base and improve susceptible predictions. Recently the SeqAPASS development team has begun to integrate help menus and tools tips, as well as features for interoperability with other tools (e.g., ECOTOX Knowledgebase; https://cfpub.epa.gov/ecotox/) for the next release of SeqAPASS v4 anticipated for 2019. Additionally, it is critical to continue to continue to demonstrate the utility of the SeqAPASS tool in predicting cross-species chemical susceptibility. Therefore, a case study was developed considering cross-species susceptibility to diamide insecticides.

MO076
Evaluation of skin mucus vitellogenin (VTG) in a Japanese Medaka fish sexual development test (OECD TG 234) with 17beta-ethinylestradiol (EE2) as contribution to 3Rs animal welfare concept
S. Pawlowski, V. Strauss, BASF SE; E. Salinas, BASF SE / Eperimental Toxicology and Ecology; M. Braun, S. Groeters, S. Champ, B. van Ravenzwaay, BASF SE
Background: Vitellogenin is regarded as sensitive biomarker to detect exposure to endocrine active chemicals in fish and provides mechanistic mode-of-action information. The current OECD TGs 229, 234 and 240, recommend measuring VTG in the liver or head/tail homogenate of sacrificed fish. In the OECD TG 240 an extra cohort is used for whole body VTG measurement. VTG measurement in skin mucus of living fish is possible and may save individuals for other investigations. **Objective:** Implementing VTG measurement in skin mucous in an OECD TG 234 positive control study and comparison to established recommended procedures. **Methods:** The fish sexual development test was performed generally according to the OECD TG 234 with two replicates of 30 fertilized eggs each, in the control group and in the treatment group (0.1 μg/L EE2) in a flow-through system. Medaka fish (*Oryzias latipes*) were raised until day 60 post hatch. All recommended endpoints were measured. This poster focuses on secondary sex characteristics (stereomicroscopic investigation after modified Davidson's fixation of the dorsal and anal fin), genotypic sex ratio (dmy gene with PCR), VTG levels in skin mucus and head/tail homogenate (ELISA) and histological evaluation of gonads, liver, and kidney in the midsection cut after fixation in Davidson's solution. The VTG measurement in skin mucous, whole fish body and liver tissue had been validated in advance. **Results:** Whereas in the control group the phenotypic sex ratio was 58/42 % (male/female), in the EE2 group all fish were phenotypically females as confirmed by histologic investigation of the gonads. The genotypic sex ratio in the control group matched the phenotype and the genetic sex ratio in the EE2 group was not statistically different to the control. Female fish from the control and EE2 group could be differentiated from male controls by VTG levels in skin mucus as well as in head/tail homogenate. However, the coefficient of variation in each group was higher among the VTG in mucus compared to the head/tail VTG. **Conclusion:** Vitellogenin in skin mucus can be used as parameter especially for in interim measurements from living fish during the course of a study. However, the mucus sampling procedure should be further standardized to minimize variation and increase the power of this parameter.

MO077
Extending International Guidance to Relevant Middle Eastern Organisms: Acute Exposure of 4 Aromatic Hydrocarbons to Indigenous Marine Species Using a Passive Dosing Approach
J. Butler, ExxonMobil Biomedical Sciences, Inc / Environmental Toxicology and Chemistry Laboratory; L. Varghese, Brunel Oil & Gas; N. Deb, Brunel Oil & Gas / Environmental; B. Thornhill, NES Global Talent
The Arabian Gulf is a dynamic environment with unique habitats. The inhabitants of this marine ecosystem have been understudied and a lack of reliable data exists to benchmark their sensitivities against commonly used test organisms. Current testing guidelines do not reference relevant species for this region of the world. Recent efforts are underway to develop guideline extensions for relevant species from primary trophic levels. An Indigenous copepod, algae and juvenile killifish were selected as model test organisms to perform acute exposures of 1-Methylnaphthalene, Phenanthrene, Biphenyl and Octahydrophenanthrene. Test durations were 48, 72 and 96 hours and generally followed OECD 158, 201 and 203 respectively. To deliver and maintain controlled exposure concentrations, a passive dosing format consisting of silicone O-rings was employed. Critical Target Lipid Body Burdon's for similar species were used as inputs in The Target Lipid Model to select a range of 5 concentrations and subsequently benchmark sensitivity differences against other species currently recommended within international guidelines (i.e. OECD, ISO, EPA, etc.).

MO078
In vitro and in silico evaluation of antiproliferative activity and receptor binding affinity of newly synthesized succinimide derivatives
N. Milošević, M. Milanović, N. Milić, J. Ćurčić, University of Novi Sad, Faculty of Medicine / Department of Pharmacy; V. Kojić, D. Jakimov, University of Novi Sad, Oncology Institute of Vojvodina; J. Petković Cvetković, G. Ušćumlić, University of Belgrade, Faculty of Technology and Metallurgy
The succinimide moiety provides a pharmacophore for potential antiproliferative agents. Their potential affinity to bind to estrogen receptors may be important for their antiproliferative activity against estrogen positive cells as well as for their endocrine disrupting potential. The aim of this study was to determine in silico estrogen receptor binding affinity, in vitro antiproliferative effect against estrogen positive and estrogen depending cells of six newly synthesized succinimide derivatives and to find the possible in vitro-in silico association of their affinity toward estrogen receptors. Six newly synthesized compounds were evaluated for their in vitro antiproliferative activity toward cervix carcinoma (HeLa) and estrogen positive human breast carcinoma (MCF-7) cell lines. Standard MTT assay was applied to evaluate cytotoxic activities of the analyzed compounds after cells were exposed for 48 h. For each compound IC_{50} was calculated. Moreover, for each compound *Estrogen Receptor alpha* (logRBA) affinity (www.acdlabs.com) were calculated. Five compounds expressed antiproliferative power against HeLa. Introducing fluorine in the molecule in para position was followed by 20-fold increment of antiproliferative effect and decrement of IC_{50}.

However,substitution of fluorine with chlorine and bromine induced increment of IC_{50} against HeLa cells. Position change of a chlorine and bromine from para to meta nulled the cytotoxic effect of the molecules. In silico for all observed compounds was detected modest *Estrogen Receptor alpha* (logRBA) affinity which varied from 0.12 to 0.35. However, statistically significant parabolic association was obtained between in silico determined logRBA and IC_{50} against HeLa cells (r^2=0.98, p< 0.01). Only three compounds have demonstrated antiproliferative capacity against MCF-7 cell lines. Hence, there were not enough in vitro data about affinity towards estrogen positive carcinoma cells to support the in silico obtained results. Strong parabolic in vitro-in silico association of antiproliferative activity of newly synthesized succinimide derivatives against HeLa cells and their predicted estrogen binding affinity was determined. *Acknowledgment:* This work was performed within the framework of the research projects No. OI 172013, supported by the Ministry of Education, Science and Technological Development of Republic of Serbia.

MO079

In vitro test to detect the presence of neurotoxic compounds in water and sediment samples

A. Sobrino-Figueroa, Universidad Autonoma Metropolitana, Iztapalapa / Hidrobiology; A. Perez-Rojas, Universidad Autonoma Metropolitana Iztapalapa / Limnology and geology. D Laboratory. Department of Hydrobiology

In this work, an *in vitro* test for the detection of compounds with neurotoxic effects in water and sediment samples is proposed, since *in vitro* tests have been considered as an alternative to animal tests, in order to comply with the proposal of the 3 Rs (Replace, Refine and Reduce). In addition these techniques have the advantages of having a better control in the conditions in an experiment, reduce the ethical implications, and are of lower cost. In this study a method was developed using mollusc foot tissue (*Pteria sterna*), exposed to pollutants to evaluate the activity of the AchE enzyme, to detect the presence of compounds with neurotoxic effects. Tests were carried out with metals (Cd and Cu), surfactants (LAS) and pesticides (Dichlorvos and Cypermethrin), to evaluate the response of this test to these contaminants. The tissue homogenates were prepared with phosphate buffer (pH 7.2), then the homogenate was incubated with the xenobiotics for 30 min. Later the activity of the AchE enzyme was determined by the Ellman method (microplate). The results obtained with the pollutants were significantly different from the tests without pollutants. In the tests with cadmium (0.05, 0.1, 0.5 and 1.0 mg L^{-1}) the inhibition of Ache enzyme activity varied from 8.5%, to 22.4%. In the tests with detergents (0.05, 0.1, 0.5, 1 mg L^{-1}) from 11.5 to 32.7% and in the tests with pesticides (0.001, 0.005, 0.05, 0.5 mg L^{-1} from 23.8 to 86.5% in all cases the response of this *in vitro* test was according to the concentration of the xenobiotics tested.

MO080

Lipophilicity influence on estrogen binding affinity of newly synthesized succinimide derivatives

N. Milošević, N. Milic, M. Milanović, J. Ćurčić, University of Novi Sad, Faculty of Medicine / Department of Pharmacy; J. Petković Cvetković, G. Ušćumlić, University of Belgrade, Faculty of Technology and Metallurgy; N. Banjac, University of Belgrade, Faculty of Agriculture, Food Technology and Biochemistry

Design of new drug entities beside biological activity and defined pharmacokinetic properties, also should have low environmental especially low potential to disturb the normal endocrine system function. Lipophilicity is the key phisicochemical property which defines the half-life time in the environment and toxicity for biotic and abiotic environment. The aim of this study was to determine in silico estrogen receptor binding affinity as well as their lipophilicity by use of chromatographic methods for six newly synthesized succinimide derivatives and to observe the lipophilicity influence on their affinity toward estrogen receptors. RP TLC was used for study of the retention behavior of N-(3- or 4- substituted phenyl)-2-phenyl-succinimide derivatives. Precoated RP-18W/UV254 10×10 cm plates (Macherey-Nagel GmbH and Co., Düren, Germany) were used as stationary phase and binary water-acetone solutions with a varying volume fraction, φ (0.45-0.70) of organic solvent, were applied as the mobile phase. After development, the spots were detected at 254 nm with UV lamp and R_f values were measured. For each analyzed compound *Estrogen Receptor alpha* (logRBA) affinity (www.acdlabs.com) and ClogP were predicted. Retardation factor, R_M was calculated for each compound according to the equation: $R_M=\log(1/R_f-1)$. Furthermore, in the linear correlation of the R_M values versus φ, the chromatographic retention constant R_M^0, was obtained as extrapolated value to 0% point: $R_M=R_M^0+S\times\varphi$. Highly significant linear correlation between in silico determined ClogP and experimentally obtained retention constants R_M^0 (r^2=0.972; p< 0.001) as well as against slope, S (r^2=0.954; p< 0.001) was observed, respectively. Hence chromatographic parameters may be used as lipophilicity measure. Modest in silico *Estrogen Receptor alpha* (logRBA) affinity which varied from 0.12 to 0.35 was calculated for the analyzed compounds. Statistically significant linear correlation was obtained between logRBA and lipophilicity determined as R_M^0 (r^2=0.857; p< 0.01) and S (r^2=0.904; p< 0.01), respectively. Lipophilicity increment of newly synthesized succinimide derivatives may enhance affinity for estrogen receptor alpha and thus increase their potential to affect endocrine system functions. *Acknowledgment:* This work was performed within the framework of the research projects No. OI 172013, supported by the Ministry of Education, Science and Technological Development of Republic of Serbia.

MO081

Measuring oxidative stress in zebrafish cell lines via a novel in vitro assay

S. Lungu, SLU Uppsala / Biomedical Sciences and Veterinary Public Health; A. Oskarsson, SLU Dept Biomed Sci Vet Publ Health / Dept of Biomed Sci and Vet Publ Health; J. Lundqvist, Swedish University of Agricultural Sciences / Department of Biomedical Sciences and Veterinary Public Health

Establishing *in vitro* methods is considered a high priority, since most risk assessment relies on in *vivo* studies. The Swedish Research council - amongst other European institutions - is increasingly funding programs dedicated to 3R principles. Therefore, we started our project “toxicity pathways – a novel strategy to reduce and replace *in vivo* studies in fish”. It is the prescribed goal to establish a battery of stably transfected *D.rerio* cell lines in order to test for specific toxicity endpoints. The latter may then be used for omics-based high throughput applications, screening, and prioritizing of positives. First, transfection efficiency of commercially available transfection reagents (Mirus X2, LT1, 2020; Promega FHD, F6, Viafectamine, TransFast; Roche XHP; Invitrogen Lipofectamine 2000; Qiagen SuperFect, Effectene) were tested in Pac2, ZF4, and ZFL *D.rerio* cell lines. Most promising candidates (FHD for Pac2 and ZF4, XHP for ZFL) were selected for cell transfection in transient reporter gene assays. A Nrf2-sensitive pGL4-based firefly-luciferase expressing plasmid was co-transfected with a normalizing renilla-luciferase plasmid. Second, all three reporter lines were exposed for 24h to exponentially increasing concentrations (0.1, 1, 10, and 100 μM) of known oxidative stress inducing chemicals (tertButylquinone, peroxide, and sulforaphane). In parallel, cell-viability was scored using standardized MTS-assay. Dose-response relationships could be shown in all transiently transfected cell lines for tertButylquinone and sulforaphane. Concentrations of causing less than a 20% decrease in cell-viability were considered as non-cytotoxic and should be used in ongoing assays for receptor activation or inhibition. ZF4 and ZFL were prioritized for further use. Last, a panel of environmentally applied pesticides (diazinon, deltamethrin, atrazine, metazachlor, tertButhylazine, diuron) was used for 24 h exposure (6.25, 12.5, 25, 50, 100 μM) of Nrf2 transiently transfected cells, in order to test for the ecotoxicological applicability of the bioassay. Dose response relationships were shown for certain tested pesticides (metazachlor, deltamethrin, diazinon), proofing the robustness of the assay.

MO082

Prediction of Acute Ecotoxicity of Chemical Substances by Graph Theory Approach

M. Takada, AIST of Japan; B. Lin, National Institute of Advanced Industrial Science / Research Institute of Science for Safety and Sustaintability; A. Terada, M. Hosomi, TUAT of JAPAN

Prediction of ecotoxicity of chemical substances catches much more social concern again in recent years. Most of the conventional methods such as ECOSAR is clustering the chemical substances empirically from the structural information of chemical substances and then predicting the toxicity value by employing a logP involved linear regression model (QSAR formula). Besides this, most of the conventional methods are not appropriate for predicting the ecotoxicity of inorganic compounds. Due to the nature of empirical clustering, the prediction accuracy would not be improved even if new toxicity test data are added. In addition, the user will get puzzled in selecting the prediction result in the case of multiple QSAR formulas with a chemical substance. To overcome the flaws of the existing methods, we employed the big dataset of AIST-MeRAM ecotoxicity test data and the structural information of Maccs Keys that vectorize a chemical structure to the 166-bit binary information, applied the graph theory to the dataset and to investigate the self-clustering by various unsupervised machine learning methods. We finally developed a new method in which the acute toxicity of fish, daphnids, and algae can be predicted with good accuracy, while the LogP or linear regression model in existing methods were not further necessary. To confirm the prediction ability of the new method, cross-validation and comparison with the prediction results of ECOSAR was performed. The prediction ability is proved to be equivalent or better than that of the existing methods, and a wider variety of chemical substances could be coped. In addition, this new method is flexible to accepting toxicity test data and thereby the prediction accuracy could be improved.

MO083

Quality criteria for the development and application of (Q)SARs and further in silico methods in order to increase regulatory acceptance among various regulatory frameworks

I. Adaktylou, A. Gerloff-Elias, R. Gonella Diaza, knoell Germany GmbH

In order to meet data requirements for human and environmental safety assessment required by several chemical regulations, *in silico* methods pose an efficient alternative to traditional experimental testing, as they enable faster generation of data, help to avoid animal testing, and minimize costs as well as other resources. *In silico* methods describe computer-based calculation models

based on the hypothesis that similar structural features lead to similar effects or properties. They comprise several non-testing methodologies, such as (Q)SAR models, grouping approaches and expert systems. Just like experimental methods, *in silico* approaches have limitations in terms of areas of applicability. Indeed, (Q)SAR models are typically restricted in their applicability depending on the chemical frame, in which they have been developed, i.e. there is no "one model fits all" approach possible. In consequence, the evaluation whether a target molecule fits within the applicability domain of a (Q)SAR model, is a key aspect for assessing the reliability of a prediction. Although there is certainly, an increasing interest to use *in silico* methods on industry and regulatory bodies, acceptance of *in silico* predictions for regulatory hazard assessment is not guaranteed and users may rather prefer experimental testing as a safer choice. In order to improve standardization and harmonization of *in silico* methods and decrease the uncertainty for both regulatory bodies and industry, several guidance documents have been released in the last years in various regulatory frameworks [1, 2]. On the other hand, to date no criteria or guideline for the regulatory acceptance of (Q)SARs has been developed and guidance and instructions have not been adopted to a sufficient extent in every sector. This poster will address in more detail the current situation on quality criteria and acceptance of *in silico* methods for hazard assessment in different regulatory frameworks. It will furthermore describe what the different actors ((Q)SAR developers, authorities, regulatory bodies and industry) have to consider and improve in order to overcome the barriers of acceptance of computational assessment methods.

MO084
Skin sensitization assessment for agrochemicals - a suggested approach assessing the applicability of non-animal test methods/approaches and global acceptance
K. Fitzpatrick, Envigo Regulatory Consulting / Regulatory Consulting; R. Guest, Envigo Research Limited / In Vitri Technologies; A. Martins, Envigo Regulatory Consulting; D. Howes, Envigo Consulting Limited / Envigo Consulting Limited; J. Marchall, Envigo Regulatory Consulting / Regulatory Consulting
Non-animaltest methods/approaches for assessment of skin sensitization potential are available for chemical substances but can these be applied to agrochemicals and can a common global strategy be employed for their registration? For the recent REACH 2018 registration deadline for industrial chemicals, a non-animal test methods/approach was utilised. The availability of existing data for a weight-of-evidence assessment to determine testing strategy was firstly considered. *In silico* assessments of substances using (Q)SAR models to see if probability and/or alerts for skin sensitization are raised were also employed. *In chemico/in vitro* tests are required as an alternative to animal testing, addressing (where possible) key events 1, 2 & 3 of the skin sensitization Adverse Outcome Pathway (AOP). Currently, three non-animal OECD test guidelines are validated and regulatory-accepted for skin sensitisation assessment: *In Chemico* OECD 442C DPRA (key event 1) *In Vitro* OECD 442D either the ARE-Nrf2 Luciferase Assay (KeratinoSens™) or the ARE-Nrf2 luciferase LuSens test method (key event 2) *In Vitro* OECD 442E either the human cell line activation test (h-CLAT) or the U937 cell line activation Test (U-SENS™) or the Interleukin-8 Reporter Gene Assay (IL-8 Luc assay) (key event 3) *In vivo* testing (e.g. LLNA) may be performed from the start for some substances, but only if certain criteria apply. Moreover, testing *in chemico, in vitro or in vivo* may not need to be conducted in some circumstances. How do you know which criteria apply to your substances? In the flowchart we present a tiered approach to meet CLP classification requirements for your substance. We also review the results from applying the testing strategy to industrial chemicals for the REACH 2018 deadline and look at the concordance on acceptance of *in vitro* testing alternatives/approaches globally for agrochemicals.

Strategically Selecting Test Species using the Sequence Alignment to Predict Across Species Susceptibility (SeqAPASS) Tool
J.A. Doering, U.S. Environmental Protection Agency / Mid Continent Ecology Division; G.T. Ankley, U.S. EPA / National Health and Environmental Effects Research Laboratory; B.R. Blackwell, USEPA ORD / National Health and Environmental Effects Research Laboratory; K. Dean, Oak Ridge Institute for Science Education at US EPA; C. Finnegan, ORISE at US EPA; C. LaLone, U.S. EPA / Mid Continent Ecology Division; S. Poole, D.L. Villeneuve, U.S. EPA / National Health and Environmental Effects Research Laboratory
Chemicals in the environment can affect the health of wildlife with the potential for vastly different sensitivities among species. However, toxicity data used in risk assessment is based on a small number of model test species which might not represent the diversity of species sensitivities. This uncertainty is particularly true for many contaminants of emerging concern (CECs), including agonists of the peroxisome proliferator-activated receptor y (PPARy), for which species-sensitivity information might only be available for one or a couple species. However, performing toxicity testing for many species to determine the range in sensitivity is not practical. Therefore, the goal of this study was to demonstrate a means of selecting test species in a strategic fashion to determine the extent of differences in sensitivity by using the least number of species possible. Specifically, this study used the Sequence Alignment to Predict Across Species Susceptibility (SeqAPASS) tool to rapidly and computationally predict species-specific chemical susceptibility across phylogenetically diverse species through evaluation of structural similarities and differences in the protein target of a chemical. The public literature was used to identify 17 key amino acid residues in the ligand binding domain of PPARy that interact with chemicals, along with knowledge of amino acid differences that cause differences in binding affinity. Differences in these amino acids were investigated among sequences of 246 phylogenetically diverse species from the NCBI database using SeqAPASS. Four amino acid positions had differences across species that were predicted by SeqAPASS to potentially result in differences in binding of chemicals and therefore potentially result in differences in sensitivity among species. Five PPARy-types were proposed that likely differ in their sensitivity to agonists, namely Type 1 (mammals), Type 2 (birds, reptiles, amphibians, ancient fish), Type 3 (most fish), Type 4 (salmonids), and Type 5 (zebrafish). Based on these results, Xenopus (Type 2), fathead minnow (Type 3), rainbow trout (Type 4), and zebrafish (Type 5) were strategically selected as being representative of the diversity of species sensitivities to agonists of PPARy for ongoing investigation. This study demonstrates how SeqAPASS can be used to computationally predict species most likely to differ in sensitivity to chemicals for the strategic characterization of species differences in sensitivity.

Toxicogenomic analysis of Akaki river water using Caenorhabditis elegans
B. Sahilu, Addis Ababa University / Department of Medical Microbiology, Immunology and Parasitology; M.T. Zergaw, Addis Ababa University / College of Veternary medicine and Agricalture; N. Rai, Orebro University / The Life Science Centre,s School of Science and Technology; Y. Woldeamanuel, D. Asrat, Addis Ababa University / Department of Medical Microbiology Immunology and Parasitology; A. Mihret, A. Aseffa, Armauer Hansen Research Institute; P. Olsson, Orebro University / The Life Science Center-Biology; J. Jass, Orebro University / SCHOOL OF SCIENCE AND TECHNOLOGY
Deterioration of water quality is a threat to human and animal health worldwide. The problem is more overwhelming in developing countries where river water in urban regions serves as a final effluent point for industries and municipal discharge. Akaki river is the major river running through the center of Addis Ababa, Ethiopia and the downstream residents use the polluted river water for domestic and agricultural purposes. Previous studies of the Akaki river simply measured the levels of a limited number of individual pollutants. Toxicogenomic analysis using the *Caenorhabditis elegans* nematode offers an attractive model for measuring biological effect of the diverse pollutants.Water samples were collected from two sites in the Akaki river; MK (residential area) and BA (industrial area). Synchronized L1 *C. elegans* were exposed to the water samples or K-medium (control) until L4/young adult. The gene expression responses were evaluated by qPCR analysis of 30 genes associated with heat shock response, oxidative stress, innate immunity, metal response and development. Akaki river water induced a significant change in gene expression in exposed *C. elegans.* Although the levels of almost all analyzed metals and organic pollutants were below the permissible limit, the compiled effect resulted in transcriptional changes at the molecular level. Exposure to the waters led to an increased expression of *hsp-16.2*, *hsp-16.48*, *hsp-16.1*, *vit-6*, *daf-12*, *sod-1*, *tir-1*, *clec-60*, *tol-1 cyp-35A2* and *numr-1,* whereas the expression of sip-*1*, *lys-7, pgp-5*, *daf-16*, *lys-7, abf-2* and gst-*4* were significantly decreased compared to the control. A significant spatial variation was observed between the two sites in the expression of certain genes. The study demonstrated the usefulness of nematode based toxicogenomics analysis as an alternative tool to identify complex mixtures of pollutants and that Akaki river elicits a toxic effect on *C. elegans* at the molecular level.

Identification of chemicals of emerging concern using HRMS data: framework for suspect screening and effect-directed analysis
J. Meijer, T. Hamers, Vrije Universiteit Amsterdam / Department Environment & Health; R. Vermeulen, J. Vlaanderen, Utrecht University / Institute for Risk Assessment Sciences; M. Lamoree, Vrije Universiteit Amsterdam / Department Environment & Health
A generic framework is proposed to identify and prioritize emerging chemicals based on their exposure levels and toxicological profile for future regulatory and

screening efforts. This framework incorporates both suspects screening in untargeted high-resolution mass spectrometry (HRMS) data and effect-directed analysis (EDA). Untargeted mass spectrometry screening facilitates the measurement of thousands of small molecules in the environment and in human biological samples. Subsequently, a fast but putative identification can be acquired by comparing the accurate mass of a measured small molecules with the accurate mass of a known compound, an approach that is also embedded in effect-directed analysis. The first stage of the framework incorporates a database that contains accurate masses of >70.000 chemicals and their metabolites, this database can be used to putatively identify emerging chemicals in untargeted HRMS data, through a suspect screening approach. Further validation of putative matches can be done using newly developed bio-informatics tools, assessing MS/MS spectra, or using standards. Subsequently, in stage two of the framework their toxicological profile can be predicted based on their structure using computational tools (e.g. QSARs). EDA is a combination of biotesting, fractionation and chemical analysis and is used as a bottom-up approach where first the biological activity is characterized for different fractions of the sample. Subsequently, chemical analysis is performed on the bioactive fractions to identify the chemicals responsible for this activity. The method that will be used to measure bioactivity is the transthyretin (TTR) binding assay (TTR-FITC-T4 assay). This assay measures the interference of a chemical by competition with T4 in the binding to TTR which is important transport protein in the thyroid hormone system. Using a downscaled assay format in combination with increased fractionation resolution achieved by ultra-performance liquid chromatography (UPLC), high-throughput analysis of large numbers of samples is made possible. EDA will be done complementary to the suspect screening to identify those emerging chemicals that have a specific toxicological effect which were not primarily considered with suspect screening. The combined information about probability of presence in human samples and probability of toxicity will be used to rank emerging chemicals for prioritization in future human biomonitoring programs.

MO089

Identification of parent and TP compounds in waste water effluents by non-target analysis

F. Cappelli, IRSA-CNR / Department of Theoretical and Applied Sciences DiSTA; L. Triolo, EUROLAB SRL; S. Valsecchi, Water Research Institute - Italian National Research Council, IRSA-CNR; S. Polesello, Water Research Institute - Italian National Research Council, IRSA-CNR / Water Research Institute; I. Fochi, Thermo Fisher Scientific SpA; M. Peruzzo, EUROLAB SRL

The search of CECs in aquatic compartment has always been a run-up to the new emerging substance or "never studied before" class: from PPCPs to PFAS, nanomaterials and so on. Despite the immense number of chemicals in production and in use, our attention is still restricted to only a small number of well-known contaminants. However, are we sure that this target approach is correct to study chemical pollution and to protect environment? Isn't like focusing on the top of an iceberg and ignoring the hidden part? With innovative LC-HRMS instruments, and *full scan* analysis, one water sample measurement can return many thousands of signals that correspond to further molecules. One analytical run becomes a frame of the sample, because peak detection is not limited, but at the same time, it generates about 1 GB or more of data. Develop a model to prioritize peaks, simplify data elaboration and molecule name assignment, is the aim of the study. This non-target method was applied to wastewater samples, in particular to micropollutants characterised by persistence and formation during treatment plant processes, likely environmentally relevant.\n24-h composite samples were collected from a WWTP influent and effluent for 7 consecutive days. Water samples were filtered by glass fiber filter (0.7 μm) and extracted on OASIS HLB (Waters) cartridge. The initial LC-HRMS analyses were performed in full scan conditions (100-1000 m/z) with positive and negative electrospray ionization in separate runs. Different chromatographic gradient conditions were selected: methanol/ammonium formiate buffer for positive ESI mode and methanol/water and methanol/ammonium formiate buffer for negative ESI mode. Workflows for the prioritization and identification of the non-target peaks were carried out with Compound Discoverer 3.0 (ThermoFisher). A first prioritization was done after correction of the responses for matrix suppression by internal standards: RT alignment, blank subtraction, minimum peak intensity. Secondarily, the filtered compounds were analysed with the same chromatographic set up but with a data-dependent approach, to collect MS/MS information. Potential parent compounds and TPs in effluent samples were identified both using by suspect screening than by identity and similarity approaches.

MO090

Identification of organic pollutants and their transformation products in Upo wetland via target, suspect and nontarget screening using LC-HRMS

D. KANG, Department of FEED of Eco-Friendly Offshore Structure, Changwon National University; J. Jeon, School of Civil-Environment-Chemical Engineering, Changwon National University / School of Civil-Environment-Chemical Engineering

Diverse organic pollutants have occurred in natural water systems (e.g., wetland) and disrupted the aquatic ecosystem. Wetland would play a role as a melting pot of environmental pollutants promoting their degradation and elimination. Upo, the largest inland wetland in Korea, is mainly surrounded by agricultural area and so contaminated by diverse organic pollutants, especially pesticides. To extend our knowledge on contamination and decomposition functions of the wetland, major organic pollutants and their transformation products in Upo were traced by target, suspect, and non-target screening method using LC-HRMS. The wetland samples were collected at 8 different sites in November, 2017. As a result of first suspect and non-target screening to identify major pollutants, total 11 compounds were tentatively identified, including 8 fungicides (azoxystrobin, boscalid, carbendazim, cyprodinil, metalaxyl, methabenzthiazuron, tebuconazole, tricyclazole), 2 herbicides (atrazine, hexazinone) and 1 insecticide (thiacloprid). Among them, azoxystrobin, hexazinone, metalaxyl and tebuconazole were major pollutants in the wetland and confirmed by target analysis with reference standards. The median concentration of major pollutants was 46 ng/L for azoxystrobin, 55 ng/L for hexazinone, 220 ng/L for metalaxyl and 1,200 ng/L for tebuconazole. Some transformation products or metabolites such as azoxystrobin acid, metalaxyl acid, and 2-aminobenzimidazole were also tentatively identified. The peak intensity ratio of TPs to their parents gradually increased along with stream current direction of wetlands and greater up to 3 times at a downstream site. This suggests that the wetland water system serve as a degradation spot for organic pollutants. In future studies, quantitative analysis is needed for tentatively identified compounds in order to quantitatively evaluate the transformation kinetics and degradation capability of the wetland

MO091

Smart target method development for detection of antiviral compounds in aqueous environmental samples based on suspect screening and HRMS

B. Zonja, J. Guillen, IDAEA-CSIC / Environmental Chemistry; M. López de Alda, IDAEA-CSIC

Pharmaceuticals and other chemicals used worldwide are present in the environment because of the human impact. After a worldwide outbreak of swine influenza virus in 2009 antiviral drugs have been researched more intensively as environmental pollutants. But, antiviral drugs used for treatment of other viral infections like HIV, hepatitis or herpes could be equally significant since there are 2.1 million new HIV infections being reported (for 2015, source UNAIDS). This number has been in moderate decline over the last decades, however still today, over 36 million people worldwide are living with HIV. In the human body, they are only partially metabolised and, once excreted, they can reach the aquatic environment via WWTPs. As a result, they can end up in surface water together with the mixture of their human metabolites and transformation products which can form along the way. The aim of this work was to evaluate systematically their presence in the aquatic system. In order to avoid classical target method development which commonly relies on arbitrary selection of target compounds, here we used a suspect screening approach where a 100+ antivirals suspect list was matched to WWTP samples as a guarantee of environmental presence. This was especially advantageous since no data on drug consumption could be obtained. In our case, WWTP influent and effluent of the largest catalan WWTPs was sampled over three consecutive days. The samples were extracted using a generic SPE method and analysed using LC-QExactive-MS. Each positively detected exact mass was further rationalised with fragmentation patter study for a specific compound/structure. A list of antivirals identified and detected in all three consecutive days were considered important and were advanced to the target method development step. The list was joined with compounds that have been reported to occur in high concentrations in other publications in order to check whether non-detection was due to lack of presence of lack of selectivity. Additionally, recently marketed compounds were also added to the method since its consumption rates were expected to grow over time. Finally, target method was developed using SPE-high resolution LC-MS for fast and reliable quantification of forty antiviral compounds in the aquatic environmental samples.

MO092

Suspect and non-targeted strategies to investigate in vitro and in vivo biotransformation products of emerging environmental contaminants: the benzotriazoles and benzothiazoles

C. Baduel, CNRS IGE UMR 5001, Univ. Grenoble / The Institute for Geosciences and Environmental research; F. Lai, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; A. Van Nuijs, A. Covaci, University of Antwerp / Toxicological Center

Benzotriazoles (BTRs) and benzothiazoles (BTHs) derivatives are high production volume chemicals involved in a wide range of applications and consumer products. The widespread use of BTRs and BTHs and their occurrence in a wide range of environmental media (drinking water, indoor and outdoor air, indoor dust, textiles, etc.) as well as human urine samples across different countries suggest that the population is exposed continuously to these chemicals worldwide. However, while human exposure has been observed, exposure assessment to these chemicals is very limited and it is only based on the analysis of parent compounds in human specimens. The objective of this study was to investigate the *in vitro* human Phase I and Phase II biotransformation of six emerging contaminants (3 BTRs and 3 BTHs) through cytochrome P450 (CYP), uridine glucuronic acid transferase (UGT), and sulfotransferase (SULT). Highly used and ubiquitous BTRs and BTHs were selected as substrates in this present study. Moreover, they were considered as model compounds to predict potential biotransformation products of other BTRs and BTHs derivatives. Generated biotransformation products in the samples were investigated using liquid chromatography coupled to quadrupole-time-of-flight mass spectrometry (LC-QTOF-MS), followed by their identification and structural elucidation based on a workflow combining suspect and non-target strategies. Most of the proposed biotransformation products were identified and structurally elucidated for the first time and possible metabolic transformation pathways were presented for the studied compounds. The identified biotransformation products were then targeted for analysis in human urine samples. Our findings provide important insights for the selection of biomarkers in future biomonitoring studies and emphasize the importance to investigate the biotransformation products in order to assess overall exposure to xenobiotics.

MO093

Identification of chemical compounds enriched in the Baltic sea surface microlayer using targeted and non-targeted liquid chromatography mass spectrometry

J. Johansson, Stockholm University / The Department of Environmental Science & Analytical Chemistry (ACES); M. Salter, Stockholm University / Department of Environmental Science & Analytical Chemistry (ACES); O. Wurl, C. Stolle, T. Robinson, Carl von Ossietzky University Oldenburg / Center of Marine Sensors; I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry

The global oceans are known to be recipients of many pollutants but they can also act as a source of pollutants back to the atmosphere via sea spray aerosol (SSA). Although previous research has demonstrated that SSA is enriched in organic matter, a mechanistic understanding of what types of chemicals enrich in SSA is currently lacking. Results of our previous lab experiments suggest that enrichment in the sea surface microlayer (SML) is a good proxy for enrichment in SSA, although SSA enrichment factors (EFs) can be orders of magnitude larger than the corresponding SML EFs. Here, we use field samples to explore what types of biogenic and anthropogenic substances enrich in the SML. Eight paired bulk water and SML samples were collected in the Baltic Sea in June of 2018. Unfiltered samples were concentrated by a factor of 1000, using solid phase extraction. Analysis was performed by liquid chromatography high-resolution mass spectrometry on a Quadrupole-Orbitrap mass spectrometer. A targeted method was applied to determine SML EFs for a set of known environmental pollutants of low and high surface activity: pharmaceuticals and perfluoroalkyl acids. Additionally, a non-targeted screening method was applied to identify “unknown” chemicals which enrich in the SML. All samples were first analysed in fullscan mode. Peak areas were used to calculate SML EFs for each exact mass in each sample pair. A condition for the successful use of this data reduction approach is that any matrix effects are similar in both sample types (bulk water and SML). Analysis of spiked samples demonstrated that this was true for >95% of the test compounds. The screening detected 960 substances which had SML EFs >1.2. Of these, 680 substances were detected in positive ionisation mode and 280 in negative ionisation mode. After reanalysis in MS/MS mode, tentative identification via a mass spectral database was possible for 9 of the substances (>90% similarity). Further processing to achieve identification is currently performed on the 229 substances which had SML EFs >2. This involves scrutiny of fragmentation patterns, as well as using tools to identify homologue series. The structures of tentatively identified substances will be confirmed by comparison with chemical standards.

MO094

Development of an Ultrahigh Resolution Mass Spectrometry-Based Method for Nontarget and Suspect-Screening of Nitroaromatic Compounds in Atmospheric Particulate Matter (PM2.5)

S. Grebenyuk, Stockholm University, ACES / Department of Environmental Science and Analytical Chemistry (ACES); J.W. Martin, I. Sadiktsis, L.A. D'Agostino, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES and Science for Life Laboratory; . Gustafsson, K. Budhavant, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES and Bolin Centre for Climate Research

Air pollution is an environmental challenge in modern societies and a major cause of disease and premature death worldwide, with disproportionate consequences in developing countries. Ambient fine particulate matter ($PM_{2.5}$) and associated nitroaromatic compounds originate from combustion processes. Nitroaromatics are present in most atmospheric samples, are highly toxic and have a significant impact on climate forcing due to their light absorbing properties. Existing methods for monitoring of nitroaromatic compounds in the ambient atmosphere rely on targeted methods for specific compounds, but $PM_{2.5}$ is a complex mixture that is largely uncharacterized, thus here we developed and applied a method based on HPLC-ultrahigh resolution mass spectrometry. It was hypothesized that the highly diagnostic fragmentation and neutral loss behavior of nitroaromatics could be used to develop a comprehensive screening method for known and unknown compounds. Model compounds, including mono-nitroaromatics and poly-nitroaromatics (i.e. nitro-PAHs) were first analyzed to optimize analytical conditions. The optimal method was then applied to a series of $PM_{2.5}$ collected on quartz fiber filters during a campaign (SAPOEX18) in the Maldives between January and April 2018. Back trajectories were calculated for each sampling period using the Hysplit model, and 15 sample extracts were analyzed from three group defined by their geographical source regions: Bangladesh, India, and Arabian Sea. The nitroaromatic profiles will be discussed with respect to frequency of detection, meterological conditions, and geographic source.

MO095

Mass spectrometry-based analytical approaches to evaluate disinfection byproducts in chemically-disinfected water

C. Postigo, Institute of Environmental Assessment and Water Research IDAEA CSIC / Environmental Chemistry; A. Andersson, Linköping University; M. Harir, Helmholtz Zentrum Munchen; D. Bastviken, Linköping University; M. Gonsior, University of Maryland / Chesapeake Biological Laboratory; P. Schmitt-Kopplin, Helmholtz Zentrum Munchen; P. Gago-Ferrero, ICRA Catalan Institute for Water Research; L. Ahrens, Swedish University of Agricultural Sciences SLU / Dept. of Aquatic Sciences and Assessment; K. Wiberg, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment

Water disinfection is essential to prevent the spread of waterborne infectious diseases. However, the use of chemical desinfectants results in the unintended formation of disinfection byproducts (DBPs). The type of DBPs that get formed depends on the organic and inorganic precursors present in the water (e.g., type of natural organic matter, iodide, bromide content) and the disinfection conditions (e.g., type of disinfectant, dose, contact time, temperature, water pH). Some of these compounds are highly cytotoxic and genotoxic to mammalian cells, according to *in vitro* assays. Moreover, exposure to DBPs have been associated to an increased incidence of bladder cancer and the apperance of negative effets at developmental and reproductive level in various epidemiological studies. The present study aims at characterizing the changes in the natural organic matter of different source waters used to produce drinking water after disinfection at plant scale, and investigating the disinfection byproducts formed. For this, target, suspect and non-target screening approaches using low, high and ultra-high mass resolution techniques have been used. *Acknowledgments:* CP acknowledges support from the Swedish University of Agricultural Sciences through the August T Larsson Guest Researcher Programme.This work was supported by the Government of Catalonia (Consolidated Research Groups 2017 SGR 01404-Water and Soil Quality Unit)

MO096

Development of an GC-QTOF suspect and non-target screening method for the detection of organic contaminants in waste water

J. Riener, S. Lang, Agilent Technologies

Domestic waste water must be managed effectively to meet the challenges of increasing population, stringent regulatory requirements, and aging water treatment facilities. To meet these challenges, specific analytical methods are available to monitor chemical compounds in wastewater. However, because of the complexity of the sample matrix, several analytical methods are required to determine polar and non-polar organic compounds in the dissolved and suspended phases that may impact water quality. To screen for such a large and diverse suite of compounds, it requires non-discriminating sample preparation techniques and, ideally, universal detection techniques. A screening method in the combination of ultrasonic extraction, gas chromatography- high resolution mass spectrometry detection and automated feature extraction was developed for suspect and non-target screening in the sewage influent and treated effluent from an municipal wastewater treatment plant. The samples were extracted by ultrasonication for 20 min using dichloromethane for four times. The samples were analyzed by full scan GC/Q-TOF with a mid-column backflushing configuration and a 20 minute retention time locked (RTL) method. The results were evaluated using MassHunter software and the Agilent GC/Q-TOF Pesticides & Environmental Pollutants PCDL library for suspect screening . The non-target screening was performed using deconvolution with identification of the cleaned high resolution spectra using the NIST 2017 library. The identified pollutants included the Environmental Protection Agency (EPA) priority pollutants, pharmaceuticals, herbicides, antioxidants, intermediates, organic solvents and chemical raw materials. The proposed method is proved to be a promising one for non-target screening of complex matrix samples with the advantages of higher sensitivity and better repeatability.

MO097

Analysis of micropollutants and metabolites in Hwapo wetland via target, suspect and non-target screening using LC-HRMS

K.K. Kahilainen, Inland Norway University of Applied Sciences; J. Jeon, School of Civil-Environment-Chemical Engineering, Changwon National University / School of Civil-Environment-Chemical Engineering

Hwapo, the biggest riverine wetland in Korea is flowing into the Nakdong river used as a drinking water source and is a habitat living about 800 species. However, the wetland is surrounded by agricultural, residential and industrial areas and thus is contaminated by various organic pollutants. This study is aimed to identify major organic contaminants in Hwapo wetland via target screening, and to tentatively identify their transformation products(TPs) via suspect and non-target screening using HPLC-HRMS. Water samples were collected from 5 inlet streams and 7 spots of main stream of the wetland in July and August, 2018. The collected samples were pretreated with SPE method using multi-layer cartridge to enrich diverse substances having different physic-chemical properties. As a result of target screening, 12 pharmaceuticals(caffeine, niflumic acid, etc.) and 5 pesticides (carbendazim, oxadiazon, etc.) were quantitatively identified in both periods, and 4 pesticides were additionally detected only in July. Among them, caffeine(July: 33~1100 ng/L, August: 56~580 ng/L), niflumic acid(July: 23~75 ng/L, August: 42~290 ng/L), carbendazim(July: 10~110 ng/L, August: 64~520 ng/L) and oxadiazon(July: 17~220 ng/L, August: 66~460 ng/L) were detected at a relatively high concentrations in most sites and were considered to be the major contaminants. Through suspect and non-target screening, 10 substances(tebuconazole, hexaconazole, tricyclazole, diuron, simetryn, fexofenadine, irbesartan, cimetidine, valsartan, and benzotriazole) and 4 transformation products or metabolites (TEB_M324c, azoxystrobin acid, 2-aminobenzimidazole, and valsartan acid) were tentatively detected. When the parent compound and its metabolites were detected together, the peak intensity ratio of TP to the parent was calculated as an index for rate of degradation in the wetland. rate of degradation was confirmed by [(metabolite peak intensity / parent compound peak intensity) * 100 (%)] equation. The ratio for carbendazim(July: 0.36~3.2, August: 0.13~3.6) and valsartan(July: 0.13~2.8, August: 0.9~8.1) were relatively higher than tebuconazole(July: 0.08~0.26, August: 0.03~0.18) and azoxystrobin(July: 0.27~2.1, August: 0.12~0.58), and showed an increasing trend with increasing hydraulic retention time in the wetland. This result indicates that less organic pollutants are discharging into Nakdong river due to degradation processes taking place in the wetland.

MO098

Mass spectrometry in combination with in vitro bioassays: a tool for minimizing the exposure to toxic disinfection byproducts

M. Aznar-Luque, IDAEA-CSIC; C. Porte, IDAEA-CSIC / Department of Environmental Chemistry; C. Postigo, Institute of Environmental Assessment and Water Research IDAEA CSIC / Environmental Chemistry

Disinfection of water is a practice commonly used to ensure safety of drinking and reclaimed water. This practice results in the formation of a large suite of disinfection byproducts (DBPs) following the reaction of chemical disinfectants with organic and inorganic matter present in water. Many of these compounds have been reported to be highly genotoxic and cytotoxic in *in vitro* assays with Chinese hamster ovary (CHO) cells. Epidemiological studies have also associated their exposure with the appearance of negative effects at reproductive and developmental level, and even bladder cancer. Protection of public health calls for minimizing the formation of toxic DBPs in disinfected waters. This requires the development of analytical tools that allow identifying the most toxic DBPs in disinfected water so that appropriate measures can be adopted for minimizing them. The combination of mass spectrometry analysis and *in vitro* bioassays seems an appropriate tool to prioritize the study of toxic DBPs in disinfected water. Initial steps that should be taken in this direction are i) the evaluation of the toxicity response of the model cell line selected to individual DBPs and ii) the selection of a generic extraction protocol compatible with this bioassay that provides a representative DBP mixutre of the disinfected water. Due to the negative effects that DBPs may pose at developmental and reproductive levels, a human plancenta cell line (JEG-3) was selected to investigate their reprotoxic response. The generic extraction aproach will be selected evaluating the recovery of different DBP classes (iodinated trihalomethanes, trihalogenated haloacetaldehydes, halogenated acetonitriles, halogenated acetamides and haloacetic acids) with various extraction approaches (different SPE sorbents, liophylization). The present work summarizes the results obtained in these initial steps. *Acknowledgments:* C. Postigo acknowledges the financial support by Fundación General CSIC (Spanish ComFuturo Programme). This work was supported by the Government of Catalonia (Consolidated Research Groups 2017 SGR 01404- Water and Soil Quality Unit)

MO099

Effect-directed analysis of contaminants of emerging concern in hospital effluents

B. Gonzalez-Gaya, IMDEA Water (G84912732) / Environmental Chemistry; L. Mijangos, University of the Basque Country UPV/EHU / Department of Analytical Chemistry; M. Olivares, University of the Basque Country UPV/EHU / Plentzia Marine Station (PiE-UPV/EHU) & Dep Analytical Chemistry; A. Prieto, University of the Basque Country / Department of Analytical Chemistry; O. Zuloaga, N. Etxebarria, University of the Basque Country UPV/EHU / Plentzia Marine Station (PiE-UPV/EHU) & Dep Analytical Chemistry

The fate and distribution of new emerging contaminants and their unexpected effects in the environment are needed study topics, since most of the chemicals nowadays delivered in nature are unregulated and their effects are overlooked in many monitoring programs. These new chemicals include personal care products and pharmaceuticals (PCPPs) and consumption products (food additives, detergents, perfluoroalkyl substances, plasticizers, etc.). One of the main source points of those pollutants in aquatic ecosystems are wastewater treatment plants (WWTPs), which accumulate housing and industrial wastewaters and are not always able to degrade all these compounds. Then, they are delivered into rivers and marine waters with an unpredictable effect in the aquatic ecosystems. Within this context, an effect-directed analysis approach was implemented in the Galdakao Hospital WWTP effluents (Biscay, Spain). A large volume solid-phase extraction (LVSPE50) device was used on 35L of effluent water using a 6 g Chromabond HR-X (Macherey-Nagel), 2 g Sepra ZT-WAX (Phenomenex) and 2 g Sepra ZT-WCX (Phenomenex) sorbent combination. Afterwards, two fractionation steps were performed using C_{18} and aminopropyl chromatography columns. The fractions from the first separation step were tested with the available bioassays in order to look for the toxic fractions (i.e. in-vitro tests as YES/YAS and EROD). The identified as toxic were further fractionated and bio assayed a second time to restrict the identification of the toxic compounds. The recovery of the whole procedure (solid-phase extraction and fractionation) was assessed with a synthetic mixture containing over 200 standards. The non-targeted chemical analysis was run by liquid chromatography-high resolution mass spectrometer (LC-HRMS) using a Thermo Scientific Dionex UltiMate 3000 UHPLC coupled to a Thermo Scientific™ Q Exactive™ hybrid quadrupole-Orbitrap mass spectrometer with a heated ESI source (Thermo, CA, USA). The m/z values of the predicted compounds were searched in the peak list considering 5 ppm for mass tolerance and 30% for the intensity tolerance for the isotope search. Structural assignments were carried out based on $ddMS^2$ fragments annotated by Compound Discoverer 2.1 (Thermo-Fisher Scientific, CA, USA). Afterwards, we compared the exact mass, isotopic profile, fragmentation and abundances of the selected features with those available in the mzCloud (best match > 75 %) library.

Non-Target Characterization of Airborne Halogenated Organic Compounds by HPLC-HRMS

L. D'Agostino, Stockholm University, ACES / Chemistry; I. Sadiktsis, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES and Science for Life Laboratory; A. Andersson, K. Budhavant, . Gustafsson, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES and Bolin Centre for Climate Research; J.W. Martin, University of Alberta / Department of Environmental Science and Analytical Chemistry ACES and Science for Life Laboratory

A major mechanism by which persistent organic pollutants (POPs) become globally distributed is through long-range transport in the atmosphere. There are far more chemicals in commerce, and possible impurities and degradation products thereof, than are included in routine atmospheric monitoring. We hypothesized that unknown â_POP-like' halogenated contaminants are currently undergoing long-range atmospheric transport from today's major emission regions. With a large proportion of the world's population, a geographic shift of chemical production and use to China and India, and unregulated activities such as e-waste recycling by low temperature burning, Asia is an important source region that should be monitored by sensitive non-target analytical methods. The Maldives Climate Observatory at Hanimaadhoo (MCOH) is a large-footprint receptor for air transported long-range from regions of South Asia, including India and Bangladesh, thereby providing an opportunity for collection and nontarget analysis of persistent organic chemicals reaching this site in the Indian Ocean. A high volume air sampler was installed to collect fine airborne particulate matter (PM 2.5) on quartz fibre filters during 48-hour periods (700-1600 m^3) from January to April 2018 as part of the South Asian Pollution Experiment 2018 (SAPOEX-18) campaign. For some samples, semi-volatile organic compounds were simultaneously collected on downstream polyurethane foam plugs. Filters were sequentially extracted by sonication with a range of organic solvents to isolate a broad range of ionic, polar, and hydrophobic organic substances. Concentrated extracts were analysed by ultra-high performance liquid chromatography-high resolution Orbitrap mass spectrometry using data independent MS/MS. Methods for identifying halogenated features in the complex mass spectra were developed and implemented, based on isomer patterns of chlorine and bromine, characteristic fragment ions or neutral losses, and homologous series. Results show numerous features in PM 2.5 and PUF extracts with characteristic halogen signatures. For example, PM 2.5 contained a range of species with the general formula $C_7H_{6-n}X_nO_4$ (n = 1-2, X = Cl, Br, and/or I), and structural elucidation suggested these may be halogenated dihydroxy benzoic acids. New chemicals will be discussed with respect to their temporal variation throughout the campaign, and their regional sources by back trajectory analysis.

MO101

Human biomonitoring of a non-occupationally exposed population living near a hazardous waste incinerator: Temporal trends of PCDD/Fs in plasma

M. Marques, M. Mari, Universitat Rovira i Virgili / Chemical Engineering; M. Nadal, Universitat Rovira i Virgili / School of Medicine, IISPV; M. Schuhmacher, Universitat Rovira i Virgili / Chemical Engineering; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health

In 2018, the occurrence of polychlorinated dibenzo-*p*-dioxins and dibenzofurans (PCDD/Fs) in plasma from individuals living in the neighborhood of a hazardous waste incinerator (HWI) located in Constantí (Tarragona County, Spain) was assessed. Forty samples were collected from individuals of both genders, different age (19-69 years) and living in 2 areas of residence (urban and industrial).

Concentrations of PCDD/Fs were further compared to those already reported in the baseline study (1998), when the facility was still being built, and previous surveys (2002, 2007 and 2012), once the plant was already operative. In the current campaign (2018), the mean concentration of PCDD/Fs was 6.79 pg I-TEQ/g lipid, ranging from 0.23 to 32.7 pg I-TEF/g lipid. It meant a statistically significant reduction with respect to the baseline study (1998) as well as two previous campaigns (2002 and 2007), when mean PCDD/Fs levels in plasma were found to be 27.0, 15.7 and 9.4 pg I-TEQ/g lipid, respectively. However, current results were very similar to those previously reported in 2012 (6.18 pg I-TEQ/g lipid). When evaluating the PCDD/Fs congener profile, OCDD was the predominant congener, while 2,3,7,8-TCDD and 1,2,3,4,7,8,9-HpCDF presented the lowest levels. Anyhow, the individual concentration of most of the 17 PCDD/Fs congeners decreased over time. This reduction was actually reported in both genders, all group ages and residence areas, when considering the whole assessment period (1998-2018). In agreement with data from the scientific literature, a significant correlation between PCDD/Fs concentrations in plasma and age was observed. The current concentrations of PCDD/Fs in plasma of residents are in the lowest part of the range in comparison with results corresponding to other areas impacted by municipal or industrial solid waste incinerators. Hence, the human exposure to PCDD/Fs for the population living near the HWI located in Tarragona County does not mean any significant additional risk for the human health.

MO102

Investigation of metabolic changes in the freshwater amphipod Gammarus fossarum in response to sewage effluent exposure

D.R. Caputo, University of Portsmouth / Biological Sciences; D. Varshavi, M.R. Viant, University of Birmingham / School of Biosciences; S. Robson, University of Portsmouth / School of Pharmacy & Biomedical Science; I. Werner, Swiss Centre for Applied Ecotoxicology / Department of Anatomy Physiology and Cell Biology; A. Ford, University of Portsmouth / Biological Sciences

Chemicals coming from sewage effluents, can be detected in the aquatic environment in very low concentrations. Interest in exploiting “omics” approaches to screen the toxicity of chemicals in model species increased substantially in the last decade. Gammarids (*Gammarus fossarum*) have been shown as very sensitive to pollution. However, to date no reliable molecular markers are available in these species. The aim of this study is to investigate the changes in metabolome between amphipods sampled up- and downstream of an industrial wastewater treatment plant (WWTP). Differential metabolites can be used to further investigations of biological pathways affected by exposure to chemical mixtures coming from sewage effluents. *G. fossarum* were sampled from a Swiss freshwater stream in September 2017, using a standard kick-net method. Sampling was performed 50 m downstream and 50 m upstream of the WWTP. A total of 42 amphipods were sampled. A chloroform-methanol extraction protocol was performed on each amphipod and both polar and non-polar extracts were analysed using a LC-Orbitrap Elite platform. Each sample was analysed in both positive and negative ionization modes. Unsupervised multivariate models were built to calculate the rate of separation among the samples and univariate t-tests were performed to calculate the number of significant differential metabolites. Despite there were hints of separation between up- and downstream populations when looking at the PCA plots, for both male and female samples, t-tests showed no significant differential metabolites in female samples, neither in polar nor in non-polar extracts, in both positive and negative ionization modes ($p>0.05$). However, in the male polar extracts, t-tests revealed 28 and 69 differential metabolites, in negative and positive ionization modes, respectively. 44 differential metabolites between up- and downstream populations were detected in non-polar phase of the male samples, using a positive ionization mode. The source and identity of these metabolites is currently in progress. A further investigation of the differential metabolites found in the male samples could reveal impaired pathways in response to a chronic exposure to anthropogenic chemical mixtures in water. The metabolic fingerprints suggest different responses between female and male amphipods, supporting our transcriptomics data. These results suggest that males and females might be responding differently to waste water effluent.

MO103

Non-Target Analysis of the Organic Fraction of Fine Particulate Matter Using Gas Chromatography - High Resolution Mass Spectrometry

I. Sadiktsis, Stockholm University, ACES / Department of Environmental Science and Analytical Chemistry ACES and Science for Life Laboratory; L. D'Agostino, Stockholm University, ACES / Chemistry; K. Budhavant, A. Andersson, . Gustafsson, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES and Bolin Centre for Climate Research; J.W. Martin, University of Alberta / Department of Environmental Science and Analytical Chemistry ACES and Science for Life Laboratory

Exposure to air pollutants and particles is associated with increased morbidity and mortality from cardiopulmonary diseases and lung cancer, and is estimated to cause 7 million premature deaths annually worldwide. Fine particulate matter (particles with an aerodynamic diameter < 2.5 Âm; $PM_{2.5}$) is one component of air pollution that has been suggested to play an important role for adverse health effects. The chemical composition of fine particulate matter is highly complex and heterogeneous, and depends on its primary sources and atmospheric transformation processes. Research suggests that the organic components of fine particulate matter have adverse effects on human health and the environment. Some of the adsorbed organic compounds, such as PAHs and quinones, are suggested to play an important role in the toxicity of particles. Other organics in $PM_{2.5}$, such as nitro-phenols, may also affect global climate because of their light absorbing properties, while adsorbed persistent organic pollutants may be subjected to long-range transport. However, much of the organic composition of fine particulate matter is still unknown and not routinely monitored. This work presents a non-target workflow for comprehensive chemical characterization of semi-volatile organic compounds in $PM_{2.5}$ by gas chromatography (GC) coupled with an Orbitrap high resolution mass spectrometer. $PM_{2.5}$ was collected at the Climate Observatory at Hanimaadhoo (MCOH) in the Maldives between January and April 2019 on quartz fibre filters using a high volume air sampler. MCOH is a receptor location for the Indian and Bangladeshi source regions. Filters were extracted by a range of organic solvents followed by pre-concentration and silica gel column cleanup. The organic components were separated by GC and ionized under different ionization modes for comparison: electron ionization at 70eV (EI), positive chemical ionization (PCI), and negative chemical ionization (NCI). Data were analyzed in various ways, including by: (1) spectral matching to NIST database in EI-mode, (2) assignment of unequivocal molecular formula in PCI-mode, followed by database searches in ChemSpider and MS/MS structural elucidation, (3) flagging of potentially persistent, bioaccumulative and toxic organohalogen compounds in NCI mode.

MO104

Soft ionization mediated by inert gas for screening of halogenated compounds by GCxGC-HRToFMS

T. Ieda, National Institute for Environmental Studies; S. Hashimoto, National Institute for Environmental Studies / Center for Environmental Measurement and Analysis; K. Tanabe, National Institute for Environmental Studies

Recently, non-target screening by high resolution mass spectrometry (HRMS) coupled with gas or liquid chromatography (GC or LC, respectively) has been used to elucidate the myriad of environmental pollutants. The authors also have been developing a non-target screening method for environmental samples by using comprehensive two-dimensional GC (GC × GC) - high resolution time-of-flight mass spectrometry (HRToFMS) with electron ionization (EI). The EI method has several advantages, however, it is sometimes difficult to estimate molecular formula of unknown compounds when molecular ions are not detected. Therefore, we evaluated soft ionization mediated by inert gas aiming sensitive and selective detection of molecular ions for organohalogen compounds in environmental samples. GC × GC-HRToFMS analyses were performed with a Zoex KT2006 loop-type modulator (Zoex Corporation, Houston, TX, USA) installed on an Agilent 7890A gas chromatograph (Agilent Technologies, Palo Alto, CA, USA) with a JEOL AccuTOF GCv 4G (JEOL, Tokyo, Japan). Argon (Ar) or helium (He) was used as moderating gas for the soft ionization (negative ion mode) and compared to chemical ionization with methane (CH_4) in this study. A standard solution containing organohalogen compounds (ES-5521(CIL)) was measured at various parameters, such as reagent gas flow rate, ion source temperature and electron acceleration voltage. Optimum conditions were investigated based on mass spectra and intensities of molecular ions. As a result, the ion source temperature affected on sensitivity in soft ionization with inert gas (Ar or He), and lower temperature improved ionization rate of molecular ion especially for highly chlorinated compounds. As for PCB209, the highest intensity of molecular ion and less number of fragment ions were observed when Ar was used as moderation gas and ion source heater was off. After the optimization of parameters, a crude extract of house dust (NIST SRM 2585) was analyzed by GC × GC - EI/soft ionization - HRToFMS. The effectiveness of soft ionization mediated by inert gas for non-target screening will be discussed in the presentation. **<strong>Acknowledgments** The authors thank Mr. Yukinori Yahata of JEOL Ltd. for his support and technical comments. This work was supported by JSPS KAKENHI Grant Number JP17K12833, 17H00796.

MO105

Time trends of emerging contaminants in sediment cores from a wastewater impacted recipient identified by high resolution-mass spectrometry

G. Horlitz, Stockholm University, ACES / ACES; Z. Li, Stockholm University / ACES; A. Sobek, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES

Sewage treatment plants (STPs) are a major source of emerging organic contaminants of concern to receiving waters, as conventional (three-stage) wastewater-treatment processes are insufficient for many of these compounds. In addition, degradation-processes lead to transformation products that add to the total number of chemicals in the environment. There has been a number of studies focusing on the target and non-target analysis of emerging organic contaminants in surface waters, but the knowledge about their distribution and fate in sediment is still scarce. In this study, suspect and non-target screening was performed in sediment cores from a wastewater recipient in a study area impacted by urban- and agricultural-influences. A reference sediment sample was collected before the STP and sediment cores were taken both in a transport- and an accumulation bottom downstream. An efficient extraction method using salting-out-assisted liquid-liquid-extraction (QuEChERS) was optimized to extract a large range of compounds. Target and non-target analysis was performed by using UHPLC coupled to an Orbitrap mass spectrometer operated in full scan MS mode with data-dependent acquisition (top N) MS/MS mode. Identification of unknowns was done by matching obtained mass spectra with spectral library data (mzCloud). A large number of tentatively identified compounds originate from pharmaceuticals and personal care products and show concentration trends with increasing sediment depth that are in agreement with results from our prior target findings. A majority of the identified compounds show increasing concentrations towards surface sediment, which agrees with an increased usage in recent years.

MO106

Automated solid-phase extraction for seven neonicotinoids and fipronil in river- and seawater samples.

A. Wittmann, Helmholtz Centre Geesthacht / Environmental Chemistry; C.P. Bento, J. Gandraß, Helmholtz-Zentrum Geesthacht / Department for Environmental Chemistry; D. Kötke, Helmholtz-Zentrum Geesthacht / Department of Environmental Chemistry; R. Ebinghaus, Helmholtz-Zentrum Geesthacht / Department for Environmental Chemistry

With the recent ban of some neonicotinoid insecticides and the increasingly strict regulations on the use of systemic pesticides, the demand for quick, reliable and efficient analytical methods with low quantification limits is increasing. While manual solid-phase extraction (SPE) is currently the method of choice regarding sample preparation and enrichment for the determination of neonicotinoid insecticides in aqueous samples, the drawbacks are an extensive workload and a vulnerability for process variations. Here, SPE-automation can be an appropriate approach to reduce the manual workload and thereby free up laboratory resources, while at the same time increasing process parameter stability. The goal of the work here presented is: 1) the optimization and automation of the SPE process, using a LC-Tech FREESTYLE XANA device (LCTech GmbH, Obertaufkirchen, Germany), for the HPLC-MS/MS determination of 7 neonicotinoids and fipronil in varying environmentally relevant concentrations, and 2) the method validation and subsequent application to real field samples collected in the Bohai Sea and selected rivers of the Shandong province (China). In order to achieve this goal, a comparative literature research laid the foundation upon which a suitable approach for the SPE of neonicotinoids and fipronil was selected, modified and optimized for automated sample clean-up of brackish and sea water matrices. Results on the recoveries and performance of the automated SPE, using hydrophilic-lipophilic balanced sorbent cartridges and common solvents, are reported.

MO107

An Online Solid Phase Extraction-High Performance Liquid Chromatography-Tandem Mass Spectrometry Method for the Quantification of Neonicotinoid Pesticide Biomarkers in Human Urine

M. Ospina, Centers for Disease Control and Prevention (CDC) / Organic Analytical Toxicology Branch; S. Baker, A. Bishop Serafim, P. Morales Agudelo, M. Vidal, A. Calafat, Centers for Disease Control and Prevention

Neonicotinoid insecticides are currently a widely used replacement for the toxic organophosphates and carbamates. They are also used in lawn treatments and are effective for flea control in cats and dogs. However, the extent of human exposure to neonicotinoids is limited. We developed a high-throughput online-solid phase extraction-high performance liquid chromatography-isotope dilution tandem mass spectrometry (HPLC-MS/MS) method to quantify the urinary concentrations of four neonicotinoid pesticides: acetamiprid, clothianidin, imidacloprid, and thiacloprid; and two neonicotinoid metabolites: N-desmethyl-acetamiprid and 5-hydroxy-imidacloprid. The method uses 0.2 mL of human urine and uses an overnight enzymatic hydrolysis of glucuronide-conjugated species. The six analytes of interest are retained, washed and concentrated via online solid phase extraction (SPE), separated from each other and other urinary biomolecules using reversed phase high performance liquid chromatography (RP-HPLC), ionized by heated electrospray ionization (HESI) in positive ion mode and detected using tandem mass spectrometry (MS/MS). Accuracy ranged from 91 to 116 % and precision ranged from 3.7 to 10 %RSD. Limits of detection are all $< 0.5\ \mu g/L$, depending on the biomarker. The method has adequate accuracy, precision, and sensitivity to be applied to large–scale epidemiological studies, such as the National Health and Nutrition Examination Survey.

MO108

Analysis of antibiotics in food producing animals by LC-MS/MS

M. Shoeb, R. Islam, N. Nahar, University of Dhaka / Department of Chemistry

Antibiotics are used to treat bacterial infections of animals and human in the case of illness. Repeated use of same antibiotics, patients gets resistance to those bacteria. Drug resistant bacteria like MRSA, VERA are a worldwide problem to cure patients in case of infections. Many antibiotics are also fed to cattle and broiler chicken in the firms in Bangladesh like other parts of the world. People of Bangladesh feel that beef and broiler chicken meat are not safe for health due to residual antibiotics in the meat. To determine the residual level of tetracycline, oxytetracyclin and chlortetracycline, and six sulfa drugs namely, sulfadiazine, sulfadimethoxine, sulfamethazine, sulfamerazine, sulfathiazole and sulfamethoxypyridiazine in beef and broiler chicken meat samples by LC-MS/MS coupled with ESI and QQQ mass analyzer, Shimadzu protocol of method of antibiotics analysis was modified and validated in terms of lope time, mobilizing gas flow rate, heating and collision energy. The modified method was validated by recovery experiments of control samples, spiking at 2 different concentration levels (5 & 10 ng/g). The accuracy was evaluated in terms of percentage recoveries and precision was estimated by determining the co-efficient variances. Sensitivity of the LC was measured by evaluating LOD and LOQ at ng/g level. Identification of certified standard tetracycline was done by Q1 and Q3 Scan of precursor ion and 3 product ions, m1, m2 & m3. Quantitation was done using calibration of product ions by MRM (Multi-reaction Monitoring). Intra- (n=5) and inter (n=3) day recoveries were found to be in the range of 86-104%. Residual antibiotics were found to be below the detection limit.

MO109

Distribution of organic micropollutants in water and sediments from Lake Mälaren, Sweden

O. Golovko, Swedish University of Agricultural Sciences (SLU) / Department of Aquatic Sciences and Assessment; A. Rehrl, Swedish University of Agricultural Sciences (SLU); S.J. Köhler, Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; L. Ahrens, Swedish University of Agricultural Sciences SLU / Dept. of Aquatic Sciences and Assessment

The occurrence and distribution of organic micropollutants (OMPs) were evaluated in lake water and sediment of Lake Mälaren (Sweden) in autumn 2017. A liquid chromatography-tandem mass spectrometry method was applied to determine the OMPs concentrations in water and sediment. The partitioning of contaminants between lake compartments was estimated by means of solid water distribution coefficients (K_d). A total, 32 and 29 OMPs were detected in lake water and sediment, respectively, at concentrations from low ng/L up to 89 ng/L (lamotrigine) in lake water and from low ng/g dry weight (dw) up to 28 ng/g dw (citalopram) in sediments. Carbamazepine, lamotrigine, caffeine and tolyltriazole were the most dominant compounds in lake water since they were found in all lake water samples collected. Eighteen OMPs were quantified in both matrices, which enable the calculation of K_d values. The highest concentrations of most OMPs were found in Lake Ekoln water and sediments, which is close to Uppsala, the fourth largest city in Sweden. This location is affected by WWTP effluent water from an incoming river and show that densely populated areas are more prone to adverse impacts by OMPs due to an elevated usage and discharge of OMPs to surrounding water bodies. Keywords: pharmaceuticals, aquatic environment, target analysis, sediments

Ethanol-blended fossil fuels: is reduction of atmospheric pollution the only concern?

M. EZE, Georg-August-Universität Göttingen / Department of Genomic and Applied Microbiology; S. George, Macquarie University, Sydney / Department of Earth and Planetary Sciences

The Clean Air Act (42 U.S. Code § 7401) is one of the USA's most influential environmental laws. Under the Clean Air Act Amendments of 1990, oxygen-containing organic compounds such as methyl-tertiary-butyl ether (MTBE) or ethanol must be added to gasoline in some areas of the USA to reduce air pollution. Since then, the use of ethanol has increased, with many countries formulating various forms of ethanol-fuel mixtures. Blends of E10 or less are in use in more than 20 countries around the world. In the USA, ethanol represented 10% of the gasoline fuel supply in 2011. These initiatives are targeted at combating CO_2 and particulate emissions, as oxygenates leave behind less carbon footprints. Noble as it may appear, this innovation is not without attendant consequences. One major implication is the effect of co-solvency on the leaching potentials of petroleum hydrocarbons. Of these, BTEX (benzene, toluene, ethylbenzene, xylene) and PAHs (polycyclic aromatic hydrocarbons) are of greatest concern. This is due to their toxicity and persistence in the environment. For example, Snape et al. (2005) in a study of fuel spills in Antarctica showed that the relatively insoluble dimethylnaphthalenes were not degraded. Similarly, Wang et al. (1998) found increasing resistance to biodegradation with increasing alkylation in the naphthalene family. Compounding this problem is the fact that groundwater contamination by these compounds from above-ground and underground fuel spills has been of growing concern in recent years. This portends danger for humans owing to their carcinogenicity. In view of this, our research investigated the effect of ethanol addition on the leaching potentials of four groups of recalcitrant PAHs present in diesel fuel, namely, trimethylnaphthalenes, dimethylphenanthrenes, pyrene and methylpyrenes. Their movement (as components of diesel fuel) was followed in a lab-based study of 90 cm x ID 13 mm soil columns. In addition, the leachates from each column were examined using gas chromatography-mass spectrometry (GC-MS) to determine their molecular compositions. Our results reveal that ethanol addition enhances the leaching potentials of these otherwise hydrophobic contaminants; with 10% ethanol significantly eluting all PAHs studied. This highlight the need for energy scientists to carefully consider the environmental impacts of ethanol-blended innovations holistically. It is not enough to save the atmosphere and ruin the hydrosphere.

MO111
Challenges in complying with legislation; How far should one proceed to check whether the environmental quality standard is met?
M. Kotte, RWS / Rijkswaterstaat; O. Epema, Ministry of Infrastructure and Water Management / Rijkswaterstaat
Within the framework of various international river basin programs organotin pollution is monitored in Dutch surface waters. Tributyltin (CAS number: 36643-28-4) is one of many chemical parameters that determine the chemical status according to the Water Framework Directive (WFD). Environmental quality standards for tributyltin are defined in the Priority Substances Directive (DIRECTIVE 2013/39/EU). Dutch water authorities have put great effort into readily measuring tributyltin concentrations in their surface waters. The poster presented at SETAC Europe 2019 will go into the developed analytical method, the challenges faced to comply with the so-called QA / QC directive, and results of measurements of tributyltin in the Dutch waterbodies as part of the second round of river basin management plans. The main challenge was to comply with the desired reporting limit of one third of the year average EQS, being 0.2 ng/L. For the first round of river basin management plans tributyltin could not be analysed on that level. This led to an unknown chemical status for tributyltin. Rijkswaterstaat has used a sophisticated method using GC-ICP-MS instead of GC-MS to determine tributyltin in surface water. Headspace solid phase micro extraction is used to collect analyte from the sample. Gas chromatography combined with inductively coupled plasma and isotope dilution sector field mass spectrometry is used to separate, identify and reliably quantify the analyte. Due to extensive automation the ultimate method is not at all time consuming abut took a considerable stretch of time to develop. The desired reporting limit was achieved. The monitoring program has ultimately led to a better insight into the chemical status due to tributyltin. It is now clear which waterbodies meet the environmental quality standards and which do not. This is important because this way mitigating measures can now be taken to improve the aquatic environmental conditions. The question however is how far one should go to make sure the desired reporting limit is reached. It can (and will) be argued that one should perform a cost-benefit analysis taking into account not only costs of sampling and analyses, but also predicted (future) costs of mitigating measures.

Assessment of the French metals demand induced by national consumption and its associated environmental footprint
S. Muller, BRGM; F. Lai, BRGM / Waste and raw material unit; B. Boitier, SEURECO; J. Villeneuve, BRGM / Waste and raw material unit
Two main characteristics of the circular economy (CE), as defined in the French strategy of energy transition towards a CE, are a resource efficient economy and a low carbon economy. To assess strategies to be implemented towards a CE, both of these characteristics have to be simultaneously assessed to avoid burden shifting. The aim of this work is to show how environmentally extended multiregional input output approaches (EEMRIO) can be used to do so. EEMRIO databases were developed to take into account the environmental impacts of international trades; they consist in the coupling of two tables respectively describing the industries interdependencies in a given region along with the interregional interdependencies and the environmental interventions related to each industry. In this work, the EEMRIO databases WIOD and EXIOBASE v3 are used to determine both the metal and carbon footprints due to metal extraction and production (namely the “metal carbon”) induced by the French domestic consumption. Given their characteristics and their mathematical handling, the EEMRIO allow to access different types of results: the metal footprint and the metal carbon content of the products and services consumed domestically by France and the metal footprint and the metal carbon content of the economic activities induced by French domestic consumption. Following these indicators with WIOD, from 1995 to 2009, the total metal footprint of the French domestic consumption raised from 101 megatons to 143 megatons while the metal carbon footprint decreased from 38.6 megatons CO_{2eq} to 32.9 megatons CO_{2eq}. Moreover, most CO_2 due to metal processing is emitted in France (the similar assessment performed with EXIOBASE v3 shows that this is due to iron and steel industries) while metals are no longer extracted in the French territory. As it is a bit more disaggregated, EXIOBASE v3 allows a more specific assessment of the metal sectors and its impacts, for example construction related products that contributes the most both to the metal footprint and to the metal carbon content. EEMRIO permits the environmental assessment of the consumption flux in a national or regional level. Here the assessment was made on metals, but studies on material and carbon footprints can also be made on other products or services. One of the main drawback of EEMRIO, that has to be kept in mind when assessing consumption scenarios, is the age of the data available in publicly available databases.

MARILCA: A new working group on Marine Impacts in Life Cycle Assessment
A. Boulay, CIRAIG - École Polytechnique de Montréal / Chemical engineering department; J. Woods, NTNU The Norwegian University of Science and Technology; I. Vázquez-Rowe, Pontifical Catholic University of Peru / Civil Engineering Environmental Science; R. Geyer, University of California Santa Barbara / Bren School of Environmental Science and Management; F. Verones, NTNU / Department of Energy and Process Engineering
Impacts from marine litter, including plastic litter, are currently not included in life cycle impact assessment. This means that while plastic bans are rapidly taking place, there is no methodology to support whether the alternatives are better choices or not, since potential environmental impacts cannot be compared on the same basis. A working group was launched at the end of 2018 under the UN Environment Life Cycle Initiative, and with Forum for Sustainability through Life Cycle Innovation (FSLCI) as a communication and network partner. The objective of the working group is to foster the harmonized development of environmental impact pathways and characterization factors for marine impact assessment in life cycle assessment (LCA), in priority associated with marine litter. The current, primary focus is plastic. This project will allow, in the short-term, to coordinate and encourage the harmonious development of impact assessment methods, and, in the longer term, to integrate the marine impacts in LCA, including those from plastic litter, in a consistent approach that is compatible with the LCIA framework. Three main phases will characterize the project: Phase 1: Provide a first Framework paper developing and illustrating the different impact pathways associated with marine litter to be developed and identify the gaps and building blocks (November 2018 – June 2019). Phase 2: Coordinate and launch different research aiming at filling identified gaps and act as a central scientific reference on the topic to avoid overlaps (2019 - 2022), welcoming members who are working and contributing on the topic. Findings and updates are regularly discussed with stakeholders via a platform and workshops. Phase 3: Consensus building (2023-2025). Deliver a harmonized and consensus-based impact pathway framework and methods addressing plastic litter impacts (and potentially other complementary marine impacts) in LCA. Updates on and plans of the working group members, projects and deliverable will be provided in this communication, with the intention to raise awareness of the community and interest towards this important work.

Life cycle environmental impacts of a novel value-creating method to co-process coal mine and electronic wastes
V. Kouloumpis, X. Yan, University of Exeter / College of Engineering, Mathematics and Physical Sciences
The CEReS method is developed within a European research project aiming at value creation by co-processing coal mine and electronic waste. The processes developed involve using the acid mine drainage (AMD)-generating coal wastes in a way that a leaching solution (lixiviant) can be produced. This lixiviant can in turn be used to solubilise metals from printed circuit boards (PCBs) taken from electronic wastes (e-wastes). In this way, not only the environmental impacts from the two waste streams can be reduced but also valuable metals can be produced, which in turn can help avoid the mining for virgin materials. The aim of this paper is to present the life cycle environmental impacts of this novel method developed within the CEReS project. The functional unit is the processing of 1 tonne of PCBs and the system boundary includes their transportation, shredding and three core processes of the CEReS method: pyrolysis, bioleaching and char leaching. Data have been collected through mass flowsheets and a preliminary life cycle assessment (LCA) model has been created using the GaBi software and the GaBi professional and Ecoinvent databases. The preliminary model so far is not able to prove whether the CEReS method is beneficial because the data for the bioleaching and char leaching are not available yet and the exact amounts of the valuable materials that will be recovered remain unknown. When the model is finalised and the exact amounts of materials recovered are calculated, it is expected that the CEReS method will reduce environmental impacts compared to an alternative scenario where PCBs go to hazardous waste incineration. This will provide evidence that whether the CEReS method is environmentally beneficial as a Circular Economy approach to securing sustainable supply of critical raw materials.

MO116
Comparative environmental assessment of improved foam glass material using alternative waste glass streams (CRT and flat glass)
C. Rodrigues, ADAI/LAETA - University of Coimbra / Department of

Mechanical Engineering, Faculty of Sciences and Technology; J. König, Jozef Stefan Institute; F. Freire, ADAI/LAETA - University of Coimbra / ADAI-LAETA, Mechanical Engineering
Buildings' envelope plays an important role in the overall energy balance of buildings. Better thermal insulation is achieved with increased insulation thickness or with improved insulation performance. In order to meet the EU and global energy efficiency demanding requirements for net zero energy buildings, it is important to develop thermal insulation materials with even more superior thermal characteristics to reduce the wall thickness while increase its thermal resistance. The goal of this paper is to perform an environmental assessment of an improved foam glass using alternative waste glass streams as raw material as well as compare these materials with alternative thermal insulation materials available in the market (insulation cork board, EPS, XPS and stone wool). A cradle-to-gate life-cycle model was implemented for two options (CON13 and BG20) selected from a set of samples under experimental development to reflect a range of properties and thermal performance. CON13 uses CRT panel waste glass and BG20 uses waste flat glass.Two alternative functional units (FU) were assessed to increase the robustness of the analysis: 1 kg of material and 1 m^2 of insulation material providing 1 m^2K/W of thermal resistance (R). Presenting the results only per kg or cubic meter (as most LCA studies, including EPDs, present the results) may be limited and misleading as the primary function of an insulation material is to provide thermal resistance. The results for four environmental categories and non-renewable primary energy show that BG20 present lower environmental impacts (< 10%) than CON 13 when assuming 1 kg as FU while CON13 present lower environmental impacts when assuming 1 m^2K/W as FU. Both foam glass options present lower environmental impacts per kg than the alternative thermal insulation materials in three out of five categories analysed. For ozone layer depletion and non-renewable primary energy, stone wool present lower environmental impacts. It can be concluded that foam glass has a great potential for improvement in terms of environmental performance as present lower impacts than most of the conventional insulation materials. The use of a functional unit based on thermal properties proved to be a much more robust and holist unit when comparing insulation materials. Further research can be done on assessing the environmental benefits of including waste or recycled material on conventional insulation materials in a circular economy perspective.

MO117

Driving in circles: can car-sharing enable circular mobility? An investigation into the life-cycle impacts of car-sharing

D.A. Chapman, KU Leuven / Department of Materials Engineering; J. Eyckmans, KU Leuven / Faculty of Economics and Business; K. Van Acker, KU Leuven / Materials Engineering
Car transport is inefficient in terms of fuel-use and material-use compared to public transport. These efficiencies can be improved by technology, but the car is unlikely to ever supersede public transport. Car-sharing is one possible solution to enable a more circular transport sector by inducing changes to both user behaviour and cars' use-intensity. Most impact studies suggest that car-sharing users get rid of a car when they join car-sharing; these users also often increase public transport use at the expense of car-use. Moreover, car-sharing providers are expected to respond to economic incentives to increase the longevity, fuel efficiency and use-intensity of their car fleets, providing further reductions to both emissions and resource use. However, car-sharing is a completely new way to "consume" mobility, and the full effects are uncertain. What is needed is a rigorous impact evaluation of car-sharing to assess what the true causal impacts of car-sharing are. In this study, we have completed a life-cycle analysis of car-sharing, including both user and provider responses, to estimate the impacts on both resources and the environment. The method is rooted in a systems approach and rigorous impact evaluation. First, we identified the mechanisms that affect environmental benefits. Second, we collected data from both car-sharing users and non-users to understand how car-sharing users' behaviour changes. Third, we created the life cycle inventory with the users' behavioural changes and data from car-sharing providers. Finally, an uncertainty and sensitivity analysis was performed to understand the effects of uncertainty, since car-sharing impacts are dependent on naturally variable and uncertain parameters. Additionally, the complex interaction of different effects means that, under certain circumstances, car-sharing may not lead to lower resource use or environmental benefits. In sum, this study demonstrates the advantages of the integration of impact evaluation techniques and sensitivity analyses with LCA to give a more holistic view on the impacts of car-sharing. The results of this study will offer guidance to policymakers and researchers who aim to maximise the benefits of car-sharing and minimise any negative effects.

MO118

Assessing circularity by addressing recovery efficiency, contribution and recyclability

J.T. Quik, M. Zijp, RIVM / DMG; S. Waaijers-van der Loop, National Institute for Public Health and the Environment RIVM / Centre for Safety of Substances and Products; T. Traas, J. Lijzen, National Institute for Public Health and the Environment RIVM / Centre for Sustainability Environment and Health
There is a growing need for assessing circularity. This has several reasons, such as to monitor the circular economy in relation to the policy goals set, or to compare products in order to choose the best. Another reason is that there is a need to prioritize those activities that will help society transition towards a circular economy. Currently there are several methods that aim to assess or measure circularity. The most basic being the classification following the 9R strategies or more complex following a Life Cycle Analysis approach. Here we present a method aimed at assessing circularity of material recovery options. Where recovery options are seen as any process that uses residual material or a waste stream for the production of a secondary material. The indicators presented here address the fact that resource efficiency has several pillars which need to be included in a circularity assessment: 1) efficiency of the materials recovery process, 2) the contribution of the secondary materials to the materials-market demand for such materials and 3) future recyclability (second loop recycling). Each of these indicators is based on the relevant material flows and expressed as a score between 0 and 1. The approach was tested using two case studies. First on recovery of the phosphate mineral struvite from waste water for use in artificial fertilizer and second on the recycling of rubber from end of life tires (ELT) for use as infill material in synthetic turf pitches. Struvite recovery scored between 0.09 and 0.47 on recovery efficiency, the uncertainty lies in taking into account the additional materials needed in the recovery process or not. The ELT rubber scores 0.9 in recovery efficiency. The contribution to phosphate use, is 1% for phosphate from struvite. The contribution to infill use in the Netherlands was almost 90%. The recyclability of struvite is based on the losses in the use phase as accounted for in a mass balance and results in a score of 0.16. The recyclability of ELT rubber from synthetic turf pitches is scored as 0. This method to assess circularity should inform different stakeholders in the material recovery processes, i.e. regulators for giving permits or industry for prioritizing R&D. Other topics are also relevant to address when permitting or prioritizing recycling options. For this reason the Safe and Sustainable Loops framework includes other methods addressing the environmental impact and the risks from chemicals or pathogens.

MO119

How sustainable is the functional economy? Literature review about sustainability assessment methods applied to functional economy.

H. Moreau, Université Libre de Bruxelles / frInstitute for Environmental Management and Land Use Planning (IGEAT); V. Zeller, Université Libre de Bruxelles; W. Achten, Université Libre de Bruxelles / Geoscience, Environment and Society
As shown by the multitude of scientific articles as well as policy plans about the circular economy (Kirchherr et al., 2017), scientists and policy makers realize the need to go from a linear resource consuming economy to a more circular economy. The circular economy (CE) is an economic model where environmental pressure is decoupled from economic growth. This model can be implemented by companies in different ways of cycling resources and with alternative business models. Five or six different categories of alternative business models have been identified in literature, one of those being the Product Service System (PSS), including product-oriented, use-oriented and result-oriented services. The two last subcategories are part of the functional (service) economy which is the branch of CE which we will analyze in our work. The functional economy (FE) can be simply defined as the sale of a use of services instead of a material good. We can find many claims in the literature that the FE is more sustainable than traditional good ownership-oriented business models. The main argument is that FE could increase the units of service provided per unit of resource used, and could incentivize towards high resource cycling rates, which would result in higher resource efficiency and lower environmental impacts. However, the research community, aware of the importance to assess if FE truly increases sustainability, acknowledges a lack of empirical evidence of these claims and mechanism, e.g. in the form case studies evaluating positive or negative effects of the new CE business models. Our literature review focus on different variants of PSS, their mechanisms to affect resource cycling, and tools to assess their potential of sustainability. Our review considers peer-reviewed articles presenting case studies and reports from companies about PSS. For each of them we will analyze how the authors assess the different dimensions of sustainability (environmental, economic and social). Furthermore, the quantitative occurrence of tools will be evaluated to have a better understanding on how scientists evaluate sustainability. The first results show that even though LCA is considered as very time-consuming to do for businesses (Manninen et al., 2018) they are still used a lot to analyze environmental aspects. We also find that companies often develop their own tools (Moesch et al., 2018), especially to link environmental with economic aspects.

MO120

The environmental behavior of PEEK as an innovative material in a new portable hydrogen fuel cell

D. Garrain, CIEMAT / Energy Dpt Energy Systems Analysis Unit; S. Cabello, University of Castilla La Mancha; Y. Lechón, CIEMAT / Energy Dpt Energy Systems Analysis Unit
The E-Li-GE project (http://projects.ciemat.es/web/elige/home) funded by the Ministry of Science & Innovation of Spain, proposes a new way for portable energy generation, in the 1-100W power range. It is based on a hydrogen fuel cell (FC) with high power density. The key concept of the project is the integration of

the current collectors in the electrodes to decrease both weight and volume of the distribution plates and the end-plates, which largely contribute to reduce the FC power density. The new completely passive design also eliminates the weight and volume of unnecessary auxiliary systems and their associated power consumption, to make of this system a viable alternative for powering portable devices. In order to be compared to other alternative FC in terms of environmental aspects, the Environmental Footprint has been carried out. Polyether ether ketone (PEEK) is a thermoplastic with both excellent mechanical and chemical properties to high temperatures, which has been used as an innovative material due to its light weight and density. The objective of this work is to show the influence of the manufacturing of this material in the whole life-cycle of the FC.

MO121
Circular economy: Packaging recycling for energy savings and climate change mitigation
R. Dagiliute, Vytautas Magnus University / Environmental Science Department; J. Zaltauskaite, Vytautas Magnus University / Department of Enviromental Sciences; M. Janioniene, Vytautas Magnus University
Circular economy has emerged as a solution both for resources scarcity and dependency as well as for high environmental impacts related to the extraction of raw materials and waste management. High rate of consumption causes growing amounts of packaging waste - a specific waste stream, that gains a separate attention in EU waste policy. The most commonly used materials for packaging are paper, wood fibres, plastics, glass, steel and aluminium. Different packaging materials are associated with variety of environmental impacts during the whole life cycle of the packaging. Hence, recycling of those materials is one of the options for environmental pressure reduction. The aim of the study was to evaluate potential energy savings and greenhouse gas emission mitigation using recycled material instead of raw materials for beverage packaging. For this purpose, packaging use rate was evaluated in Lithuanian case. In the study, the primary energy consumption and GHG's indicator was estimated for 1 kg of packaging. Energy need and GHGs emission factors thru all life cycle of different packaging both from recycled and not recycled materials were selected from scientific literature review and applied for Lithuanian case. According to the packaging used, on the national level the largest primary energy consumption is for plastic packaging (~ 11 thousand GJ per year). If half of this type of packaging would be recycled around 3.000 GJ of energy could be saved. In the case of glass, the energy saving would reach 640 GJ, in the case of aluminium – even 4.000 GJ a year. In terms of GHG's in total about 37.000 tons of these emission could be saved with the aluminium packaging contributing the most into GHG's reduction. Hence, consumer awareness raising, and promotion of waste sorting behaviour still is important. In addition, the recycling of the packaging wastes could make a positive effect on the other environmental aspects, such as primary raw material and water use etc.

MO122
Is the single-use plastic ban by EU universally good? The case of airplane catering.
M. Delgado-Aguilar, Universitat de Girona / Laboratorio de Ingenieria Papelera y Materiales Poliméricos (LEPAMAP); G. Blanca-Alcubilla, ESCI, Universitat Pompeu Fabra / UNESCO Chair in Life Cycle and Climate Change; A. Bala, UNESCO Chair in Life Cycle and Climate Change (ESCI-UPF) / UNESCO Chair in Life Cycle and Climate Change; N. de Castro, Gate Gourmet; R. Puig, Universitat de Lleida / Computer Science and Industrial Engineering; P. Fullana, UNESCO Chair in Life Cycle and Climate Change (ESCI-UPF) / UNESCO Chair in Life Cycle and Climate Change
Abstract The European Parliament has recently voted for a complete ban on single-use plastic cutlery, together with: plates, straws, drink-stirrers, etc. With this, there is a clear aim to stop plastic (both micro- and macro-) pollution of the oceans, caused by land and coastal littering. There are different ecodesign strategies, some of them compatible, others mutually exclusive, depending on the system the strategy is being applied to. The most frequent are: dematerialization, weight or energy reduction, recyclability, re-usability, durability, degradability, bio-based, etc. For instance, weight reduction and degradability are often mutually excluded with durability or re-usability; recyclability may be good for some simple products and not so good for complex ones. The EU has decided that the best (and only?) strategy for improving the environmental impacts of single-use plastic cutlery is a material change. Currently, most airlines are using single-use plastic cutlery or multi-use steel cutlery for their catering services. The Zero Cabin Waste project is studying the environmental impact of plane catering waste management. The Ceres project is studying food production and consumption strategies for climate change mitigation. It is known that more than 90% of the impacts of air travel occur during the flight, due to the energy needed for operation. Our findings show that, because of this fact, the most effective ecodesign strategy for airplane catering cutlery is weight reduction, which is not compatible (by an order of magnitude) with the shift from single use plastic to steel cutlery to avoid littering. A better alternative would be to ensure that the plastic items are 100% controlled, collected and recycled, which would avoid littering as well as other impacts such as climate change, acidification, eutrophication, resource depletion, etc. This is difficult to develop in the majority of cases but not within a so controlled system such as aviation. Other ecodesign alternatives are also explored within these projects. **Acknowledgement** The authors are responsible for the choice and presentation of information contained in this paper as well as for the opinions expressed therein, which are not necessarily those of UNESCO and do not commit this Organization. Zero Cabin Waste (LIFE/ENV/ES209) is co-financed by the EU through the LIFE Programme. Ceres-Procon (CTM2016-76176-C2-1-R) is co-financed by the Spanish Ministry of Economy and Competitiveness.

Enhanced adsorption of phosphate from wastewater using chitin-calcium based waste material: From nutrient recovery to a new fertilizer product
S. Pap, Environmental Research Institute, North Highland College, University of the Highlands and Islands / Environmental Contamination and Ecological Health; C. Kirk, University of Edinburgh / School of Chemistry; S. Gibb, Environmental Research Institute, North Highland College, University of the Highlands and Islands, Castle Street, Thurso, Caithness, KW14 7JD, UK; B. Bremner, North Highland College, University of the Highlands and Islands / Environmental Research Institute; M. Turk Sekulić, University of Novi Sad Faculty of Technical Sciences / Department of Environmental Engineering and Occupational Safety and Health; M. Taggart, Environmental Research Institute / Environmental Contamination and Ecological Health
Phosphorous (P) is an essential macroelement, but too much phosphate in aquatic ecosystems can lead to a deterioration in water quality and eutrophication. P recovery from wastewater streams, through the adsorption of P onto natural, solid waste material may provide one solution. Ideally, this would be a low-cost solution that would create a P-rich material (low in other adsorbed contaminants) for direct use in agriculture as a fertilizer. Crab carapace, a waste by-product from the seafood industry, is generated in millions of tons annually and large quantities are simply discarded as waste (i.e., to landfill). Therefore, a feasible approach may be valorisation of this solid waste into a high value-added product. Chitin-calcium based sorbent from crab carapace was modified thermochemically with KOH to improve surface chemistry and pore structure. The raw material was milled and sieved to a particle size of < 100 μm, mixed with a KOH solution, then the impregnated material (CCM) was heated. Low temperature activation showed good results, with a P removal efficiency up to 80 %. The maximum monolayer adsorption capacities (q_{max}) exhibited the following order: 42 > 32 > 22 °C with 24.85 > 23.88 > 21.36 mg/g, respectively. Instrumental techniques, such as BET analysis, scanning electron microscopy/energy dispersive X-ray spectroscopy (SEM/EDX), Fourier transform infrared spectroscopy (FTIR), X-ray diffraction (XRD) and TGA/DTG analysis were used to determine the characteristics of the sorbent and future fertilizer material. The CCM had a high sorption capacity for phosphate, and low temperature activation was an innovative, sustainable and low-cost way to prepare a crab carapace-based sorbent for P recycling from wastewater. This research seeks to repurpose waste (crab carapace), close the P cycle and capture a globally limited resource (close the gap between P recovery and recycling), whilst also producing a new fertilizer product. Life cycle assessment (LCA) will be undertaken to help determine how best to create an efficient network of P capture (treatment) and re-use (as fertilizer) sites in rural locations. The sorbent will be tested in a FiltraPHOS™ pilot-scale P removal unit for use on small rural wastewater discharges. FiltraPHOS™ employs enhanced gravitational filtration through a granular media with continuous self-backwashing.

MO124
How critical raw materials could influence LCA impact categories in renewable energy systems
D. Garrain, Y. Lechón, CIEMAT / Energy Dpt Energy Systems Analysis Unit
Critical Raw Materials (CRM) awareness have arisen as both research and policy issues due to the future importance not only in economic but also in social and environmental world development. These concepts are related to those raw materials which are economically and strategically important for the world economy, have a high-risk associated with their supply, and there is a lack of viable substitutes. Energy systems, like PV solar modules or wind turbines, have metals or rare earths that are potentially included in these CRM. This work aims to identify the potential CRM in these technologies and quantify the potential influence on LCA impact categories, such as toxicity or abiotic resource depletion, when end-of-life actions to improve the sustainability and the circular economy, such as substitution or recycling of those materials, are carried out.

MO125
Life cycle assessment of hot-dip galvanizing process
A.A. Maza, M. Margallo, University of Cantabria / Chemical and Biomolecular Engineering Department; A. URTIAGA, University of Cantabria VAT Nº QC / Chemical and Biomolecular Engineering
Hot dip galvanizing (HDG) is a surface treatment used to prevent steel corrosion. Zinc coating increases lifespan of steel in an economical way compared to industrial paintings. Although few studies have assessed the environmental impact of the whole production of galvanizing steel pieces, including steel production, none of them have analyzed the stages of HDG in detail. The aim of this work is

to conduct a life cycle assessment (LCA) of HDG based on data from this industry in Spain, within the framework of the EU project LIFE-2-ACID: *Towards a sustainable use of metal resources in the galvanic industry* (LIFE16 ENV/ES/000242). The cradle to gate study includes the extraction of raw materials, alkaline and acid degrease, acid pickling, flux, drying and hot dipping galvanizing, as well as waste and wastewater treatment. The life cycle inventory (LCI) referred to one ton of galvanizing steel was collected from Spanish companies by means of visits and questionnaires ensuring the quality and representativeness of the LCI, and for secondary data, Ecoinvent and PE International database were used. The system was modelled using Gabi software and CML 2001 including the categories of global warming potential (GWP) [kg CO_2 eq.], ozone depletion potential (ODP) [kg CFC-11 eq.], photochemical ozone formation (POF) [kg C_2H_4 eq.], acidification potential (AP) [kg SO_2 eq.], eutrophication potential (EP) [kg PO_4^{3-} eq.], abiotic resources depletion (ADP) [kg Sb eq] and abiotic-fossil resources depletion (ADP-fossil) [MJ]. The results showed that drying and hot dipping galvanizing stages have the highest contribution in most of categories, representing c.a. 90% of the impact in GWP, POF, AP, EP, ADP, and ADP-fossil because of the demand of zinc and the consumption of natural gas. In addition, the transport of raw materials had a significant impact in the GWP, EP, AP due to the emission of greenhouse gases and acid substances. Based on these results, LIFE-2-ACID project proposes a technological alternative to recover metallic zinc and iron chloride from spent pickling acids, which is the main waste generated in the HDG process. The innovative technological solution integrates membrane based selective extraction and electrowinning to recover up to 10% of zinc that is lost in the acid pickling. Thus, LIFE-2-ACID develops the emerging concept of circular economy using a hazardous residue as raw material available to reuse it in the same or other processes.

MO126

LCA on circular asphalt production in Denmark

H. Larsen, Danish Technological Institute / Research and Development

The technical possibilities and relative sustainability of using reclaimed asphalt in new wearing courses have been investigated in a recent Danish research project. The project focused on optimization of the individual steps of the process chain, starting from the milling of the old, worn asphalt pavement, to the production of the new hot asphalt containing recycled asphalt from worn out wearing courses. The necessity to mill off wearing courses and base courses separately, has been established. Following a comprehensive laboratory test program, full-scale validation of the concept was carried out on a part of a new highway in central Jutland of Denmark. All the obtained results unanimously show that – within the given frames – addition of 30% reclaimed asphalt wearing course into the production of new SMA wearing courses, as well as ABB binder courses, results in the same functional properties and expected durability as for 'virgin' produced reference asphalt material of the same type. In order to investigate the relative sustainability a comparative LCA study was performed comparing the new wearing and binder courses with conventional types. Results show overall better environmental performance of the new types with reclaimed asphalt, e.g. 14-22% lower carbon footprint. Including two different LCIA methods and combining with several sensitivity analyses confirmed the overall result.

MO127

Life cycle assessment of woody biomass ash in construction materials as a way towards a circular economy

T. da Costa, University of Aveiro/Federal University of Pampa / Department of Environment and Planning; P. Quinteiro, L.A. Tarelho, University of Aveiro / Centre for Environmental and Marine Studies (CESAM) & Department of Environment and Planning; L. Arroja, University of Aveiro / Department of Environment and Planning; A.C. Dias, University of Aveiro / Centre for Environmental and Marine Studies (CESAM) - Department of Environment and Planning

The forest biomass utilization as a way of mitigating climate change in the energy production sector is an excellent way but needs to be sustainable to ensure the environmental benefits. A fundamental issue that should be investigated when using forest biomass to produce energy relates to the ash management. The valorisation of woody biomass ash in construction materials appears to be a good management alternative. The purpose of this work is to compare the environmental impacts of different woody biomass ash valorisation alternatives using a life cycle assessment. The ashes under study include both fly and bottom ash generated from the combustion of eucalypt and maritime pine residues in a fluidised bed. The functional unit used in this study is the disposal/valorisation of 1t of woody biomass ashes. Four different management alternatives were assessed: cement mortar, concrete blocks, bituminous asphalt and disposal in landfill. The system boundaries include the transport of the woody biomass ash from the power plant to its destination, the on-site processes and the production of materials/energy consumed in each scenario. Furthermore, when the ash is valorised, the product system is credited with an avoided burden based on the reduced requirement for virgin material production (cement, sand, gravel and limestone). It was observed that the impacts of fly ash valorisation in cement mortar and concrete blocks presented differences of less than 2 %, indicating that the production of cement mortar and concrete blocks with fly ash have similar benefits, since it avoids the production of cement. For bottom ashes, the results show a negative net impact for all valorisation scenarios except for the production of concrete blocks, since the bottom ashes substitutes the gravel and its contribution is small and the substitution by ashes does not minimize the effects of this impact. It should be noted that the net benefits of bottom ash valorisation tend to be smaller than those obtained for fly ashes, as substitution is only possible for the aggregates and limestone. The bituminous asphalt production with bottom ashes substituting limestone presented the largest benefit for all impact categories, followed by the production of cement mortar production substituting sand. It was also observed that the valorisation scenarios have a better environmental performance than ash landfilling, resulting in a significant decrease of the environmental impacts in some scenarios.

MO128

Should electrical and electronic equipment be repaired for a second life? Environmental profile of electronic appliances: repair vs. substitution schemes

P. Villanueva-Rey, EnergyLab / Industry and Sustainable buildings; D. Quiñoy, P. Martínez, D. Mariño, G. Rodríguez, EnergyLab

Waste of electrical and electronic equipment (WEEE) is one of the fastest growing waste streams in Europe, expecting to grow up to more than 12 million tones by 2020. Given their complex mixture of materials and components —in some cases hazardous substances—, WEEE can cause environmental and health problems when they are not managed correctly. In addition to this, the production of modern electrical and electronic equipment (EEE) requires the use of scarce and expensive resources —i.e. critic raw materials— that sometimes are landfilled and not recovered. The released of the Directive 2012/19/EU established the base for WEEE stream management within EU countries, aiming at reducing environmental and health impact impacts, as well as increasing material recovery. Likewise, following the EU's Waste Framework Directive, polluter pays, extended producer responsibility and the waste management hierarchy principles were also incorporated into WEEE directive. As a result, the whole supply chain —from manufacturing to final disposal— of EEE must be addressed to comply with regulations and requirements. Achieving the established goals in terms of preparing for re-use and recycling implies different actions: increase separate collection, adapt or build a net of clean points in order to separate components and classify WEEEs, create a market for secondary raw materials and repaired appliances, among other. In this context, the preparation for re-use and recycling of EEE must be evaluated from a holistic approach. Life cycle assessment (LCA) allows analyzing the environmental burdens related to waste management and treatment taking into account the whole supply chain of electronic appliances. Hence, the current study evaluates recycling and re-using schemes of two EEE categories (i.e. Large Household Appliances (LHA) and IT equipment and telecommunications) throughout LCA. The results obtained shows that environmental performance highly depends on EEEs electricity. In this sense, despite the fact that EEEs life span is enlarged for a second life —avoiding the impacts derived from manufacturing and distribution stages— by means of repair or refurbishment, it might increase its electricity consumption when comparing to new appliances, which usually have a higher energy efficiency. Therefore, for some cases, the acquisition of a new appliance presents better environmental performance than a repaired/refurbished one.

Latest Developments and Future Needs for Higher-Tier Studies, Risk Assessment and Risk Management in the Regulation of Biocides, Pesticides and Pharmaceuticals (P)

MO129

Regulatory ERA of Veterinary Medicines may be improved: I - Need for other and better exposure scenarios for surface water

I. de la Casa Resino, Spanish Medicines Agency / Veterinare Medicines; C. Moermond, RIVM / Centre for Safety of Substances and Products; A. Haro Castuera, C. Rubio Montejano, G. Cortés Ruíz, Spanish Medicines Agency / Department of Veterinary Medicines; R. Carapeto-García, Spanish Medicines Agency / Veterinary medicines

The main source of emission of many Veterinary Medicinal Products (VMPs) into the environment is the use of manure as fertilizer. In the current Environmental Risk Assessment (ERA) of VMPs, $PEC_{SURFACE\ WATER}$ is calculated running the FOCUS model, using a winter cereal scenario. However, the input data recommended by the relevant VMP ERA guidelines are not fully detailed. This leads to inconsistencies in the predictions. We propose an improved parametrization of FOCUS model for winter cereals. Although it is acknowledged in the ERA guideline that manure is often spread on grassland, this option is not considered for the determination of $PEC_{SURFACE\ WATER}$. The lack of a grassland scenario may affect the accuracy of predictions. Thus, it may be necessary to implement this scenario. The winter cereal scenario does not necessarily pose a worst case situation, that also covers a grassland application. In a crop scenario the VMP will be mixed in soil during ploughing while in grassland this dilution is negligible. Consequently, direct runoff is likely to be quantitatively more important in grasslands. Besides, for the winter cereal scenario it is assumed that manure will be spread once a year, while in grasslands it can be spread several times per year (both with a maximum kg N per acre per year). Thus, by including the grassland scenario in the current ERA of VMPs the conclusions would be more robust. There are some limitations for the implementation of the grassland scenario: 1) **Grassland scenario is not defined in FOCUS:** We reflect on this issue in another poster. 2) **Diversity of European agriculture:** Grasslands are dominantly present over the crops in certain countries while in other countries grasslands may be irrelevant. The differences could be so wide that it would be worthwhile to consider a zonal-RA. Regarding the winter cereal modelling, in the VMP ERA guideline a number of default input parameters regarding the FOCUS PRZM model is lacking. For instance, there is no recommendation regarding the Chemical Application Method and depth. Depending on the input parameters the results of the model can vary substantially. We propose the use of homogenous mixture of VMP during ploughing ('CAM 4') and a depth of 20 cm for the runoff scenarios (20 cm is an assumed ploughing depth in arable crops).

MO130

Regulatory ERA of Veterinary Medicines may be improved: II - a grassland scenario proposal

I. de la Casa Resino, Spanish Medicines Agency / Veterinare Medicines; C. Moermond, RIVM / Centre for Safety of Substances and Products; A. Haro Castuera, C. Rubio Montejano, G. Cortés Ruíz, Spanish Medicines Agency / Department of Veterinary Medicines; R. Carapeto-García, Spanish Medicines Agency / Veterinary medicines

The main source of emission of many Veterinary Medicinal Products (VMPs) into the environment is the use of manure as fertilizer. The current Environmental Risk Assessment (ERA) uses a modelling approach (FOCUS) to estimate the predicted surface water concentration ($PEC_{SURFACE\ WATER}$). In this model it is assumed that application of manures coincides with drilling of winter cereals. A grassland scenario is not available (See Poster I), although it is assumed to be more relevant to VMP applications to soil. Although in some countries manure is mainly spread on and mixed into arable land used for crop production, in other countries it is common practice to distribute manure directly onto grassland. Therefore, we aim to make a first proposal for the parameters and crop grouping that could be taken into account to develop a realistic grassland scenario for use in FOCUS models. Besides the currently used scenario for *winter cereals*, a *grass/alfalfa* crop is also defined in FOCUS. This scenario could be used as a pragmatic surrogate for grassland. The periods of manure application in grassland are usually between the 1st of February to the 1st of September. These applications dates are out of the application dates stablished in FOCUS for *winter cereals* (25th September to 15th of July) and therefore, do not cover all possible grassland applications in a realistic way. The applications dates considered for the grass/alfalfa crop cover the whole year and therefore manure application dates (1st February to 1st September) could be adjusted in a more realistic way. Furthermore, 3-4 applications per year may be applied in grassland. The mixing depth with the soil depends on the manure application system. Typical method is the surface application of manure in grassland through broadcast spreaders. In this case a mixing depth of 5 cm can be applied. Please note that the feasibility of the grassland scenario to be used in the marketing authorization process should be intensively discussed in a regulatory context before being used.

MO131

Development of a test method for transformation of veterinary pharmaceuticals and biocides in liquid manure

T. Junker, ECT Oekotoxikologie GmbH; S. Berkner, German Environment Agency / Section IV 2.2 Pharmaceuticals, Washing and Cleansing Agents and Nanomaterials; R. Duering, Justus Liebig University Giessen / Institute of Soil Science and Soil Conservation; S. Fiebig, Noack Laboratorien GmbH; D. Völkel, Innovative Environmental Services IES Ltd / Environmental Fate; J. Roembke, ECT Oekotoxikologie GmbH

Spreading of manure on agricultural soils represents an important path by which veterinary pharmaceuticals and biocides enter the environment. To assess their environmental impact in the context of authorization processes, experimental testing of transformation of these compounds in manure is considered in regulatory guidance documents. However, there is no standardized experimental test method available so far. To fill this gap, a reliable experimental test method was developed to examine transformation of veterinary pharmaceuticals and biocides in liquid cattle and pig manure. The development was a step-by-step procedure. In the first project, preliminary studies were performed with regard to manure characterization, sampling and storage. Manure parameters to comprehensively describe and characterize the respective manure were identified and their variability due to differences in storage conditions and in manure origin was analyzed. A standardized procedure was established to homogenize manure both in the manure storage tank and in the laboratory prior to performing transformation studies. In addition, the influence of manure storage conditions (duration and temperature) and manure acclimation periods in the laboratory on the microbial activity of manure was tested. Subsequently, two anaerobic intra-laboratory test series with ^{14}C-labelled compounds were performed to examine the influence of test set-up (flow-through vs. semi-static, flow rate, amount of manure) on mineralization rates and the influence of type and origin of manure on transformation rates (UBA Texte 78/2015, UBA Texte 78/2016). In a follow-up project the reproducibility of the test method was proven in an international validation ring test (UBA Texte 80/2016). The results and experience gained in both projects, as well as scientific discussions at two technical workshops and several international meetings, where then put together in a draft test guideline on anaerobic transformation in liquid manure. This draft contains a technical description of sampling, manure characterization, test design and chemical analysis, as well as recommendations to identify transformation products and the definition of quality criteria. The draft test protocol is planned to be submitted for evaluation and approval as standard test method by the OECD.

Veterinary pharmaceuticals and natural hormones in the environment after field applications of slurry

J. Lahr, Wageningen Environmental Research / Team Animal Ecology; A. Derksen, AD eco advies; L. Wipfler, Wageningen Environmental Research / Environmental Risk Assessment Team; M. van de Schans, B. Berendsen, M. Blokland, RIKILT; W. Dimmers, P. Bolhuis, R. Smidt, Wageningen Environmental Research

The Netherlands are a country of intensive livestock rearing. It is well known that the livestock sector uses significant quantities of veterinary pharmaceuticals (VMP's) such as antimicrobials, parasiticides, coccidiostats and various other groups of substances. In addition livestock is emitting natural hormones. In order to study the environmental fate of these groups of compounds, a field survey was conducted in the province of Gelderland in The Netherlands. Five pig rearing and five veal calve rearing farms situated on sandy soils were selected. In the early spring of 2017, the slurry collected over the winter season at these facilities was injected into arable fields and grasslands. This is common practice in The Netherlands in order to prevent ammonia emissions into the air. During four months after injection, the concentrations of VMP's and hormones were monitored in soil, in the shallow ground water under the fields and in the surface water and sediment of adjacent ditches. Most VMP's of which the farmers reported their use were detected in the slurry from the pits before land application. These included various tetracyclines, sulfonamides, macrolides and quinolones. The slurries also contained a large number of estrogens, androgens, progestagens and their metabolites. Several more hydrophobic substances were found to persist to various degrees in soil after application: the antimicrobials oxytetracyclin, flumequin and tilmicosin (the latter two are typical of veal calve rearing and possibly persisting for over a year in soil), the parasiticide flubendazole, the coccidiostat toltrazuril(-sulfon) and the androgenic hormones androstendione and β-testosterone. As expected, soluble VMP's tended to be found more often in ground and/or surface water: the antimicrobials sulfadimidin (synonym of sulfamethazin), sulfadiazin and tiamulin (but few hormones). In five regional streams in the same region, sampled once in July of the same year, some of the more soluble VMP's and hormones were also detected. The pregnancy hormone progesterone was omnipresent at low concentrations in all environmental matrices but not in any slurry samples. Its source is therefore unknown. The presence of the mentioned compounds in the environment as a consequence of slurry application warrants a more in depth assessment of the risks for soil life, aquatic organisms and the consequences for the production of safe drinking water from ground water.

Environmental risk assessment of veterinary pharmaceuticals - lessons learned from terrestrial effect data

S. Schwarz, German Environment Agency UBA; J. Bachmann, German Environment Agency UBA / Section IV2.2 Environmental Risk Assessment of Pharmaceuticals; J. Brueckner, W. Koch, Umweltbundesamt / German Environment Agency / Section IV Environmental Risk Assessment of Pharmaceuticals; G. Speichert, German Environment Agency UBA

Since the guidelines on the environmental impact assessment for veterinary medicinal products (CVMP/VICH/592/1998 & 790/2003) came into force, the German Environment Agency (UBA) is tasked with the environmental risk assessment of veterinary pharmaceuticals. Applicants seeking approval of medicinal products follow the Phase I guideline, which, if necessary, includes calculating predicted environmental concentrations (PEC). In case the PEC exceeds 100 μg/kg in soil, or if the substance is a parasiticide used on pasture animals, fate and effect data have to be provided in the more detailed Phase II assesment. Terrestrial effect studies include the investigation of plant growth (OECD 208) and earthworm reproduction (OECD 222). Furthermore, effects on development of dung flies and beetles (OECD 228 and OECD GD 122) are considered in the case of parasiticides used on pasture animals. Both the applicant and the assessor evaluate the studies to assure adequate data quality. The effect data are used to derive predicted no effect concentrations (PNEC) for the respective substance. Over the last decade, this regulatory work resulted in a comprehensive data base containing effect data on active pharmaceutical ingredients (APIs) – which was evaluated in our current project: The vast majority of APIs used in veterinary medicinal products belong to the groups of antibiotics and antiparasitics, which include a variety of highly potent substances. Approximately 40% of PNECs derived for soil organisms are below 100 μg/kg, illustrating that the current PEC action limit is not protective enough for the soil compartment. Furthermore, dung organisms frequently prove to be highly susceptible to antiparasitics used on pasture animals, which necessitates adequate risk mitigation measures for these substances. Our results will help to identify possibilities and limitations of the current regulatory approach, and provide information for future modifications of the regulatory framework.

MO134

Revison of the guideline on environmental risk assessment of human pharmaceutical products. Part I: Outline, data collection and tailored strategies.

C. Moermond, RIVM / Centre for Safety of Substances and Products; S. Brendler-Schwaab, Federal Institute for Drugs and Medical Devices; E. Griffin, Health Products Regulatory Authority; J. Jensen, Aarhus University / Department of Bioscience; B. Scholz, Swedish Medical Products Agency; L.S. Nilssen, The Norwegian Medicines Agency; H. Stemplewski, Medicines and Healthcare products Regulatory Agency; R. Whomsley, European Medicines Agency; I. Rönnefahrt, German Environment Agency - UBA / Section IV 2.2 Pharmaceuticals

According to Art. 8(3) of the European Directive 2001/83/EC an environmental risk assessment (ERA) is required for all new marketing authorisation applications for a medicinal product. This ERA is based on the use of the product and the physico-chemical, ecotoxicological, and fate properties of its active substance. A draft of the revised ERA guideline has been published for consultation by the European Medicines Agency in December 2018. This guideline describes how to perform this ERA and how to evaluate potential risks to the environment arising from the use of the medicinal product, with the aim of protecting aquatic and terrestrial ecosystems including surface water, groundwater, sediment, soil and secondary poisoning - and the microbial community in sewage treatment plants. Furthermore, the identification of potential hazards (PBT; Persistence, Bioaccumulation and Toxicity) of the active substance is described. In a series of 3 posters we will present this revised guideline, with a focus on the main changes. \n Poster I focuses on the general outline of the risk assessment. Information requirements, data quality, and the way data is collected and evaluated will bediscussed. Information is given on the tailored assessment strategies for antimicrobial substances and endocrine active substances and on the use of the total residue approach. In this poster, also the PBT assessment will be discussed. \n

MO135

Revison of the guideline on environmental risk assessment of human pharmaceutical products. Part II: Phase I risk assessment and PBT assessment.

C. Moermond, RIVM / Centre for Safety of Substances and Products; S. Brendler-Schwaab, Federal Institute for Drugs and Medical Devices; E. Griffin, Health Products Regulatory Authority; J. Jensen, Aarhus University / Department of Bioscience; B. Scholz, Swedish Medical Products Agency; L.S. Nilssen, The Norwegian Medicines Agency; H. Stemplewski, Medicines and Healthcare products Regulatory Agency; R. Whomsley, European Medicines Agency; I. Rönnefahrt, German Environment Agency - UBA / Section IV 2.2 Pharmaceuticals

According to Art. 8(3) of the European Directive 2001/83/EC an environmental risk assessment (ERA) is required for all new marketing authorisation applications for a medicinal product. This ERA is based on the use of the product and the physico-chemical, ecotoxicological, and fate properties of its active substance. A draft of the revised ERA guideline has been published for consultation by the European Medicines Agency in December 2018. This guideline describes how to perform this ERA and how to evaluate potential risks to the environment arising from the use of the medicinal product, with the aim of protecting aquatic and terrestrial ecosystems including surface water, groundwater, sediment, soil and secondary poisoning - and the microbial community in sewage treatment plants. Furthermore, the identification of potential hazards (PBT; Persistence, Bioaccumulation and Toxicity) of the active substance is described. In a series of 3 posters we will present this revised guideline, with a focus on the main changes. Poster II shows phase I of the risk assessment. This phase I consists of a decision tree, in which for each medicinal product a decision is made whether or not a phase II risk assessment is required. Specific attention is paid to generic HMPs, products containing naturally occurring substances and products with non-natural peptides/proteins as active substances. The decision tree ends with the calculation of a Predicted Environmental Concentration (PEC). If the PEC action limit is exceeded an ERA based on experimental studies is required in Phase II for at least surface water, sediment and sewage treatment plant. There are substances like endocrine active substances for which the PEC action limit does not apply and for which a Phase II assessment is always required. Depending on certain trigger values, it is determined whether additionally, a risk assessment for soil, groundwater or secondary poisoning should be performed. \n

MO136

Revison of the guideline on environmental risk assessment of human pharmaceutical products. Part III: Phase II risk assessment.

I. Rönnefahrt, German Environment Agency - UBA / Section IV 2.2 Pharmaceuticals; S. Brendler-Schwaab, Federal Institute for Drugs and Medical Devices; E. Griffin, Health Products Regulatory Authority; J. Jensen, Aarhus University / Department of Bioscience; B. Scholz, Swedish Medical Products Agency; L.S. Nilssen, The Norwegian Medicines Agency; H. Stemplewski, Medicines and Healthcare products Regulatory Agency; R. Whomsley, European Medicines Agency; C. Moermond, RIVM / Centre for Safety of Substances and Products

According to Art. 8(3) of the European Directive 2001/83/EC an environmental risk assessment (ERA) is required for all new marketing authorisation applications for a medicinal product. This ERA is based on the use of the product and the physico-chemical, ecotoxicological, and fate properties of its active substance. A draft of the revised ERA guideline has been published for consultation by the European Medicines Agency in December 2018. This guideline describes how to perform this ERA and how to evaluate potential risks to the environment arising from the use of the medicinal product, with the aim of protecting aquatic and terrestrial ecosystems including surface water, groundwater, sediment, soil and secondary poisoning - and the microbial community in sewage treatment plants. Furthermore, the identification of potential hazards (PBT; Persistence, Bioaccumulation and Toxicity) of the active substance is described. In a series of 3 posters we will present this revised guideline, with a focus on the main changes. \n Poster III shows the phase II risk assessment, for which it is mandatory to perform fate and ecotoxicity studies. Test requirements for the risk assessment of surface water, sediment, and sewage treatment plants are discussed. Depending on trigger values (see poster II), also a risk assessment for soil, groundwater and/or secondary poisoning needs to be performed. In this poster the way the risk assessment is performed for all these compartments is presented. Particular attention is given to the changes in the risk assessment strategy of the revised guideline compared to the ERA guideline currently in force (EMA/CHMP/SWP/4447/00 corr 2). \n

Recommendations for a future risk assessment tool for antimicrobial resistances in the environment. A regulatory approach.

M. Haro, I. De la Casa Resino, Spanish Agency of Medicines and Medical Devices / Veterinary medicines; G. Cortés Ruíz, Spanish Medicines Agency / Department of Veterinary Medicines; C. Rubio Montejano, Spanish Agency of Medicines and Medical Devices / Department of Veterinary Medicines; R. Carapeto García, Spanish Agency of Medicines and Medical Devices / Veterinary medicines

Therapeutic failure due to antibiotic Antimicrobial Resistance (AMR) is expected to cause more deaths than cancer by 2050. Action has been taken tackling the problem from a multidisciplinary approach following a "One health" philosophy. Environment plays a key role in the appearance and spread of AMR because it is a link between microorganisms in animals and people and it is a scenario for transmissible transmission of genetic variability and eventually receives antimicrobials as emissions from different sources (excreta, natural producer biota, etc.). Monitoring data on resistances in the environment, as already occurs for human and animal health, could be extremely useful for linking resistances to emissions and provide data to explore other factors that might affect to the appearance and spread of resistances. If risk assessors could reasonably predict risk for a resistance to arise and ultimately cause therapeutic failure, this would be a very much appreciated weapon to contribute to antibiotic prudent use. Assessors need that this could serve as a harmonized systematic decision tool. As it has happened in other frameworks, a "learn by doing" motto should be applied here, since prompt action is needed. The system should stablish a decision tree for the regulators to find systematic recommendations in order to refine risk. The workflow would proceed through a tiered strategy, with a simple, risk discarding approach as starters and proceed to a more refined analysis where experienced guidance by Academy or researchers should be sought by assessors. A battery of feasible risk mitigation measures need to be available. Prescribers and consumers should be well informed of the mitigation options and how to proceed for the measures to become a reality. The approach might need to consider a "think global, act local" horizon.

MO138

Can eprinomectin, a veterinary drug, induce chromosomal and nuclear damage at environmental concentrations?

R. Souza, C.P. de Souza, Sao Paulo State University - UNESP / Biology; S.S. Silveira, São Paulo State University UNESP / Biology; C.S. Fontanetti, Sao Paulo State University - UNESP / Biology; J. Guimarães, UNICAMP University of Campinas

In order to maintain the high productivity of the livestock sector and reduce financial losses caused by different diseases, large quantities of veterinary drugs are used by rural producers. Eprinomectin is one of the most commercialized drugs for this purpose and it is found in soil in concentrations ranging from ng/g to µg/g. It belongs to the avermectin family, commonly used to combat a wide variety of parasites, and approximately 90% of the drug can be excreted in the dung of treated animals, contaminating the soil. So the objective of this study was analyzing the ability of environmental concentrations of eprinomectin to cause damage in the genetic material of *Allium cepa*, widely used as a plant bioindicator. Fifity seeds of *A. cepa* were exposed in Petri dishes containing soil contaminated with eprinomectin in different concentrations: 0.5 µg/g, 2.5 µg/g, 12.5 µg/g and 62.5 µg/g. Negative control was performed with soil+distilled water and positive control with soil+herbicide trifluralin. As the stock solution to contaminate the soil with eprinomectin was prepared with ethanol, a control containing soil+ethanol was also performed. Tests were conducted in triplicate in a BOD-incubator at 23°C and 12:12 light/dark. After five days of exposure, 45 slides per treatment were made with root cells from the meristematic region; 300 cells per slide were analyzed through a microscope in order to assess the induction of micronuclei and chromosomal/nuclear alterations (chromosomal bridges and loss, C-metaphase, nuclear bud, etc). Normality and homogeneity of data were assessed by Shapiro-Wilk's and Levene's tests, respectively. Afterward, the data were analyzed by Kruskal-Wallis/Dunn statistical test. The statistical test showed that the highest concentrations of eprinomectin (2.5 µg/g, 12.5 µg/g and 62.5 µg/g) induced statistically significant micronuclei formation and 12.5 µg/g concentration induced chromosomal/nuclear alterations in a significant way. Micronuclei presence is considered a biomarker of genotoxic and chromosomal instability events, which, if not repaired, indicate mutagenic effect. Chromosomal aberrations are characterized both by changes in chromosome structure and in its total number and are also used as a genotoxic biomarker. According to the results, environmental concentrations of eprinomectin can damage the genetic material of *A. cepa*, mainly by means of micronuclei formation in highest concentrations.
Financial Support: FAPESP 17/26214-8

Developing methodologies to understand the degradation and adsorption of macromolecule biopesticides in soil

V. Padricello, D. Werner, Newcastle University / School of Engineering; R. Davenport, Newcastle University / Biological and Environmental Engineering; C. Sinclair, FERA Science Limited; H. Grundy, Fera Science Ltd; J.A. Garratt, Enviresearch Ltd

Pest control represents the main tool for enhancement of agricultural production. Since 1950s, with usage of chemicals (i.e. DDTs and organophosphates), agricultural yields improved to the detriment of environmental quality. To date, conventional pesticides continue to represent a risk for human/animal health and ecological biodiversity because of their environmental persistence and broad-spectrum action. Thus, the development of novel biopesticide which are less harmful, more selective, and thus more eco-friendly, represent a valid alternative in reducing these drawbacks. Therefore, we need to fully assess all new active substances. Global interest in these new pesticides is growing. In the last few years, the sector grew from 3.5% to 5%, acquiring some market share of conventional pesticide. Therefore, one big challenge in agricultural and environmental science is to achieve better knowledge of the environmental fate of novel biopesticides, for example by determining their behaviour in soil. Double stranded RNA (dsRNA) is a biomolecule that triggers the mechanism of RNA interference (RNAi). dsRNA is a protein disruptor, in eukaryotic cells, and it has considerable potential as a tool for insect control. Procedures for its extraction, purification and quantification from soil are essential for environmental fate assessments. We systematically developed a soil extraction procedure recovering roughly 80% of dsRNA from loamy sand soil. During adsorption experiments following the OECD 106 Guidelines for Testing of Chemicals, we found that pre-equilibrating the soil with a low concentration of CaCl2 solution (0.01M) resulted in precipitation of dsRNA (CaCl2 solution + dsRNA), which it might neutralize the charges on the phosphate backbone. This enhanced adsorption as compared to equilibration with distilled water. \n\n

MO140

Emergence timing and voltinism of phantom midges, Chaoborus spp., in the UK.

R. Cockroft, C. Gamblin, AgroChemex Environmental Ltd

The emergence timing of adult *Chaoborus* spp. (Diptera: Chaoboridae) was investigated in outdoor freshwater microcosms in the UK in 2017. Adult *Chaoborus* spp. started emerging on 13 April, 14 days after larvae had been introduced, and reached a peak on 2 May, 33 days after introduction of the larvae. The majority of emergence was completed by 3 June (65 days after establishment). Of the 2027 larvae introduced into four microcosms, emergence ranged from 51.4% to 66.2% with a mean of 60.9%. The majority of emerged insects were *C. obscuripes* (99.68%) and the remainder of those identified were *C. crystallinus* (0.24%). Males appeared to emerge slightly earlier than females. The number of *Chaoborus* spp. life-cycles per year occurring in the UK was studied in six replicate microcosm groups, each containing four individual units. Populations of zooplankton and benthic invertebrates were established in each mesh-enclosed microcosm (containing 200 L of water) with alder (*Alnus glutinosa*) leaves added to provide a substrate for benthic invertebrates. As soon as the first egg rafts were laid in each microcosm these were removed and introduced onto a fresh unit. The first generations in both replicate groups contained both *C. obscuripes* and *C. crystallinus*, although the larvae sampled from the second to fourth generations in these replicates were all *C. crystallinus*. Since only *C. crystallinus* was found in these later generations, the egg-to-egg development time for *C. obscuripes* could not be determined. For *C. crystallinus,* life cycle times from egg-to-egg ranged from 14 days (replicate group 5, first generation) to 56 days (replicate 3, second generation). The results of this study showed that *C. crystallinus* produced up to four discrete generations within the experimental period. The conditions existing in the experimental microcosms may have been unfavourable for oviposition by *C. obscuripes*. This study confirmed that in temperate conditions *C. crystallinus* exhibits a multi-voltine life history.

MO141

Roadmap to recovery: the value of the ecological recovery option (ERO) in higher tier aquatic studies

N. Taylor, Cambridge Environmental Assessments (CEA) / Ecotoxicology; H.S. Schuster, Cambridge Environmental Assessments (CEA) / Aquatic Ecotoxicology; A.C. Brooks, Cambridge Environmental Assessments / Ecotoxicology Risk Assessment; G. Hughes, Cambridge Environmental Assessments; A. Lawrence, Cambridge Environmental Assessments / Institute of Environmental Toxicology

The 2013 EFSA guidance document on tiered risk assessment for plant protection products (PPPs) for aquatic organisms in edge-of-field surface waters allows for regulatory acceptable concentrations (RACs) to be derived using two options. The ecological threshold option (ETO), which allows for negligible population effects; and the ecological recovery option (ERO), where some population-level effects occur, but recovery is demonstrated within an accepted time period. Under the tiered effect assessment, all tiers (tier 1-3) can address the ETO, however, only higher tier studies (tier 3) can be used to derive an ERO. The guidance states that it is feasible to determine an ERO if all issues regarding recovery have been addressed, with all relevant processes that determine population viability and the propagation of effects to the community, ecosystem and landscape level have been considered. However, the use of the ERO endpoint is often member state specific, and the current opinion of the Central Zone (CZ) Ecotoxicology Harmonisation Group is only the ETO approach should be used. Whilst this is certainly the more conservative approach when assigning endpoints and determining RACs, the application of a justifiable ERO-RAC should not be discounted in all cases. One of the key concerns of the CZ is the effect of multiple exposures on the ability of aquatic organisms to recover. Such exposures could occur from multiple inputs from the target crop (e.g. drainflow events), or by exposure to other products used within the same catchment. Since the EFSA guidance proposes an 8-week recovery period, it is possible that multiple exposures may occur during this time. However, the restrictive ETO only approach means that the ERO-RAC is not presented even when recovery is demonstrated to be rapid and the upstream use of compounds with a similar mode of action within that recovery period is unlikely. This poster builds a roadmap of the considerations that should be taken into account when proposing an ERO-RAC for regulatory purposes. This includes the experimental study design (frequent sampling to enable rapid recovery to be demonstrated), analysis of the crops grown and associated product usage within typical agricultural landscapes/catchments and the potential for recolonization of affected water bodies. A major objective of this poster is to generate an active discussion around the use of recovery as an endpoint across industry, policy makers and regulators.

MO142

Robustness of PT values based on the number of tracked animals

A. Guckland, WSC Scientific GmbH; M. Wang, WSC Scientific GmbH / Dept Efate Modelling

For the risk assessment for wild mammals the proportion of an animal's daily diet obtained in habitat treated with pesticide (PT) is frequently used to refine the exposure. The PT values are typically obtained from field studies in which mammals are radio-tracked in the crop of interest and its surroundings. In most studies a rather small number of animals is tracked. However, the habitat use of individual animals may differ from the habitat use of other individuals of the same species and may result in a considerable variability of PT values. Thus, the question arises how much individuals should be radio-tracked to get robust PT values which reflect the behaviour of the whole population. To evaluate the impact of the number of tracked animals on the variability of PT values Monte Carlo simulations are conducted in order to estimate a minimum number of animals which should be tracked in order to obtain a robust PT value.

MO143

Beyond SFO? Residue decline on food in the bird & mammal pesticide risk assessment

F. von Blanckenhagen, D. Nickisch, J. Ludwigs, Rifcon GmbH

Residue decline data on possible food items for bird and mammals are a key factor in order to determine residue uptake to estimate exposure to plant protection products via diet by birds and mammals. Within the risk equation in the current EFSA wildlife guidance residue decline is represented by the multiple application factor (MAF) and the time weighted average factor (TWA) to calculate toxicity exposure ratios. The MAF gives estimation for increase residue uptake for more than one application and the TWA relates to a constantly decreasing residue uptake over reasonable averaging time. Both factors presented in current guidelines covering Ecotoxicology and Environmental Fate are recommended to be calculated with single first order (SFO) kinetics. In other words, a constant decrease of the substance over time. In the current EFSA guidance about risk assessment for bird and mammals details are given how residue decline studies on potential food items should be performed under field conditions. However, often the results of these studies do not follow a SFO kinetic with an acceptable fit. This can be caused by e.g. photolysis, plant growth, residue uptake after application or other compound and matrix-related reasons. Surrogate SFO kinetics as proposed in the modelling decision tree of the current EFSA kinetic guidance document underlay very conservative assumptions with emphasis on the slow phase or DT_{90} values of bi-phasic kinetics. This is because the focus of the current kinetic guideline is on the evaluation of environmental fate studies in soil or water / sediment systems deriving conservative trigger values or endpoints. In contrast, a higher tier birds and mammals risk assessment should reflect real exposure as realistic as possible. Therefore, we tested an alternative kinetic decision tree for wild life residue decline data collected under field conditions to use such data, and propose realistic residue decline data for further use in bird and mammals higher tier risk assessments if the decrease is not following single first order kinetics.

MO144

Vole field effect studies as higher tier refinement - how many voles are enough?

S. Laucht, D. Nickisch, Rifcon GmbH; O. Jakoby, Rifcon GmbH / Regulatory Sciences - Population Modelling and Statistics; T. Grimm, Rifcon GmbH

The current EFSA bird and mammal guidance gives advice on how potential adverse effects of pesticides on wild vertebrates can be assessed. One option for higher tier assessments is to conduct field effect studies to monitor potential acute or long-term effects on small mammal populations using a capture-mark-recapture design. However, the guidance does not give any details on what the study set-up should look like, and studies conducted so far vary considerably. Feasibility and effort, restricted due to time and cost constraints, have certainly an impact on the quality of higher tier data from field studies for small mammal risk assessments. One important element in this typical trade-off between needs and feasibility is the number of consecutive trapping events (i.e. number of days or nights during which small mammals are trapped) within each trapping session resulting in more or less captured individuals. Combined to trapping session, such individual-based data reflect more or less accurately the respective parameters of the populations inhabiting the fields and their surroundings. Here, we examine how many consecutive trapping events are desirable per trapping session to obtain representative data of such populations. We analyse data from different field studies to evaluate the effect of additional trap nights on relevant endpoints (e.g. estimated local population size). In particular, the general variability at a trapping event and the change in the minimal detectable effect sizes are presented. As a second step, we calculate and compare estimates of survival rates, recapture probabilities and abundances using capture-recapture models provided in the MARK tool (version 9.0). Finally, we discuss the implications of the results for the design of small mammal field effect studies.

MO145

HONEY BEES DO NOT LIKE BE(E)ING CONFINED

J. Lenoir, SynTech Research

The currently required setup for evaluation of side effects of plant protection products on honey bees under semi-field conditions is to expose a bee hive to a treated crop for a specific duration in a confined environment (tunnel tents). As large as these tunnels can be, honey bees are enduring stressors challenging most of the time the reliability of the results of the studies. In addition to major stress of confinement, bees must deal with disturbances from multiple transports, visits, samplings and other assessments in a very short period of time. A honey bee colony in its hive represents a well-organized and effective group of insects, which implies an accurate regulation of conditions in the hive (temperature and moisture regulation, balance between colony needs between larval rearing, food consumption and food storing). In the experimental scenario of confinement and multiple assessments, such conditions are easily unbalanced (enhanced changes in environmental conditions, food supply, extensive hive visits, etc). The first observation of the consequence of these changes is the unusual escaping behavior: workers try to escape the tunnels instead of foraging, increasing the mortality rate of the caste dedicated to supply the hive with food. It also represents the first step in the disturbance of the test hives and their possible collapse. In view of these recurrent situations, we assessed a possible way of reducing the main stressor of confinement by testing effects of hive positioning in the tunnels. Usual side effect assessments were performed: colony conditions, mortality and flying activity assessments along with entrance activity assessment in groups of tunnels with different hive positioning. Results of the study provides additional information to improve the experimental semi-field study designs in order to allow side effect tunnel studies to achieve their intended purposes. \n Keywords: honey bees, tunnels, stress, hive position. \n

MO146

The interpretation of non-target arthropod field studies

F.M. Bakker, Bakker Consultant; S. Aldershof, Bioresearch & Evaluation

The execution of non-target arthropod (NTA) field studies generally follows a reasonably standard design as described by deJong et al (2004). In the same document quality/reliability criteria for such field studies are outlined. However, missing is formal guidance on the interpretation of field study results for regulatory purposes. Brock et al. (2015) propose a procedure for aquatic mesocosm studies that combines NOEC's and MDD's in a harmonised way and provide guidance on the reporting of these results. Their procedure to categorize taxa on basis of MDD results and the architecture of both their decision scheme to assess the adequacy of study results for regulatory purposes and their decision scheme to derive effect classes can be amended to fit NTA field studies. With this poster we focus on so-called off-field or off-crop studies. These studies, originally described as "terrestrial mesocosms" (Bakker & Miles, 2006) are also aimed at deriving hypothesis based (NOEC-type) endpoints. An important difference between aquatic and terrestrial mesocosms is the diversity and abundance of taxa and related ecological profiles. Using the same criteria as proposed by Brock et al. (2015) would not provide a balanced evaluation for terrestrial systems, due to the higher diversity in these systems. We propose to use the statistical distribution of Minimum Significant Differences (MSD's) to derive reliability criteria in a taxon-based manner. In addition, we propose to contrast individual MSD's to results obtained from reference treatments to infer whether the exposure scenario was adequate (not finding a reduction when expecting one would imply a potential issue). Together these outcomes may be integrated in a decision scheme to derive effect classifications, akin to the scheme for aquatic studies. With this poster we propose a first draft of such a scheme.

MO147

Impact of Pesticides/ Chemicals on People, Environment and Wildlife Due to Lack of Regulation, Case Study Iran

A. Mahdavi, University of Tehran/ and Sustainable agriculture and environment. / Environmental Toxicology

Pesticide/ chemicals regulations in developing countries lack a proper infrastructure, is not adequately developed and so does not completely support health of people and environment in these countries. The situation is worst in the MENA/ NENA regions due to different problems and so these areas of the planet are suffering a long decade's loss of human and wildlife loss and environmental pollution. Shocking evidences were opened last year by myself in the 2nd CMS preventing poisoning workshop including big losses of migratory birds in toxic wetlands connected to rice paddies and other source/ non source polluted water (Mahdavi, 2017, Toledo Spain for the CMS, CMS COP12 report in Manila). Iran a country very diverse in land, nature and culture continues to be a good market for imported, mostly unknown pesticides and chemicals from West in the past and in recent years from industrial Asian countries like China and India. In the past Iran was getting good information, consultations and support for all its imported products but now this support stopped. As a result, people, environment and wildlife in Iran were exposed to these toxic compounds and their metabolites during past decades. According to my long studies and also a recent field study for this paper pesticide and chemicals regulations is not in a good situation in the MENA/ NENA regions including in Iran. A high percent of wildlife loss is because of deliberate/ undeliberate poisoning and also no care about health of people exposed to these big array of toxic compounds, mixture of compounds with high possibility of synergism and recently added to it biocides. Banning of dangerous pesticides or chemicals is just a gesture with no further enforcement. Diazinon a very harmful insecticide and an undetachable compound from Iranian ecosystems is a good evidence for this. Wide use of other wildlife poisoning compounds like second generation anticoagulant rodenticides which are already banned in most countries, poison-baits, some veterinary drugs like diclofenac and lead poisoning due to lead ammunitions added to this poisoning scenario against the breaking populations of Iran wildlife.

Application of VandA to the Northern Italy

F. Galimberti, ICPS International Centre for Pesticides and Health Risk Prevention / Public Health; G. Azimonti, ICPS International Centre for Pesticides and Health Risk Prevention; A. Moretto, Università degli Studi di Milano

VandA is an innovative and easy-to-use tool to visualize the pesticide surface water contamination, assess the potential pesticide risk and address where to introduce mitigation measures to reduce the contamination and control the risk in the surface water environmental compartment (SETAC Rome 2018; VandA – Visualize and Assess: a tool for the pesticide risk mitigation in surface water). Recently, ISPRA, the Italian National Reference Institute for Environmental Research and Protection, published a National report on pesticides in water resources [1]. The scenario described in the report is drastically negative all over the Italian territory, mainly in the surface and ground water of the Po Plain in the

North of Italy. This resulting analysis highlights a critical situation which seems in contrast with the local results which shows how the latest strategies implemented by the four main Regions of the Po plain are continuously improving the agricoltural environment, enchancing the ecological state of water resources, in line with objectives of the Directive 2009/128/CE on establishing a framework for Community action to achieve the sustainable use of pesticides. Aim of the present work is to run the VandA tool on pesticide residue data in surface water of the four main Regions in the Po Plain, in order to show the trend of contamination in the last years and how the mitigations applied are improving status of surface water in agricultural areas. [1] Rapporto nazionale pesticidi nelle acque dati 2015-2016. Edizione 2018. 282/2018. ISBN: 978-88-448-0848-8

Mit-Mesw

F. Galimberti, ICPS International Centre for Pesticides and Health Risk Prevention / Public Health; S. Otto, Italian National Research Council; G. Azimonti, ICPS International Centre for Pesticides and Health Risk Prevention; A. Moretto, Università degli Studi di Milano

The authorization process for plant protection products (PPP) requires, among others, the assessment of surface water contamination deriving from the use of each product. In some cases, the application of PPP might present some critical features for the aquatic environment and the application of mitigation measures to reduce the exposure are mandatory to protect the aquatic life. In addition, on a larger scale, the adoption of mitigation measures could bring to an improvement of the quality conditions of natural resources, with valuable social and economic advantages for the agricultural sector. Surface water contamination by PPP occurs mainly from three different routes: runoff, spray drift or drainage. In Italy, due to the characteristics of the territory, runoff and spray drift are the two major routes of contamination. Different pesticide risk mitigation measures can be adopted to reduce the exposure coming from these two routes of contaminations: anti-drift nozzles, specific equipment, buffer strips (vegetated or not), hedgerows etc. The combination of different mitigation measurements can produce a high level of mitigation. These huge amount of combinations cannot be included into a label; therefore, a simplified solution was adopted in Italy. In the label, the mitigation coming from modelling, performed according EU criteria is indicated together with the percentage of reduction of dose necessary to obtain a safe use. On the other hand, a harmonized value of reduction has been assigned to each possible mitigation measure. These values are in line with those proposed by the MAgPIE project (Mitigating the Risk of Plant Protection Products in the Environment), with other research projects (i.e. STRIPE-Ireland) and with some national researches and expert judgement. The possible mitigation measures applicable in Italy have been listed in a guidance document and an easy-to-use tool has been developed. The tool is called Mit-Me$_{sw}$ (MITigation MEasures for Surface-Water). This tool, through a series of combo-menus and images, aims at helping farmers in choosing the best equipment and agronomic practices to mitigate the pesticide risk, and pesticide risk assessors in quantifying the percentage of risk reduction due to each singular/combined adopted mitigation measures.

López de Alda, Institute of Environmental Assessment and Water Research IDAEA-CSIC / Department of Environmental Chemistry

Water quality in Europe is under constant pressure and this represents a big threat for our drinking water resources. In this context, the EU project WaterProtect aims at developing new solutions and tools to effectively uptake and identify management practices and mitigation measures to protect drinking water resources threatened by agricultural, urban and industrial pressures. This will be conducted in seven action labs spread in the European territory that represent different realities and problems in terms of water governance. From the experiences in the different action labs, lessons learnt will be upscaled so that they can be applied to improve water governance in any other location. The lower basin of the Llobregat River (NE Spain) is one of the WaterProtect action labs. This area is located in a densely populated area, as it is the metropolitan area of the city of Barcelona. Because of this, groundwater is intensively exploited for different uses (production of drinking water, agriculture, and industrial activities), and the river water serves as a source for drinking water production. Overall, water quality in the area is highly impacted by urban and industrial activities and to a less extent by agriculture, also present in the area. In the framework of WaterProtect, a multi-actor participatory approach was used to identify water management needs in the lower Llobregat River basin and to engage different water actors in water governance. A participatory monitoring approach was used to design a monitoring campaign to cover knowledge gaps regarding pesticides and nitrates in the area. A practical collaborative open access tool that integrates water quality data has been created and will be internet freely available to the general public. Finally, in order to improve water quality in the area and reduce the impact of agricultural activities, selected best management practices are being promoted among farmers and two techniques for biorremediation of water polluted with pesticides are being tested. *Acknowledgments:* This work has received funding from the Government of Catalonia (2017 SGR 01404), the Spanish State Research Agency (AEI) and the European Regional Development Fund (ERDF) through the project BECAS (CTM2016-75587-C2-2-R), and the EU Horizon 2020 Programme (No. 727450). Modelling real VFS experiments with a new VFSMOD version - calibration and uncertainty analysis with DREAM-ZS

S. Reichenberger, DR. KNOELL CONSULT GmbH / Environmental Fate / Modelling / GIS; R. Sur, C. Kley, Bayer AG - Crop Science Division / Environmental Safety; S. Sittig, knoell Germany GmbH / E-Fate Modelling; S. Multsch, knoell Germany GmbH

The most widely implemented mitigation measure to reduce transfer of pesticides and other pollutants to surface water bodies via surface runoff are vegetative filter strips (VFS). To reliably model the reduction of surface runoff, eroded sediment and pesticide inputs into surface water by VFS in a risk assessment context, an event-based model is needed. The most commonly used dynamic, event-based model for this purpose is VFSMOD. While VFSMOD simulates reduction of total inflow (?Q) and reduction of incoming eroded sediment load (?E) mechanistically, the reduction of pesticide load by the VFS (?P) has until recently been calculated exclusively with the empirical Sabbagh equation. The latest version of VFSMOD (v.4.4.0) includes further pesticide trapping options, notably the Sabbagh equation with user-defined regression coefficients and a regression-free mass-balance approach. The new VFSMOD version was systematically tested against real experimental data. Four studies with 16 hydrological events and 31 combinations of hydrological event and compound were selected from the experimental data compiled by Reichenberger et al. (2019), representing different levels of data availability and uncertainty. A first set of simulations was conducted with parameterization according to SWAN-VFSMOD and the three pesticide trapping options mentioned above. The Sabbagh equation with optimized coefficients from Reichenberger et al. (2019) and the original Sabbagh equation overestimated pesticide trapping efficiency ?P for the low range of measured ?P, while the mass balance approach yielded the most conservative results. These observations were due to an overestimation of ?E with the SWAN-VFSMOD parameterization. The simulation results suggest that the SWAN-VFSMOD parameterization of saturated hydraulic conductivity is too conservative, while the parameterization of sediment filtration is too optimistic. In a second step, a maximum-likelihood-based calibration and uncertainty analysis was performed for each hydrological event and the target variables ?Q and ?E with the DREAM-ZS algorithm. One aim of the DREAM analysis was to help improve the parameterization methodologies for the infiltration and sediment filtration modules for regulatory VFS scenarios. Subsequently, the three pesticide trapping equations were applied in predictive mode to elucidate which equation performs better in which situation (e.g. soil type, Kd, characteristics of runoff/erosion event).

MO152

The future of risk assessment is not risk assessment: could improved farmland biodiversity mitigate marginal risk assessments?

A. Lawrence, Cambridge Environmental Assessments / Institute of Environmental Toxicology

Recent experience suggests that evaluations of environmental risk assessments for plant protection products (PPP) by Member States/EFSA are becoming more conservative. This may be attributable to issues such as exposure to multiple stressors at the field or catchment level. There is also concern that farmland biodiversity is impoverished and that even minor, transient, toxic insults cannot be tolerated. Media reports on biodiversity loss and negative effects of PPP may add to this. Notifiers are investing more and more resources in higher tier risk assessments, such as multiple field studies. Increasingly, however, any uncertainty associated with the risk assessment or studies is sufficient to conclude no acceptable risk or no safe use, despite a considerable weight of evidence to the contrary. With the loss of neonicotinoids we may turn to older chemistry, which is also under threat from these issues. There is a need, therefore, to explore ways in which such concerns may be overcome, to keep key crop protection tools on the market while also ensuring a high level of environmental safety. There is strong evidence from various demonstration farms and industry initiatives that intensive agriculture and PPP use can go hand in hand with vastly improved biodiversity –

examples will be provided. This can be achieved through crop selection, in-field measures and intelligent margin management. This therefore begs the following questions: If resources were invested in measures to demonstrably improve farmland biodiversity, could concerns regarding the impact of transient, minor effects of PPP be alleviated? Could a more resilient agroecosystem be considered better able to buffer minor effects of PPPs, which increasingly result in recommendations of non-approval for key crop protection tools? The means to achieve this already exist and were summarised in a recent report for the MagPIE project (Hackett & Lawrence, 2014). An important option with significant potential is multi-functional field margins (MFFM). MFFM can mitigate exposure of off-field habitats through the attenuation of spray drift and/or run-off, while also being managed to promote biodivesity. Label requirements for management of no-spray buffers and filter strips offer a mechanism to ensure compliance. Other available tools offer in-field benefits. This poster aims to further discussion around how we may maintain access to key PPPs by promoting farmland biodiversity using existing management options.

MO153
Changes foreseen according to EMAs new draft guideline on the environmental risk assessment (ERA) of medicinal products for human use
R. Wess, Innovative Environmental Services (IES) Ltd. / Regulatory Consulting
The Committee for Medicinal Products for Human Use (CHMP) has issued the ERA new draft guideline (EMEA/CHMP/SWP/4447/00 Rev. 1) on 15 November 2018. As the commenting is possible until the 30 June 2019 (deadline for comments) the poster intends to summarize some of the most important changes in order to facilitate the timely submission of comments. Some issues, being in contradiction to the recent questions and answers document of 2016 (EMA/CHMP/SWP/44609/2010 Rev. 1) are that generally all HPLC / OPPTS methods are phased out.\nMany amendments represent the scientific or regulatory progress:\n- NOEC phased out except for limit studies (thus always EC10 calculation required)\n- Earthworm reproduction study instead of the acute test\n- Study rating and summaries required\n- Reference/Harmonisation to/with Water Framework Directive (WFD) Guidance for deriving EQS (Guidance Document No.27, Technical Report-2011–055)\n- Formal submission item characterisation\n- Full dataset for pH-dependency on lipophilicity (Dow); i.e. determination Dissociation constant and Kow (of the neutral molecule)\n- Requirement to undisclose the relation of the assessor to the applicant\n- Specific study demands for potential endocrine disruptors and antibiotics\n- Use of DT50 values for the EU annual average temperature of 12 °C\n- Sediment organism effect testing switched to phase II, Tier A & increased assessment factor of 100 for Chironomid life cycle EC10\nFurthermore some changes signify a change in the structure of the assessment approach:\n- PEC correction based on marketing data is phased out\n- Thus it is much more important to have data allowing the derivation of the fraction of substance excreted (F excreta) - this has impact on potentially already ongoing pharmacokinetic studies\nSome dubiety remain due to the absence of any hint on an acceptable approach for the calculation of an activation energy for use in the Arrhenius equation (correction of DT50 to 12 °C). Also no standard for the study summaries is given however application of the OECD templates is nearby. Hyalella is not mentioned in the guidance any more, but due to the reference to WFD may be regarded anyhow.

MO154
Incorporating bioavailability in aquatic risk assessment of pharmaceuticals
K. De Schamphelaere, Ghent University (UGent) / Environmental Toxicology; L. Vandeneynde, Arche consulting; F. Verdonck, ARCHE; P. Van Sprang, Arche consulting
About 75% of human pharmaceuticals are ionisable, with the ratio between neutral and charged forms of API being determined by both the environment (pH) and the acid-base behavior (pKa) of the active pharmaceutical ingredient (AP)I. Theoretical considerations and some recently published empirical work indicate that the unionized form of an ionizable API is usually more easily taken up, more bioavailable and more toxic than the ionized form. However, although the effect of pH on API availability can amount to one order of magnitude per pH unit change, we are unaware of any regulatory risk assessment framework that takes this into account. For instance, neither the new draft guidance document on human pharmaceutical risk assessment nor the derivation of environmental quality standard (EQS) under the water framework directive (WFD) considers bioavailability. This is much in contrast with what is now common practice in metals risk assessment, where effects on ecotoxicity of factors such as pH, DOC and waters hardness are accounted for using semi-mechanistic biotic ligand models (BLM). Here, focusing on pH as a factor, we use a case study with two pharmaceuticals, the anti-inflammatory drug diclofenac (acid, pKa=4.0, more ionized at increasing pH) and the beta-blocker propranolol (base, pKa=9.4, more ionized at low pH), to show how the predicted no effect concentration (PNEC) or EQS can vary across Europe (based on the FOREGS database), if bioavailability, through ionization, is take into account. The EQS for diclofenac is currently at 100 ng/L (based on histological effects on rainbow trout in a test at pH 7.4), but would range between 10 to 794 ng/L (10-90th percentile) if only the unionized form is assumed bioavailable, with many low values occurring in Northern Europe (mostly low pH). Similarly, propranolol, with a reported PNEC of 200 ng/L (based on a sea urchin test at test pH of 8.1), shows varying PNEC values from 130 to 9555 ng/L (with most low values occurring in Southern Europe, high pH). Our analysis shows that not taking into account bioavailability can result in both under or overestimation of true risks, depending on pH of the ecotoxicity tests, acid-base behavior of the API, and geographic location (or local pH). Taking into account bioavailability would improve this problem and could help better prioritization of API in terms of risk reduction.

Effect Modelling for Regulatory Risk Assessment: Current Applications and Future Directions (P)

MO157
Use of algae modelling as a tier 2c refinement within the framework of the EFSA TKTD opinion
J. Witt, Bayer AG / Environmental Safety; J. Hager, Bayer Ag; E. Bruns, Bayer AG, Division Bayer CropScience / Ecotoxicology; T. Preuss, Bayer Ag / Environmental Safety
Algae growth inhibition tests measure growth inhibition for constant exposure to a chemical. Real-world exposure is often much more variable. The use of a mathematical algae model offers the opportunity to predict the effects of time variable exposure in silico, and therefore improves the realism of risk assessment. While effect modelling for risk assessment was performed and evaluated on a case by case basis in the past, the recently published EFSA TKTD opinion has made an important step towards a standardised effect modelling framework in risk assessment. Evaluation of the algae model of Weber et al. within the TKTD opinion yielded a two-sided result: the predictive power of the model was confirmed under constant and optimal conditions. However, the flow-through test design used for validation was identified as the largest drawback for implementing the model in risk assessment, because of its non-standard design that has not been ring tested. Consequently, an update of the current practice of using the algae model in combination with experimental data will be required to increase regulatory acceptance. We show how the algae modelling workflow may be adapted to fit into the framework of the TKTD opinion. This includes a proposal for an alternative test design for validation experiments. We then show how the model can be used as a tier 2c refinement in risk assessment.

MO158
Proposal how to use measured exposure concentrations in calibration and validation experiments as input for TKTD models
J. Witt, Bayer AG / Environmental Safety; S. Heine, Bayer Ag / Effect modelling; Z. Gao, A. Gergs, Bayer AG; E. Bruns, Bayer AG, Division Bayer CropScience / Ecotoxicology; T. Preuss, Bayer Ag / Environmental Safety
With the increased use of TKTD models in risk assessment, there is an increasing need for standardised procedures. Many recommendations have recently been given in the EFSA TKTD opinion. One point, however, still remains open: how should the measured exposure concentrations be used as an input for TKTD models? This may seem straightforward at first sight. However, exposure concentrations may vary over time in the experiments, and there are different ways to address the variability, e.g. arithmetic mean, geometric mean, a fitted decline curve, or linear interpolation. Different approaches may be more or less appropriate in different situations. The chosen approach may have a huge effect on the temporal exposure pattern and may therefore have a considerable influence on the final outcome of the modelling. We propose a standardised default procedure how to use measured exposure concentrations in calibration and validation experiments as an input for TKTD models, respecting existing guidance (AGD corrigendum). These procedures are being used within Bayer for several years and proved to be applicable to a broad data set from different species (algae, macrophytes, aquatic invertebrates and fish). The recommended procedures depend on experimental setup (flow-through, semi-static, static) stability of the test item quality and availability of data Well-reasoned exceptions may be made on a case-by-case basis.

MO159
Scientific opinion about TKTD models to assess risks of time-variable exposure for pesticides in edge-of-field surface waters
A. Focks, Wageningen Environmental Research / Environmental Risk Assessment Team; M. Arena, EFSA - European Food Safety Authority / Pesticides; T. Brock, Wageningen Environmental Research / Environmental Risk Assessment Team; N. Cedergreen, University of Copenhagen / Plant and Environmental Sciences; S.

Charles, University Lyon 1 / Laboratory of Biometry and Evolutionnary Biology; S. Duquesne, German Environment Agency; A. Ippolito, EFSA - European Food Safety Authority / Pesticides Unit; M. Klein, Fraunhofer IME / Ecological chemistry; M. Reed, HSE; I. Teodorovic, University of Novi Sad / Department of Biology and Ecology, Laboratory of Ecotoxicology (LECOTOX)
In 2018, the Panel on Plant Protection Products and their Residues (PPR) of the European Food Safety Authority (EFSA) published a scientific opinion (SO) on the state of the art of Toxicokinetic/Toxicodynamic (TKTD) models in regulatory risk assessment of pesticides for aquatic organisms (*EFSA PPR, 2018. EFSA Journal 2018;16(8):5377*). This SO gives an overview and evaluates the state of science of existing TKTD models for lethal and sublethal effects on animals and primary producers. It is concluded that GUTS models (General Unified Threshold models of Survival), which account for lethal effects on animals, are well established and can be used in the risk assessment scheme to assess the risk of time-variable exposure. DEBtox models (Dynamic Energy Budget toxicity models) account for sublethal effects of pesticides on growth and reproduction. They are considered to be in an advanced state but not yet ready to be used for regulatory risk assessment; the SO provides some suggestions for improving them and making them more suitable for this purpose. Models accounting for the effects of pesticides on primary producers have been also evaluated. Currently, species–specific models have been developed for *Lemna* sp., *Myriophyllum* sp, and two algae species. A conclusion about the state of science for these species-specific models suggests that the *Lemna* model is suitable for use in regulatory risk assessment, given that some remaining aspects of model applications such as better documentation of optimisation methods and sensitivity analyses are improved, while some shortcomings prevented to recommend the *Myriophyllum* and algae models as fit for purpose. The poster gives an overview about the principles of these different TKTD models and summarises the conclusions presented in the SO.

MO160
Beyond GUTS: DEBtox and primary producer TKTD models in ERA of pesticides
M. Reed, HSE; M. Arena, EFSA - European Food Safety Authority / Pesticides; T. Brock, Wageningen Environmental Research / Environmental Risk Assessment Team; N. Cedergreen, University of Copenhagen / Plant and Environmental Sciences; S. Charles, University Lyon 1 / Laboratory of Biometry and Evolutionnary Biology; S. Duquesne, German Environment Agency; A. Focks, Wageningen Environmental Research / Environmental Risk Assessment Team; A. Ippolito, EFSA - European Food Safety Authority / Pesticides Unit; M. Klein, Fraunhofer IME / Ecological chemistry; I. Teodorovic, University of Novi Sad / Department of Biology and Ecology, Laboratory of Ecotoxicology (LECOTOX)
In 2018, the Panel on Plant Protection Products and their Residues (PPR) of the European Food Safety Authority (EFSA) published a scientific opinion on the state of the art of Toxicokinetic Toxicodynamic (TKTD) models in regulatory risk assessment of pesticides for aquatic organisms (*EFSA PPR, 2018. EFSA Journal 2018;16(8):5377*). In this scientific opinion it is concluded that Dynamic Energy Budget theory for ecotoxicology (DEBtox models) and models for some primary producers are not yet sufficiently developed to use them in the risk assessment scheme when assessing the risks of time-variable exposure. This poster considers how these models could be used as a Tier-2 option for environmental risk assessment (ERA) and what still needs to be done to permit routine use. The DEBtox modelling framework, based on the DEB theory, is developed to address individual level lethal and sublethal chronic effects. It may be an appropriate approach to use in the refined chronic risk assessment scheme for aquatic invertebrates, fish and aquatic stages of amphibians, particularly when sublethal endpoints are most critical in chronic toxicity tests. Both the physiological DEB part of DEBtox models and their TKTD part need to be fully evaluated to use the model. Three primary producer models are considered, *Lemna,* algae and *Myriophyllum*. The *Lemna* model appears suitable for use in risk assessment to evaluate effects of time-variable exposure on *Lemna* growth; however, some remaining aspects of the model require further work to make applications acceptable for use in regulatory risk assessment. The algae model is also described but currently its largest drawback is that the flow-through experimental setup, used for model validation to simulate long-term variable exposures of pesticides to fast growing populations of algae, has not yet been standardised. The *Myriophyllum* model looks promising, but currently there is insufficient information available to recommend its use for ERA. For all the models presented, the poster aims to provide recommendations for future developments that will help the models be accepted for regulatory risk assessment of pesticides.

MO161
User-friendly software for survival modelling with GUTS
T. Jager, DEBtox Research / Dept of Theoretical Biology; M. Wang, WSC Scientific GmbH / Dept Efate Modelling; R. Ashauer, University of York / Environment
Mechanistic effect models are rapidly gaining interest in the context of environmental risk assessment. In 2018, this interest culminated in a dedicated EFSA opinion on toxicokinetic-toxicodynamic (TKTD) models for use in aquatic risk assessment of pesticides. This opinion focussed on three modelling frameworks; for the endpoint survival, the focus was on GUTS (the General Unified Threshold model for Survival). Since the EFSA opinion judged GUTS to be "ready to be used in risk assessment", there is now a pressing need for robust and user-friendly software to perform analyses with this model, following the proposed workflow in the opinion. In a Cefic-LRI funded project, we are currently developing such a software. The resulting software will be able to perform the procedures for calibration, testing and model predictions as outlined in the EFSA opinion. Furthermore, it will perform these analyses with minimal demands on user experience in modelling and statistics. However, this software will not be restricted to risk assessment of pesticides. It can also be used for other tasks, such as the derivation of classical LC50 values (as function of time) from standard and non-standard toxicity data, using all of the observation on survival over time. Specifically, the software will enable meaningful calibration to toxicity data that result from tests with time-varying exposure, which cannot be achieved using traditional dose-response curves. The software is planned to be released by the end of 2019, but in this contribution, we provide a sneak preview of the software's layout, algorithm, functionality and look.

MO162
On the best practice for DEB(tox) parametrisation for regulatory risk assessment
B. Goussen, IBACON GmbH / Ecological Modelling; S. Charles, University Lyon 1 / Laboratory of Biometry and Evolutionnary Biology; A. Gergs, Bayer AG - Crop Science Division / Department of Environmental, Social and Spatial Change; T. Preuss, Bayer Ag / Environmental Safety
The development of a consistent and relevant modelling approach for the regulatory environmental risk assessment of sub-lethal effects of chemical compounds is a major challenge that starts to be addressed. Following the EFSA Scientific Opinion on the state of the art of Toxicokinetic/Toxicodynamic (TKTD) effect models (*EFSA PPR, 2018. EFSA Journal;16(8):5377*), models based on the Dynamic Energy Budget theory adapted for ecotoxicology are valuable tools for environmental risk assessment. In principle, such models should be fully calibrated and validated, considering both physiological and toxicological parameters all together. Nevertheless, to keep them simple and manageable, a first step towards their full acceptance by stake-holders would be to have the physiological parameters of DEB-based models independently approved by a competent expert team, and, in a second step, to only calibrate toxicological parameters from toxicity test data. Despite its simplicity, this approach bears a number of statistical flaws and might not allow for sound forward predictions. Therefore, we propose to test to what extent separating calibration of physiological and toxicological parameters may impact predictions of sub-lethal effects due to chemical compounds. To do so, we need to define appropriate calibration framework for the standard DEB model coupled with stress functions. As a first step, we identified three possible frameworks (i) The strict separation view, i.e., fix the physiological parameters to their mean regulatory accepted values and get estimates of toxicological parameters only from experimental toxicity test data then use fixed mean values of physiological parameters and estimated toxicological parameters including their uncertainty for predictions; (ii) the statistical view, i.e., use the physiological parameters as input priors to perform full Bayesian inference and get estimates of both the physiological and toxicological parameters, then use them associated to their uncertainty for predictions; or (iii) a compromise, i.e., use the physiological parameters as input priors to perform full Bayesian inference and get estimates of both the physiological and toxicological parameters, but use the fixed mean regulatory accepted values of the physiological parameters together with the estimated toxicological parameters including their uncertainty for predictions. The analysis of each of these approaches is here presented and discussed.

MO163
Dynamic energy budget modelling of Daphnia magna population dynamics - validation examples
A. Gergs, Bayer AG - Crop Science Division / Department of Environmental, Social and Spatial Change; K. Rakel, Research Institute gaiac / gaiac- Research Institute for Ecosystem Analysis und Assessment
In the context of the prospective environmental risk assessment for pesticides, individual-based population models (IBMs) allow quantitative predictions on how populations perform under chemical stress based on individual level toxicity test results. When integrated with toxicokinetic-toxicodynamic (TK-TD) models, the IBMs can be used e.g. for the evaluation of potential population level risks that may arise from time-variable exposures on aquatic organisms such as *Daphnia magna*. As regards TK-TD models, dynamic energy budget (DEB) models are particularly suitable to deal with effects of chemicals on life-history traits related to growth and reproduction, while the general unified threshold model of survival (GUTS) accounts for lethal effects. In this regard, we will showcase validation examples from a DEB based IBM, parametrized for *Daphnia magna*. For validation, we confront model predictions with population level data from various control conditions as well as for exposure situations resulting in sublethal or lethal effects.

MO164

Dynamic energy budget modelling of macroinvertebrate population dynamics - validation examples from different species

A. Gergs, Bayer AG - Crop Science Division / Department of Environmental, Social and Spatial Change; D. Liesy, Research Institute gaiac; H. Selck, Roskilde University / Dept Science and Environment; A. Palmqvist, Roskilde University / Department of Science and Environment

In the ecological risk assessment of chemicals, mechanistic effect models provide the possibility to extrapolate effects to untested scenarios. In particular, individual-based population models (IBMs) are able to make quantitative predictions on how populations perform under chemical stress based on individual-level toxicity testing. In the past, IBMs have usually been designed for specific species and have, thus, been perceived as being too complex to understand mainly due to the variety of existing approaches. The developments of more standardized model designs will facilitate their acceptability. Dynamic energy budget (DEB) models are suitable to describe life-history traits related to growth and reproduction and, when integrated in an IBM framework, allow simulating population dynamics. DEB models have been developed for a large variety of species and parameters, code and underlying data are available from the so called add-my-pet collection. We here show, for the example of different aquatic macroinvertebrates, that the same basic DEB -IBM, only changing parameter values and initial conditions (to match the experimental setup used for comparison of data and model output), is able to adequately predict population dynamics.

Preuss, Bayer Ag / Environmental Safety

In the context of the prospective environmental risk assessment for pesticides, toxicokinetic-toxicodynamic (TK-TD) models are useful e.g. for the evaluation of potential risks that may arise from time-variable exposures on aquatic organisms. Dynamic energy budget (DEB) models are particularly suitable to deal with effects of toxic chemicals on life-history traits related to growth and reproduction. DEB models for chemical effects consist of two modules, a ‘physiological’ module that describes the acquisition and use of energy for growth and reproduction, and a TK-TD module that accounts for chemical stress. As regards the physiological module, the add-my-pet collection hosts DEB models, parameter estimates and underlying data for a broad range of species, including *Daphnia magna*. When combined with the physiological DEB model as derived from the add-my-pet collection, the TK-TD module can be used to analyze data from *Daphnia magna* reproduction test. A species and compound specific model validation is key to reliable applications within the prospective environmental risk assessment. In this regard, we will showcase a validation example for both the physiological DEB model as well as TK-TD module using Trifloxystrobin as an example.

Mixture toxicity with an individual-based model on the dynamic energy budget theory: effects of Cu and Zn on Daphnia magna populations

K. Vlaeminck, Arche consulting / GhEnToxLab; K. Viaene, ARCHE; P. Van Sprang, Arche consulting; K. De Schamphelaere, Ghent University (UGent) / Environmental Toxicology

The current regulatory framework of risk assessment considers the effects of single substances that are assessed through standardized laboratory tests, e.g. the 21-day *Daphnia magna* reproduction test. However, in the environment, individual organisms are being exposed to mixtures of chemicals. Protection goals in EU legislation (e.g. Water Framework Directive) state that protection of populations is needed to maintain ecosystem functioning. In our research, we developed an Individual-Based Model of the Dynamic Energy Budget theory (DEB-IBM) to predict effects of metal mixtures on *Daphnia magna* populations. The DEBtox model was calibrated using apical effects (i.e. growth, reproduction and survival) of Cu and Zn assessed in standardised tests. To validate our model and determine the most appropriate mixture toxicity mode at the population level, a population experiment (75 days) with *D. magna* exposed to Cu and Zn (both single and mixtures) was performed. We tested three implementations of mixture toxicity in DEB-IBM: independent action (where effects of the compounds are considered independent), concentration addition (where the compounds have the same toxic mode and act as dilutions of each other) and effect addition (where the compounds have the same toxic mode but effect levels are summed). Each implementation was evaluated for predictability against the data of the population experiment using the normalised mean square error (NMSE). All three implementations perform well compared to the data, indicating that none of the mixture models is preferred at the population level. We extrapolated the experiment with DEB-IBM to untested concentrations and determined effect levels for Cu and Zn based on equilibrium population density. The effect levels of the three mixture toxicity implementations were compared to assess the applicability of our model for mixture toxicity risk assessment at the population level. The current implementation of mixture toxicity in DEB-IBM could accurately predict mixture toxicity effects observed in a population experiment. The concentration addition model seemed to be the more conservative mixture toxicity mode. More fine-tuning and comparison with experiments is needed to further validate our approach and increase confidence in the predictions.

MO167

Implementing realistic biological variability in an individual-based Dynamic Energy Budget model

J. Koch, GhEnToxLab (Ghent University) / Applied Ecology and Environmental Biology; K. De Schamphelaere, Ghent University (UGent) / Environmental Toxicology

One of the biggest advantages of individual-based population models (IBMs) is the possibility to simulate biological variation among individual animals. Inter-individual variation is known to promote the ecological success of populations by making them more resilient to environmental changes and stress events. While inter-individual variation can be measured in virtually all populations, reproducing such variation in population models accurately is not always straightforward. That is mainly because variation can be measured in apical endpoints like development time, size at a certain age or life stage, or reproduction success, but not on the underlying physiological parameters of the organism. In IBMs that make use of the Dynamic Energy Budget (DEB) theory, the development of an organism depends on 12 primary parameters, all of which potentially vary among individuals to some extent. While previous studies included stochastic scatter for individual parameters (one at a time), the degree of variation in this parameter has always been chosen rather arbitrarily. In this study we used experimental data on the development time and brood sizes of the copepod *Nitocra spinipes* reared at control conditions to make realistic estimates of the variability in DEB parameters for this species. As a first step, a global sensitivity analysis was performed to identify the parameters that are linked most closely to the observed endpoints. Subsequently, stochastic scatter was introduced to these parameters by drawing them from a probability distribution (multiple distribution types were tested and compared ranging from uniform to log-normal distributions). The degree of variation per parameter was adjusted by means of an optimisation algorithm that makes use Monte Carlo simulations. The Kolmogorov-Smirnov test statistic was used to assess the difference between measured versus simulated data distributions. A simulated annealing approach was used to minimise the difference and hence optimise the variation parameters.

Toxicokinetic and Toxicodynamic modelling of the fungicide tebuconazole in the benthic organism Chironomus riparius

N. Creusot, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Chemistry; M. Lefranc, Ecotox Centre CH; C. Casado-Martinez, Centre Ecotox; J. Hollender, Eawag / Environmental Chemistry

Sediment is a sink for thousands of man-made chemicals that may impact structure and functioning of this key compartment, raising need to evaluate associated risk for aquatic organisms. In this context, one major issue is to better characterize the uptake and biotransformation of the contaminants in the organisms in order to identify the internal dose that may trigger a biological response. For this purpose, Toxicokinetic-Toxicodynamic models are increasingly used. In the present study we investigated for the fate of the antifungal tebuconazole in the benthic organism *Chironomus riparius* that is used as a model in regulatory hazard assessment. To this end, chironomids were first exposed to artificial sediment spiked at 1000 µg/g d.w. in order to identify its biotransformation product(s) using HRMS/MS. Then, TK experiments were implemented consisting in exposure to tebuconazole at 200 µg/g d.w. during 24h of uptake followed by 96h of depuration. An one compartment model was used to describe the time course of the tebuconazole and the major identified metabolite. This revealed particular fast uptake (i.e. steady state reached in one hour) and very fast depuration of the chemicals. Such TK could be related to the tebuconazole bound to the ingested sediment, still present in the organisms during the analysis due to the absence of a gut purging phase. Nevertheless, the identification of an oxidative product of the tebuconazole, demonstrated that biotransformation is also involved in the fate of this fungicide in chironomids and therefore bioavailable. Then, we implemented TD experiments by exposing chironomids to a concentration range of tebuconazole (50-100 mg/g) during 14 days and growth and survival were assessed along all experiment. From these data, we implemented a General Unified Threshold model for Survival (GUTS) based on both stochastic and independent death hypotheses that highlighted decreasing LC50 values along the exposure time. The results also showed reduced growth with increasing exposure time and concentration. Although these data were integrated in a DebTox model, the growth curves did not fit so well with actual values, likely because of the use of the Von-Bertalafny growth model that is not suitable to describe the growth of insects. Nevertheless, effect on the growth raised the question of the involved mechanism(s) in non-target species and its conservation along evolution since such effect of the tebuconazole is also reported in fish.

Screening for protonophoric uncouplers
A. Ebert, Helmholtz Centre for Environmental Research UFZ; K. Goss, Helmholtz centre for environmental research - UFZ / Analytical Environmental Chemistry
Test procedures and their evaluation in current regulatory risk assessment are mainly focused on neutral (uncharged) compounds. Yet, a substantial part of the compounds to be assessed is ionisable. For these, pH-dependence of toxicity is an important factor. One such pH-dependent effect is protonophoric uncoupling, where a weak acid shuttles protons H^+ across the inner membrane of the mitochondria, and thereby decreases/dissipates the proton gradient created by proton pumps of the respiratory chain. This gradient is essential for ATP-synthesis, and its dissipation leads to a toxic effect. Due to recent advances in the prediction of anionic permeation through lipid bilayers, we were able to develop a purely mechanistic biophysical prediction model of pH-dependent uncoupling toxicity. Our model describes a steady state situation, where the net flux of the protonophore across the membrane is zero. At the same time, we assume a toxic effect to occur once the flux of shuttled H^+ reaches the same order of magnitude as the opposing flux of H^+ created by the proton pumps. Important input factors are physiological data, like the pH- and potential-gradient across the mitochondrial membrane, as well as the fractionation (pKa) and the permeability of the weak acid. The core input is the anionic permeability of the uncoupler. At this point, our mechanistic model is well suited to predict minimal toxicities of ionisable compounds, as well as pH-dependencies and their direct cause (like ion trapping or limitations by the neutral permeability). But to avoid underestimation of toxicity due to uncoupling, heterodimer permeation will have to be included in the model. The advantage of our model over already existing quantitative structure-activity relationships (QSARs) is the ability to account for pH- or potential-gradients across the membrane. Also, the mechanistic nature of the model allows to draw direct conclusions on the factors that limit the uncoupling activity. Furthermore, because the mechanistic model should not be limited to certain classes of chemicals, it can be used as a screening tool to check large databases for possible uncouplers, and predict their pH-dependent uncoupling toxicity. This may facilitate the right choice of relevant pH ranges of toxicity assays.

Modelling vs. experimental testing of chemical toxicity of environmental mixtures of pesticides on freshwater algae
K.A. Sandblom, T. Backhaus, University of Gothenburg Sweden / Department of Environmental and Biologigal Sciences; N. Corcoll, University of Gothenburg, Sweden / Biological and Environmental Sciences
Mixture toxicity modelling has emerged as a promising tool for mixture toxicity risk assessment, however, such models have not been fully validated against experimental testing. In our project we want to take a step further and compare risk assessment from mixtures of pesticides on algae between modeling and experimental testing using real environmental mixtures, and compare risk assessment models based on a single species-oriented approach vs. a species sensitivity distribution (SSD) approach. In this study, a field sampling was carried out in three agricultural streams, presenting different levels of pesticide pollution (SE Sweden), in September and October 2016. For each sampling site, pesticide levels in surface water and from passive samplers (e.g Chemcatchers) were analyzed. The risk of identified pesticide mixtures on freshwater algae was assessed by mixture toxicity modelling and with ongoing laboratory ecotoxicity tests using the field passive sampler extracts. Our ecotoxicity tests are performed in an optimized semi high-throughput assay (24/96-well microplates) for the freshwater algae *Raphidocellis subcapitata* based on algal growth, following the OECD protocol (201), to increase the capacity of ecotoxicological testing. Based on mixture toxicity modeling, five pesticides (three herbicides and two fungicides) with different modes of actin (MoA) were identified as the toxicity drivers in studied rivers. The toxicity of these compounds on algae is tested in two settings: single compounds exposure *vs.*artificial mixture. This will allow us to validate the precision and utility of the current prediction models - concentration addition (CA) and independent action (IA) - that are based on a single-species approach. The same workflow will be used to generate ecotoxicity data for five different species of freshwater algae from distant phylogenetic groups (i.e. Chlorophyta, Rhodophyta, Bacillariophyta, Cyanophyta and Chrysophyta), in order to produce species sensitivity distribution curves (SSD) and infer a community approach. The SSD approach is of particular interest since different species are expected to present different sensitivities to toxicity drivers (with different MoA) when exposed alone and in combination. Mixture toxicity modelling combined with the SSD approach might give us new insights on how to expand the mixture toxicity risk assessment for algae on a community level and use this tool for a better protection of the aquatic environment.

MO171
A recipe for the development of High-Accuracy QSAR models based on toxic mechanisms of action
P. Bicherel, F. Sahigara, KREATiS; P. Thomas, CEHTRA SAS / Ecotoxicology and Risk Assessment; F. Bauer, KREATiS
Often, the ultimate objective of the QSAR model is to prioritise chemicals for further testing rather than to predict an exact experimental value. Therefore most of the QSAR models are developped for screening pruposes and tend to lack the precision required to replace experimental studies. The OECD settled five criteria of validity to ensure the reliability of a model, and its prediction consequently. However these conditions remain general, plus they are not always and completely satisfied in practice. For this reason, it seems necessary to distinguish between QSAR models created to provide approximations of experimental values and those specially designed to substitute for specific experimental endpoints, the High-Accuracy QSAR models (HA-QSARs). In order to develop this kind of models, the five validation criteria of the OECD need to be elucidated and specified. Furthermore, the mecanistic explanation suggested as facultative appears to be critical, especially in the field of the toxicology. Recommandations are given here to base the models on toxic Mechanism of Action (MechoA) instead of the chemical structure. The aquatic toxicity predicted with commonly used QSARs and HA-QSAR is compared to experimental values which have been validated to be reliable. The analysis shows that the HA-QSAR gets closer result than others to those reference values. Enough confidence can be granted to HA-QSARs to such an extent that they should be considered as serious candidate to remplace experimental test when it is not necessary. [PB1]Abstract. MO172
Why the margin of safety in first tier risk assessment is meaningless - A comparison of first tier with results from realistic TDTK and population modelling
J. Kleinmann, WSC Scientific GmbH; M. Wang, WSC Scientific GmbH / Dept Efate Modelling
In first tier risk assessment of birds and mammals, the risk posed by pesticides to species is indicated by the LD_{50} of a toxic substance and the daily dietary dose of the corresponding species. A safety factor of ten is applied to cover any uncertainty (e.g. regarding inter-species variability and the uncertainty about the slope of the dose response curve). While one might interpret this safety factor as a margin of safety, in reality the margin of safety can be very different from this safety factor. Many substance specific properties, which may strongly influence the risk (e.g. dose-response curve, uptake and elimination rates), are completely ignored but may be critical for the risk. In the first tier the risk is considered to be low, if the DDD of the assessed species is ten times lower than the LD_{50} of the substance. However, since the LD50 is not a “safe dose”, such as e.g. the NOAEL, it is not possible to identify the margin of safety in this calculation. To quantify the margin of safety of the first-tier risk assessment, an existing population modelling framework (POLARIS) has been combined with a TKTD model (GUTS) to simulate the risk from various toxic substances on populations of wild mammals. It is shown, that the margin of safety of a first tier risk assessment strongly depends on substance specific parameters that are not considered in the first tier.

MO173
Modelling life history traits of amphibia for population modelling
J. Kleinmann, T. Braasch, WSC Scientific GmbH; M. Wang, WSC Scientific GmbH / Dept Efate Modelling
In a recent scientific opinion, EFSA (2017) proposed the inclusion of amphibian and reptile species in the process of pesticide risk assessment. In this opinion, the use of spatially explicit population models together with TK/TD modelling is proposed for six focal species. However, few population models are currently available which can be used in this context. In particular, the specific life history traits of amphibian species distinguish them from other vertebrates (e.g. different breeding and feeding habitats). Therefore, a modelling framework is proposed which can be used to simulate amphibian species in the context of ecological risk assessment. This framework is included in the existing population modelling framework POLARIS to facilitate a flexible risk assessment of various species in different landscapes.

MO174
Effects of landscape structure on PT values and population-level risk
J. Kleinmann, WSC Scientific GmbH; M. Wang, WSC Scientific GmbH / Dept Efate Modelling
In current first tier risk assessment according to EFSA (2009), PT values may be used as a refinement option. These values are mostly derived from field studies. Although these studies can be rather comprehensive and expensive, their sample sizes are often relatively small and consequently samples from different landscapes are sometimes pooled without testing the influence of landscape structure. To overcome these limitations of field studies an existing modelling framework is used to simulate PT values of various species (brown hare *Lepus europaeus*, European rabbit *Oryctolagus cunniculus*, common vole M*icrotus arvalis*) in differently structured agricultural landscapes. It is shown, that PT values strongly depend on the landscape structure and how worst-case landscapes may be chosen for field and modelling studies.

MO175
A common issue: wildlife risk assessment supported by population modelling

- a case study that investigated potential herbicide effects on common vole populations

L. Ibrahim, Rifcon GmbH / Regulatory Afffairs - Population Modelling and Statistics; F.P. Podsedensek, Nufarm GmbH & Co. KG / European Regulatory Lead; A. Van Den Ende, Nufarm Europe GmbH / Head of Countries Regulatory Affairs EuMeA; T. Wittwer, Rifcon GmbH / Regulatory Sciences - Population Modelling and Statistics; F. Bastiansen, Rifcon GmbH; O. Jakoby, Rifcon GmbH / Regulatory Sciences - Population Modelling and Statistics; J. Ludwigs, Rifcon GmbH / Business Development

Environmental risk assessments (ERA) for pesticides usually require higher-tier data for the small herbivorous mammal scenario represented by the vole. Population modelling for a relevant vole species is one way to provide such data. This exemplarily case study conveys all relevant steps that were conducted for a common vole (*Microtus arvalis*) population modelling study for higher-tier ERA. The modelling study evaluated the likelihood of long-term repercussions on common vole populations due to the 2,4-D herbicide uses in grassland. It enhanced the lower-tier standard assessment as well as higher-tier field studies. The population modelling approach, its reasoning and its inclusion into the higher-tier data package was discussed with the evaluating member state authorities. The spatially-explicit individual-based population model, *eVole 3.0,* was used for simulations. It considers ecological processes such as reproduction, mortality and spatial behaviour, which are relevant for common vole population dynamics. Vole individuals in the model live in landscapes that for this study represented grassland in which herbicides were applied. The resulting foliar residues and their fate were simulated. Individuals got exposed via their diet, the assumed main exposure route, i.e. the contaminated grass within their dynamic daily home-ranges. Thus, dietary exposure was estimated in the model following the current EFSA Birds and Mammals Guidance rationale. Individual-level toxicological effects resulted from exposure according to dose-response relationships calibrated from multi-generation rat studies. As a result, the population-level responses emerged from the fates of vole individuals, which constituted the modelled populations. Increased application rates were simulated in addition to the intended rates to demonstrate a margin of safety and to provide positive controls. Finally, the impact of year-on-year herbicide applications in grassland on common vole population density was assessed by comparing treatment simulations to control simulations. Treatment-related population-level effects were evaluated and, where relevant, the time needed to achieve population recovery following the cessation of herbicide applications was determined. The study design and results reporting were guided by EFSA scientific opinions on good modelling practice and on recovery in ERA.

MO176

Can individual-based models with reduced complexity predict rotifer population dynamics under copper stress?

K. Viaene, ARCHE; K. De Schamphelaere, Ghent University (UGent) / Environmental Toxicology; P. Van Sprang, Arche consulting

The extrapolation from individual-level endpoints to the population level remains a critical issue in the ecological risk assessment of chemicals and metals in particular. Population modelling is regarded as a promising tool to bridge this gap. Individual based models based on dynamic energy budget theory (DEB-IBM) in particular are proposed as the “missing link” between the individual and the population level. Model complexity is however a hurdle for their implementation as regulatory tools because this limits the interpretability and transparency of model predictions when evaluating the model. In the current study, a DEB-IBM with reduced complexity (DEBkiss-IBM) was used to simulate effects of copper on populations of the rotifer *Brachionus calyciflorus*. DEBkiss follows a strict set of assumptions that reduce the complexity of a full DEB model e.g. by omission of maturity and reserve dynamics. The DEBkiss-IBM was calibrated at the individual-level and validated using independent datasets. Lethal effects were simulated using the General Unified Threshold model for Survival (GUTS). Sub-lethal effects on reproduction were modelled following the DEBtox principles and the physiological mode of action was determined. Both models were evaluated using independent datasets containing survival and reproduction data under copper stress. As a final validation step, population dynamics were simulated under different copper stress conditions and validated with data from a 28-days population experiment. The DEBkiss-IBM was able to succesfully predict rotifer population dynamics under copper stress. For species where the DEBkiss assumptions are valid e.g. species with a short life cycle that lack a significant reserve compartment, DEBkiss-IBMs could be used as a valid alternative to more complex DEB-IBMs, possibly easing their regulatory acceptance and use.

MO177

Population modelling to assess the effects of a copper pesticide on rainbow trout (Oncorhynchus mykiss)

S.D. Janssen, Ghent University (UGent) / Vakgroep Dierwetenschappen en Aquatische Ecologie; K. Viaene, ARCHE; P. Van Sprang, Arche consulting; K. De Schamphelaere, Ghent University (UGent) / Environmental Toxicology

Currently, ecological risk assessment at lower tiers is mostly based on laboratory toxicity tests that measure the effect of pesticides on individual-level endpoints. Mortality, dry weight, biomass, fecundity and hatchability are individual-level endpoints that are often measured in fish toxicity tests. However, individual-level endpoints do not necessarily translate directly to a similar effect at the population level and guidelines based on individual-level endpoints might thus be inadequate for the protection of species at population level. Population models can help to overcome this problem. Therefore, the goal of this study was to extrapolate the effects of a Copper hydroxide WP pesticide on rainbow trout (*Oncorhynchus mykiss*) from a toxicity test to more realistic exposure scenarios, using a population model. To estimate population level effects, an existing individual-based model for brown trout, inSTREAM-Gen was adapted and extended with a toxicity component. Pesticide effects on survival were incorporated in the model using toxicokinetic-toxicodynamic models e.g. the General Unified Threshold for Survival (GUTS) model. These toxicity models are specifically designed to cope with time-varying exposure concentration, which are typical for pesticides. The population model was used to predict population dynamics over a multi-year simulation period and to assess how a realistic exposure to the pesticide is expected to affect this population. To this end, different exposure scenarios were selected where e.g. the number of pesticide applications and the application period were altered. Effect concentrations were derived for a selection of population-level endpoints (e.g. relative population size, probability of persistence) and critically compared with the effect concentrations derived for the individual level. The use of population models and realistic exposure scenarios offers a chance to extrapolate the effects of laboratory toxicity tests to the field based on solid ecological principles. This approach can serve as an intermediate tier tool that utilizes the results of lower tier tests and avoids the costs associated with higher tier multi-species tests.

MO178

Population level risk assessment of copper toxicity to rainbow trout (Oncorhynchus mykiss)

S.D. Janssen, Ghent University (UGent) / Vakgroep Dierwetenschappen en Aquatische Ecologie; K. Viaene, Arche consulting; K. De Schamphelaere, Ghent University (UGent) / Environmental Toxicology

Copper is an essential trace element for organisms. However too high copper concentrations will have toxic effects on organisms. It is therefore important to address the toxic effect of copper in the most accurate way possible. Nowadays, ecological risk assessment of metals is mostly based on laboratory toxicity test that measure the effect of a metal concentration on individual-level endpoints. However, it does not consider how this eventually will affect the population. Different toxic effects will happen simultaneously and may strengthen the effect of a toxicant on population level. On the other hand, population level processes as density dependence may buffer the toxicity effects on population level. Population models can be a promising tool assess the effects of a toxicant on the population level and thereby overcome these problems. Therefore, the aim of this study was to investigate population level effects of copper toxicity to rainbow trout (*Oncorhynchus mykiss*) using a population model. The study aimed to incorporate the bioavailability of copper in the population model. Another focus of the study was to incorporate different sensitivity levels to copper of the different life stages of rainbow trout. To model copper toxicity on the population level of rainbow trout, an already existing individual based model (IBM) for brown trout, inSTREAM-Gen was adapted and extended with a toxicity component. Based on individual-level toxicity data, copper effects on growth and survival of different life stages were included. Survival effects were modelled using the General Unified Threshold for Survival model based on free copper ions. The population model was used to predict relative population sizes over a 10-year simulation period. These predictions were then used to determine population level ECx values based on population density and the probability of persistence of the population after 10 years. \n

MO179

Multi-Model Framework for Assessing Pesticide Risk across Ecological Hierarchies

D.V. Preziosi, B. Sackmann, Y. Atalay, R.A. Pastorok, Integral Consulting, Inc.; J. Davies, Syngenta / Environmental Safety; N. Galic, Syngenta Crop Protection Inc. / Environmental Safety

Population and ecosystem models have a long history of development and use in basic research and resource management. More recently, guidance and case studies have been developed for their use in regulatory risk assessments for legacy chemicals, consumer products, and pesticides. Building on earlier multi-model approaches, we present a 3-phase framework for calibrating population models to the results of pesticide laboratory toxicity tests, then extending to field-population modeling and ecosystem modelling. The modelling framework takes advantage of the plethora of laboratory data created for pesticide registration, and facilitates evaluation of multiple scenarios incorporating environmental realism. The first phase applies population models to laboratory test results to calibrate the models and explore population responses under constant environmental conditions and relatively short simulation periods (e.g., days to weeks). The second phase extends the modelling to assess the potential effects of pesticides on populations subjected to long-term environmental regimes (e.g., time series of water temperature, solar radiation, nutrient and water inflows/outflows, and organism immigration/emigration) and pesticide exposure profiles developed using methods from FOCUS guidance. The third phase of the framework applies ecosystem modelling informed by the calibrations of population models from the two prior phases. AQUATOX (v3.2 beta) is an USEPA approved modelling software used in the third phase of this framework. Single species- and community-level effects (both direct and indirect) resulting from a combination of time-variable pesticide exposure and environmental forcing are evaluated in AQUATOX models for agricultural ditches, ponds, and streams. In addition to improving ecological realism, the multi-model framework can also be used to better inform the design of lab and field experiments and perhaps lessen dependence on them. The multi-model framework is also readily adaptable, in that the choice of a particular model or set of models within one level of an ecological hierarchy (population to community to ecosystem/landscape) may differ across risk assessments and chemicals depending on the non-target species defined in the problem formulation.

MO180

Expected environmental imact from chemicals can be modeled with sufficient accuracy and precision
